#### THOUGHT 1

When a mixture of sodium carbonate and calcium carbonate is fused with silica at 1500°C, a liquid consisting silicates of sodium and calcium is formed. When this liquid is cooled, it becomes viscous and eventually ceases to flow. It becomes solid and called glass. By varying the proportions of the three basic ingredients and by adding other substances, the properties of glass can be altered. An approximate formula for ordinary glass may be given as,

gradustication — e colo decretal deservation de contrata de contra

#### $R_2O-MO-6SiO_2$

where R = Na or K and M = Ca, Ba, Zn and Pb.

SiO<sub>2</sub> may be replaced by Al<sub>2</sub>O<sub>3</sub>, B<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>. Coloured glasses are obtained by adding certain metallic oxides or salts in the fused mass. Glass is attacked by HF and this property is used to make marking on the glass. This is known as etching.

The glass if cooled rapidly becomes brittle and fragile. The articles of glass are cooled neither very slowly nor very rapidly. The articles are cooled gradually. This process is termed annealing.

- 1. Glass is described as a:
  - (a) solid

- (b) liquid
- (c) super cooled liquid
- (d) colloidal solution
- 2. Which acid cannot be stored in glass?
  - (a) HF

(b) HCl

(c) HBr

(d) HI

[Hint: HF attacks glass. Na<sub>2</sub>SiO<sub>3</sub> + 6HF  $\longrightarrow$  Na<sub>2</sub>SiF<sub>6</sub> + 3H<sub>2</sub>O]

- 3. Ordinary glass is:
  - (a) sodium silicate
- (b) potassium silicate
- (c) calcium silicate
- (d) a mixture of sodium and calcium silicates with silica
- 4. Annealing is the best described as:
  - (a) slow and gradual cooling
  - (b) sudden and rapid cooling
  - (c) cooling by water
  - (d) very slow cooling
- 5. A blue colour can be imparted to glass by use of:
  - (a)  $Fe_2O_3$
- (b) CoO

(c) NiO

(d) Cu<sub>2</sub>O

- 6. A special type of glass which contains cerium oxide and does not allow the passage of ultraviolet rays. This glass is used for making lenses. The glass is called:
  - (a) flint glass
- (b) Crooke's glass
- (c) hard glass
- (d) pyrex glass

# THOUGHT 2

Gaseous fuels have become very popular these days. The following are the advantages of gaseous fuels.

- (i) They have high calorific value.
- (ii) They do not produce smoke and leave no ash after combustion.
- (iii) Gaseous fuels can flow through pipes and can be ignited at the moments notice at any place. No special devices are required for their combustion.

Coal gas is a good gaseous fuel as it contains 95% combustible gases such as hydrogen, methane, carbon monoxide, etc. It is obtained by destructive distillation of coal at about 1000°C. Water gas which is essentially a mixture of hydrogen and carbon monoxide is prepared by passing steam over incandescent coke. The reaction is however endothermic. Producer gas which possesses lowest calorific value is prepared by passing air over red hot coke. It contains mainly nitrogen and carbon monoxide. Semiwater gas is a mixture of water gas and producer gas. Oil gas which is used in laboratories is obtained by cracking of kerosene. It is a mixture of hydrocarbons (saturated and unsaturated) mainly lower hydrocarbons. LPG (liquefied petroleum gas), which contains C<sub>3</sub> and C<sub>4</sub> hydrocarbons of the alkane and alkene series supplied in cylinders for domestic uses is very popular these days.

- 1. Which one is the best fuel?
  - (a) Wood
- (b) Coal
- (c) Kerosene
- (d) LPG
- 2. Which gaseous fuel has the highest calorific value?
  - (a) Producer gas
- (b) Semiwater gas
- (c) Coal gas
- (d) Water gas
- **3.** Which of the following contains the highest percentage of carbon monoxide?

- (a) Coal gas
- (b) Water gas
- (c) Producer gas
- (d) Natural gas
- 4. Which of the following is a cracking process?
  - (a)  $C_3H_6 + H_2 \longrightarrow C_3H_8$

  - (b)  $nC_2H_4 \longrightarrow (C_2H_4)_n$ (c)  $C_{16}H_{34} \longrightarrow 6CH_4 + 2C_2H_4 + C_2H_2 + 4C$
  - (d)  $3C_2H_2 \longrightarrow C_6H_6$
- Which gas is essential constituent of the most of fuel gases?
  - (a) CO

(b) CO<sub>2</sub>

(c) N<sub>2</sub>

(d) H<sub>2</sub>O

#### THOUGHT 3

The heavier elements of group 13, 14 and 15 besides their group oxidation state exhibit another oxidation state which is two units lower than the group oxidation state. The stability of lower oxidation state increases down the group.

The display of lower oxidation state is due to inert pair effect.

- 1. Which of the halide does not exist?
  - (a) TICl

- (b) PbBr<sub>4</sub>
- (c) PbCl<sub>2</sub>
- (d) SnCl<sub>2</sub>

- (d) In Tl + 1 oxidation state is more stable than +3 oxidation
  - 3. The strongest reducing agent among the following is:

(b) In Ga + 3 oxidation state is more stable than +1 oxidation

(c) In Sn + 2 oxidation state is more stable than +4 oxidation

2. Which of the following statements is incorrect?

(a) Boron shows only +3 oxidation state.

(a) GeCl<sub>2</sub>

state.

- (b) SnCl<sub>2</sub>
- (c) PbCl<sub>2</sub>
- (d) TICI
- 4. The strongest oxidising agent among the following is:

(b) GeO2

(c) SnO<sub>2</sub>

- (d) PbO<sub>2</sub>
- 5. Inert pair effect is not exhibited by:
  - (a) Pb

(b) Bi

(c) Tl

- (d) B
- 6. Which of the following compounds do not undergo disproportionation in aqueous solution?
  - (a) TlCl<sub>3</sub>

(b) GaCl

(c) InCl

(d) TICI

4. (a) Thought 1 1. (c) 2. (a) 3. (d) 5. (b) 6. (b) Thought 2 1. (d) 2. (c) 3. (b) 4. (c) 5. (a) Thought 3 1. (b) 2. (c) 3. (a) 4. (d) 5. (d) 6. (a, d)

#### **BRAIN STORMING PROBLEMS**

- 1. Which among the following halides is coloured and why? CCl<sub>4</sub>, SiBr<sub>4</sub> and SnI<sub>4</sub>.
  - [Ans. SnI<sub>4</sub> yellow/orange solid]
- 2. Which crystalline allotropic form of carbon has the lowest energy?
  - [Ans. Graphite—It has  $3\sigma$  and  $\pi$ -bond whereas in diamond there are 4 $\sigma$ -bonds. Thus, graphite has low energy.]
- 3. What are the differences in following two classes of carbides? Class 1. Be<sub>2</sub>C, Al<sub>4</sub>C<sub>3</sub>
  - Class 2.  $CaC_2$ ,  $Al_2C_6$
  - [Ans. Class 1. Carbides are methanides because they evolve methane gas on hydrolysis.
    - Class 2. Carbides are called acetylides because they evolve acetylene on hydrolysis.]
- 4. What do you understand by semiwater gas?
  - [Ans. Mixture of producer and water gas is called semiwater gas.]
- 5. Explain the structure of C<sub>3</sub>O<sub>2</sub> in terms of bonding in the molecule.
  - [Ans. It is carbon suboxide with following linear structure,

$$0 = C = C = C = 0$$

Each carbon lies in sp hybrid state. The  $\pi$ -electrons are delocalized from one end to other. The delocalization does not alter the geometry of molecule.]

- **6.**  $\operatorname{Sn}^{2+}(aq.)$  may also be written as  $\left[\operatorname{Sn}(H_2O)_6\right]^{2+}$ , this ion is acidic by hydrolysis, write a possible equation for this hydrolysis.
- 7. Which among the following oxides of lead is strong oxidising agent?

- [Ans. PbO<sub>2</sub>—It oxidises HCl to Cl<sub>2</sub>]
- **8.** Which method is used to get semiconductor grade silicon? [Ans. Zone refining]
- **9.** What is peculiarity in electrical property of quartz?
  - Quartz crystals exhibit piezoelectric effect. Compression of the crystal in particular direction causes an electric voltage to develop across. Such crystals are used in phonograph; microphones to convert sound vibrations to alternating electric current. The opposite effect is also possible; the alternating current when applied to piezoelectric crystal can make it to vibrate.]
- 10. Which of the following oxides of carbon act as a reducing agent and why?

$$CO, CO_2, C_3O_2$$

[Ans. CO; there is lone pair of  $e^-$  at carbon to be denoted; hence carbon monoxide acts as reducing agent.]

11. Classify the following silicates:

(a) Beryl (b) Feldspar (c) Spodumene (d) Zircon [Ans. (a) Cyclic, (b) Three dimensional sheet, (c) Chain silicate, (d) Orthosilicate]

(u) Offilosificate

12. Explain why the silicate olivine (FeMg)<sub>2</sub>SiO<sub>4</sub> does not follow the law of constant composition.

[Ans. Any ratio of iron to magnesium may be found. It may be treated as solution of Fe<sub>2</sub>SiO<sub>4</sub> in Mg<sub>2</sub>SiO<sub>4</sub> and *vice-versa*.]

13. What are the following compounds? Give their uses:

(i) Vitrosil

(ii) Carbogen

(iii) Kieselguhr

(iv) Chrome yellow and chrome red

(v) Butter of tin

(vi) Litharge and Massicot

(vii) Carburated water gas

(viii) Crooke's glass

(ix) Opal glass

[Ans.

(i) Quartz glass used in the manufacture of optical instruments is called **vitrosil**.

(ii) Carbogen is a mixture of 95% O<sub>2</sub> and 5% CO<sub>2</sub>. It is used for artificial respiration for the victims of carbon monoxide poisoning.

(iii) Kieselguhr—It is a mass of hydrated silica (SiO<sub>2</sub>) formed from skeletons of minute plants known as diatoms. It is highly porous and absorbent material used in the manufacture of dynamite.

(iv) Chrome yellow (PbCrO<sub>4</sub>) is used as yellow pigment chrome red (PbCrO<sub>4</sub> PbO) is used as red pigment.

(v) SnCl<sub>4</sub>·5H<sub>2</sub>O is called butter of tin and is used as a mordant in dyeing.

(vi) Red form of PbO is called litharge and yellow form of PbO is called massicot.

(vii) Carburated water gas is a mixture of carbon monoxide (23-28%); H<sub>2</sub> (34-38%), saturated hydrocarbons (17-21 %),

unsaturated hydrocarbons (13–16%);  $CO_2$  (upto 2%) and  $(N_2$  upto 5%).

(viii) Crooke's glass is used in UV filter glasses. It contains CeO<sub>2</sub>.

(ix) Sometimes CaF<sub>2</sub> is added to obtain opal glass.]

**14.** Give the names of ions that produce deep blue, light blue, ruby red, green colour and yellow-brown colour in the glass.

[Ans. Colour
Deep blue
Light blue
Ruby red
Green colour
Yellow-brown

Metal ions

Co<sup>2+</sup>

Cu<sup>2+</sup>

Cu +/Cu<sup>2+</sup>

Mixture of Fe<sup>2+</sup> and Fe<sup>3+</sup> ions

**15.** Give the molecular formula of talc and muscovite. Comment on their structure and use.

[Ans. Talc: Mg<sub>3</sub> Si<sub>4</sub>O<sub>10</sub>(OH)<sub>2</sub>. It is one of the very soft material. It is used in talcum powder.

Muscovite: KAl<sub>2</sub> Si<sub>3</sub>AlO<sub>10</sub>(OH)<sub>2</sub>; it is a mica. It has layer type structure involving weak van der Waals' force.

16. Complete the following road map.

$$H_2C_2O_4 \xrightarrow{Conc. H_2SO_4} (A) + (B) + (C)$$
 $Gas Gas Liquid$ 

Gas (A) burns with blue flame and gas (B) turns lime water milky. Gas (A) on oxidation gives gas (B). Liquid (C) produces blue colour when comes in contact with anhydrous copper sulphate.

$$(A) + \operatorname{Cl}_2 \longrightarrow (D) \xrightarrow{\operatorname{NH}_3} (E)$$

$$(B) \xrightarrow{\operatorname{NH}_3} \Delta$$

What are the compounds (A) to (E)?

[Ans. (A) CO; (B) CO<sub>2</sub>; (C) H<sub>2</sub>O; (D) COCl<sub>2</sub>; (E) NH<sub>2</sub>CONH<sub>2</sub>]

# THURSANGAMES Type Duestions

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. The bond order of carbon monoxide is:
- 2. What is the value of x in the following silicate mineral?  $Be_3Al_2Si_xO_{18}$
- 3. The ratio of copper and tin in bell metal alloy is:
- **4.** Pb<sub>3</sub>O<sub>4</sub> is regarded as a compound oxide of PbO and PbO<sub>2</sub>. How many parts of PbO are present in it?
- 5. How many methanides are present in the following carbides? SiC, CaC<sub>2</sub>, Be<sub>2</sub>C, Al<sub>2</sub>C<sub>6</sub>, Al<sub>4</sub>C<sub>3</sub>, B<sub>4</sub>C
- **6.** Carbogen is a mixture of O<sub>2</sub> and CO<sub>2</sub>. It is used for artificial respiration. What is the percentage of CO<sub>2</sub> in this mixture?
- 7. In the giant structure of silica, each silicon atom is surrounded by how many oxygen atoms?

#### Auswers

1. (3)  $KK(\sigma 2s)^2 (\overset{*}{\sigma} 2s)^2 (\pi 2p_x)^2 (\pi 2p_y)^2 (\sigma 2p_z)^2$ Bond order =  $\frac{10-4}{2}$  = 3

- **2.** (6)
- 3. (4) Cu 80% Sn 20% ratio = 80/20 = 4

- 4. (2) 2 parts PbO and 1 part PbO<sub>2</sub>.
- 5. (2) Be<sub>2</sub>C and Al<sub>4</sub>C<sub>3</sub> are methanides.
- 6. (5) 95% O<sub>2</sub> and 5% CO<sub>2</sub>.
- 7. (4) Each silicon atom is surrounded by four oxygen atoms tetrahedrally.

#### 10.1 POSITION IN PERIODIC TABLE

VA group or 15th group of the extended form of the periodic table consists of six elements—nitrogen (N), phosphorus (P), arsenic (As), antimony (Sb), bismuth (Bi) and ununpentium (Uup)\*. This group of six elements constitutes a family. These elements are collectively known as **pnictogens**. These are p-block elements as the last differentiating electron is accommodated on np shell. These elements have five electrons in the valency shell. The elements of the group possess the same electronic configuration and show similarities as well as gradation in their properties with rise of atomic number from nitrogen to ununpentium. Thus, their inclusion in the same group is justified on the basis of electronic configuration and physical and chemical properties which are given below:

**1. Electronic configuration**: The distribution of electrons in various energy shells of the atoms of these elements is given below:

Element	At. No.		Electronic configuration	Inert gas core
N	7	2, 5	$1s^2$ , $2s^2$ $2p^3$	[He] $2s^2 2p^3$
P	15	2, 8, 5	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^3$	[Ne] $3s^2 3p^3$
As	33	2, 8, 18, 5	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^3$	[Ar] $3d^{10}$ , $4s^2 4p^3$
Sb	51	2, 8, 18, 18, 5	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ , $5s^2$ $5p^3$	[Kr] $4d^{10}$ , $5s^2$ $5p^3$
Bi	83	2, 8, 18, 32, 18, 5	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ $4f^{14}$ , $5s^2$ $5p^6$ $5d^{10}$ , $6s^2$ $6p^3$	[Xe] $4f^{14}$ , $5d^{10}$ , $6s^2$ $6p$
Uup	115	2, 8, 18, 32, 32, 18, 5	$5  ext{ } 1s^2, \ 2s^2 \ 2p^6, \ 3s^2 \ 3p^6 \ 3d^{10}, \ 4s^2 \ 4p^6 \ 4d^{10} \ 4f^{14}, \ 5s^2 \ 5p^6 \ 5d^{10} \ 5f^{14},$	[Rn] $5f^{14}$ , $6d^{10}$ , $7s^2$ $7p$
			$(6s^2 6p^6 6d^{10}, 7s^2 7p^3)$	

<sup>\*</sup>Ununpentium (115) has recently been discovered. It is a synthetic element. It is radioactive and is unstable in nature. Very little is known about its properties.

The configurations show that these elements have same number of electrons in the valency shell, *i.e.*, 5 electrons in the valency shell, two of which are in s-orbital and remaining three in three p-orbitals. Thus, they have  $ns^2 np^3$  configuration, *i.e.*, s-orbital is paired and three p-orbitals are unpaired.

The penultimate shell, in nitrogen contains 2 electrons (saturated), in phosphorus contains 8 electrons (saturated), in arsenic contains 18 electrons (saturated) while in antimony and bismuth contain 18 electrons (unsaturated) each. This shows why nitrogen differs from phosphorus in some respects and these two differ from the remaining elements of this group.

In accordance with the Hund's rule, electronic configurations involving fully filled or exactly half filled orbitals are the most stable, the elements of group VA, having exactly half filled orbitals, are also fairly stable and not so reactive. Nitrogen behaves as a **noble element** under ordinary conditions.

#### 2. Similarities and gradation in physical properties :

(a) Metallic and non-metallic character: Metallic nature increases as the atomic number increases. N and P are purely non-metals while Sb and Bi are metals. Arsenic behaves as a metalloid.

N and P combine with electropositive elements and form nitrides and phosphides, respectively. Nitrides are more stable than phosphides. Bi and Sb form alloys with other metals. Thus, N and P are non-metals while Sb and Bi are metals.

- (b) Physical state: There is a gradual change in physical state of these elements under ordinary conditions. Nitrogen, the first element, is a gas while phosphorus, the second member, though a solid, can pass readily into vapour state. It is soft waxy solid. The remaining elements are solids. These are hard and possess metallic lustre.
- (c) Atomic radii: The atomic radii of the elements of group 15 are smaller as compared to the elements of group 14 in the corresponding periods.

$$N < C$$
;  $P < Si$ ;  $As < Ge$  (70 pm) (77 pm) (110 pm) (118 pm) (121 pm) (122 pm)

This is due to increased effective nuclear charge which brings contraction in size.

Atomic radii increase on going down the group.

The increase is due to addition of a new energy shell in each succeeding element.

There is considerable increase in covalent radius from N to P but from As to Bi only a small increase is observed.

The considerable increase in covalent radius from N to P can be attributed to strong shielding effect of s- and p- electrons present in the inner shells. Small increase in covalent radii from As to Bi is, however, due to poor shielding effect of d- and/ or f-electrons present in the inner shells on valency electrons. This brings increase in effective nuclear charge which reduces the effect of the addition of a new energy shell to some extent.

(d) Ionisation energy or Ionisation enthalpy: The values of first ionisation energy are higher than the corresponding group 14 elements. However, the values gradually decrease on going down the group from nitrogen to bismuth.

On account of increased nuclear charge, reduced atomic radii and stable half filled configurations, it is more difficult to remove an electron as it is more tightly held by the nucleus. Subsequently, the values of ionisation energy of these elements are higher than the elements of group 14. The decrease in the values of ionisation energy from nitrogen to bismuth is due to gradual increase in atomic size.

The ionisation energy of nitrogen is very high; this is due to its small size. The difference between N and P is comparatively high but the difference afterwards between two consecutive members is small. This is due to less shielding effect of d-electrons in As and Sb, d and f-electrons in Bi.

Successive ionisation energies of these elements increase as expected, *i.e.*,  $E_1 < E_2 < E_3$ .

Element		N	P	As	Sb	Bi
Ionisation energy	$E_1$	1402	1012	947	834	703
(kJ mol <sup>-1</sup> )	$E_2$	2856	1903	1798	1595	1610
	$E_3$	4577	2910	2736	2443	2466

(e) Electronegativity: Electronegativity decreases gradually on descending the group from N to Bi.

Nitrogen is most electronegative element, i.e., typical non-metal

(f) Density: It increases gradually on descending the group.

Element N P As Sb Bi

Density (g/mL) 0.809 1.823 5.73 6.62 9.78

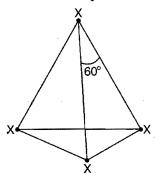

- (g) Allotropy: All the elements except bismuth show allotropy. Nitrogen exists in two solid allotropic forms,  $\alpha$ -nitrogen with cubic crystalline structure and  $\beta$ -nitrogen with hexagonal crystalline structure. The transition temperature is  $-238.5^{\circ}$ C. Phosphorus exists in number of allotropic forms such as white, red, scarlet,  $\alpha$ -black,  $\beta$ -black and violet. Arsenic is known in three allotropic forms, *i.e.*, grey, yellow and black. Antimony also exists in three forms, *i.e.*, yellow, black and explosive.
- (h) Catenation: N, P and As exhibit the property of catenation but this property is much less than IVA elements. No nitrogen compound containing nitrogen chain with more than two atoms is stable although compounds having a chain of eight nitrogen atoms have been prepared. The bond energies of C—C, N—N, P—P and As—As linkages are 85.0, 48.0,

39.0 and 35.0 kcal/mol. Thus, the tendency of catenation decreases from N to P and from P to As. P and As can form a chain of only two atoms.

(i) Atomicity: Nitrogen is diatomic gaseous molecule at ordinary temperature. The existence of nitrogen as diatomic molecule is due to its ability to form multiple bonds. The molecule has one sigma and two  $\pi$ -bonds.

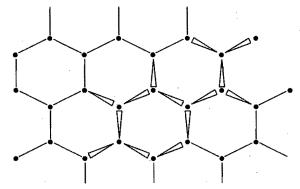

$$: N : N : or N : N = N : (N2)$$

The triple bond in nitrogen molecule is very stable as the dissociation energy is very high (225 kcal/mol). It is, therefore, inert under ordinary conditions.

**Fig. 10.1** X = P, As or Sb

Phosphorus, arsenic and antimony all exist as discrete tetratomic tetrahedral molecules, viz.,  $P_4$ ,  $As_4$  and  $Sb_4$  (Fig. 10.1) as these are not capable of forming multiple bonds due to repulsion between non-bonded electrons of the inner core. The angle between X-X-X is  $60^\circ$ . The  $p\pi-p\pi$  bonding in phosphorus, arsenic, etc., is therefore not possible. Elements of this group form giant lattice in which bonding changes from covalent to metallic, e.g., violet and red phosphorus has layer structure involving covalent bonding. Bismuth on the other hand involves purely metallic bonding. Metallic layer structure of bismuth is given below:

(j) Oxidation states: The elements of this group have five electrons in their outer shell. They exhibit a maximum oxidation state of +5 towards oxygen by using all the five electrons of outer shell. The tendency of the pair of ns electrons to remain inert (the inert pair effect) increases with increase of atomic number. Thus, only the p-electrons are used in bonding, i.e., +3 oxidation state is observed. +3 and +5 oxidation states

of these elements are observed with halogens and sulphur. The stability of +3 oxidation state increases and that of +5 oxidation state decreases on moving down from N to Bi.

Nitrogen and phosphorus generally exhibit -3 oxidation state due to high electronegativity and small size. Nitrogen forms nitride ion ( $N^{3-}$ ) with highly electropositive elements. Phosphorus also forms phosphide ion ( $P^{3-}$ ) to some extent. The tendency to show -3 oxidation state decreases from nitrogen to bismuth.

Note: Nitrogen besides -3, +3 and +5 oxidation states, exhibits a large number of oxidation states from -3 to +5; -3 in NH<sub>3</sub> and nitrides (Li<sub>3</sub>N, Ca<sub>3</sub>N<sub>2</sub>, AlN), -2 in NH<sub>2</sub>NH<sub>2</sub>, -1 in NH<sub>2</sub>OH, 0 in N<sub>2</sub>, +1 in N<sub>2</sub>O, +2 in NO, +3 in N<sub>2</sub>O<sub>3</sub> and HNO<sub>2</sub>, +4 in NO<sub>2</sub> and +5 in HNO<sub>3</sub> and N<sub>2</sub>O<sub>5</sub>.

**Disproportionation:** All the oxidation states of nitrogen from +1 to +4 show disproportionation in acidic medium. For example,

$$^{+3}_{3\text{HNO}_2} \xrightarrow{+5} ^{+2}_{100} + \text{H}_{20}$$

Phosphorus exhibits disproportionation in all the intermediate oxidation states from -3 to +5 in acidic and basic mediums. For example,

$$2H_{3}PO_{2} \xrightarrow{\text{Heat}} H_{3}PO_{4} + PH_{3}$$

$$+3 \xrightarrow{+5} -3$$

$$4H_{3}PO_{3} \longrightarrow 3H_{3}PO_{4} + PH_{3}$$

This tendency decreases from As to Bi due to inert pair effect as stability of +3 state increases from As to Bi.

(k) Valency and nature of bonding: There are five electrons present in the valence shell of these elements. To achieve stable configuration, they require three more electrons which is not easy to accept as to form trinegative ion  $(M^{3-})$ due to energy considerations. Such an ion is formed by nitrogen which is smallest and most electronegative element of the family when it combines with highly electropositive metals. This tendency is much less in phosphorus. These elements easily attain stable configuration by sharing three p-electrons, i.e., by forming three covalent bonds. Except nitrogen, all other elements have d-orbitals in the valence shell. As a result, one of the two ns-electrons may be promoted to nd-orbitals to have five unpaired orbitals in the valence shell. These can be used to form five covalent bonds. This is not possible in nitrogen as it has no d-orbitals (nitrogen never shows pentavalency). However, nitrogen can show a maximum covalency of 4 when it donates the *ns*-electron pair to Lewis acids.

Sb and Bi can lose three electrons forming  $M^{3+}$  ions but ionisation energy is too high for the other elements. Both SbF<sub>3</sub> and BiF<sub>3</sub>, exist as ionic solids. The  $M^{3+}$  ions are not very stable in solution. They can exist in fairly strong acid solution but are rapidly hydrolysed in water to give the antimony oxide ion or bismuth oxide ion, SbO<sup>+</sup> and BiO<sup>+</sup>. The change is reversed by adding 5M HCl.

$$Bi^{3+} \stackrel{H_2O}{\rightleftharpoons} [BiO]^+ + 2H^+$$

$$BiCl_3 + H_2O \longrightarrow BiOCl + 2HCl$$

$$Sb^{3+} + H_2O \rightleftharpoons [SbO]^+ + 2H^+$$
Antimonyl ion

**Multiple bonding:** Nitrogen forms  $p\pi - p\pi$  multiple bonds easily with itself and also with carbon and oxygen. Nitrogen exists as triply bonded diatomic gaseous molecule (N=N) at ordinary temperature. The bond strength is very high (941.4) kJ mol<sup>-1</sup>) and this is responsible for its inertness at ordinary conditions. Other members show reluctance to form multiple bonds. However, phosphorus can form  $p\pi$ - $d\pi$  type multiple bonds, e.g.,  $O = PX_3$ ,  $RN = PX_3$ .

Maximum covalency: The maximum covalency of nitrogen is four as it does not possess d-orbitals in the valence shell, i.e., it cannot extend its valency beyond four [NH<sub>4</sub>,  $R_4N^+$ ]. On the other hand, other members have empty d-orbitals and can utilise these orbitals to show covalency of five or six, e.g., PCl<sub>5</sub>, [SbF<sub>6</sub>].

(1) Thermal and electrical conductivity: Both these properties increase on moving down the group because delocalization of electrons increases from nitrogen to bismuth.

- 3. Occurrence: Nitrogen is found in free as well as in combined state. Nitrogen forms 75% by mass and 78% by volume of the atmosphere. In the combined state, it occurs as nitrates, proteins, amino acids, etc. Phosphorus does not occur free in nature. Phosphorus is the eleventh most abundant element in the earth's crust. Phosphorus is essential for life of both plants and animals. About 60% of bones and teeth are Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> or [3{Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>}.CaF<sub>2</sub>] and an average person has 3.5 kg of calcium phosphate in his body. Phosphorus is present, in DNA, RNA, ATP, ADP, etc. It is also found as phosphates in nature. As, Sb and Bi are not abundant. They occur as sulphides or oxides.
- 4. Chemical properties: Elements of this group differ from one another appreciably in their chemical activity. Nitrogen is chemically inert under ordinary conditions. Due to this reason, it is found free in atmosphere. The chemical inertness is due to high stability of the triple bond between the two nitrogen atoms. The dissociation energy of the bond is high, i.e., 225 kcal per mole. It is, therefore, at high temperature only when nitrogen can react with other elements.

Phosphorus especially white form is extremely reactive. It readily burns in oxygen to form oxides. The strained structure of P<sub>4</sub> is responsible for high chemical activity. The heavier elements are less reactive as they burn only when heated in air or oxygen to form oxides.

(a) Oxides: All these elements form oxides of the type  $X_2O_3$ ,  $X_2O_4$  and  $X_2O_5$ .

Element Nitrogen Phosphorus Arsenic Antimony Bismuth

Type of oxides				,	. 1
$X_2O_3$	$N_2O_3$	$P_2O_3$	$As_2O_3$	$Sb_2O_3$	Bi <sub>2</sub> O <sub>3</sub>
$X_2O_4$	$N_2O_4$	$P_2O_4$	$As_2O_4$	$Sb_2O_4$	Bi <sub>2</sub> O <sub>4</sub>
$X_2O_5$	$N_2O_5$	$P_2O_5$	$As_2O_5$	$Sb_2O_5$	Bi <sub>2</sub> O <sub>5</sub>

Acidic nature decreases

Greater is the electronegativity more is the acidic character of its oxide. Moreover, among the oxides of same element higher oxidation state is responsible for greater acidic character.

Besides these three types of oxides, nitrogen forms two more oxides N<sub>2</sub>O and NO (these are neutral) and bismuth forms bismuth monoxide (BiO).

#### (i) Acidic nature of each type decreases from nitrogen to bismuth.

N<sub>2</sub>O<sub>3</sub> and P<sub>2</sub>O<sub>3</sub> are acidic, As<sub>2</sub>O<sub>3</sub> and Sb<sub>2</sub>O<sub>3</sub> are amphoteric while Bi<sub>2</sub>O<sub>3</sub> is more basic and less acidic.

$$\begin{array}{c} N_2O_3 + H_2O \longrightarrow 2HNO_2 \text{ (Nitrous acid)} \rightarrow \text{acidic} \\ P_2O_3 + 3H_2O \longrightarrow 2H_3PO_3 \text{ (Phosphorus acid)} \rightarrow \text{acidic} \\ As_2O_3 + 6HCl \longrightarrow 2AsCl_3 + 3H_2O \longrightarrow \text{basic} \\ As_2O_3 + 6NaOH \longrightarrow 2Na_3AsO_3 + 3H_2O \rightarrow \text{acidic} \\ Sb_2O_3 + 6HCl \longrightarrow 2SbCl_3 + 3H_2O \longrightarrow \text{basic} \\ Sb_2O_3 + 6NaOH \longrightarrow 2Na_3SbO_3 + 3H_2O \longrightarrow \text{acidic} \\ Sb_2O_3 + 6NaOH \longrightarrow 2Na_3SbO_3 + 3H_2O \longrightarrow \text{acidic} \\ Bi_2O_3 + 6HCl \longrightarrow 2BiCl_3 + 3H_2O \longrightarrow \text{basic} \\ \end{array}$$

Bi<sub>2</sub>O<sub>3</sub> shows feeble acidic character also as it slightly dissolves in concentrated NaOH solution.

$$Bi_2O_3 + 6NaOH \longrightarrow 2Na_3BiO_3 + 3H_2O$$
Sodium bismuthite

The acidic nature of pentoxides decreases from N<sub>2</sub>O<sub>5</sub> to Bi<sub>2</sub>O<sub>5</sub>·N<sub>2</sub>O<sub>5</sub>, P<sub>2</sub>O<sub>5</sub> and As<sub>2</sub>O<sub>5</sub> are soluble in water and form acids.

$$N_2O_5 + H_2O \longrightarrow 2HNO_3$$
 (Nitric acid)  
 $P_2O_5 + 3H_2O \longrightarrow 2H_3PO_4$  (Orthophosphoric acid)  
 $As_2O_5 + 3H_2O \longrightarrow 2H_3AsO_4$  (Arsenic acid)

Sb<sub>2</sub>O<sub>5</sub> and Bi<sub>2</sub>O<sub>5</sub> are insoluble in water but dissolve in

Acidic nature of  $M_2O_4$  oxides also decreases from  $N_2O_4$  to  $Bi_2O_4$ . The acidic nature of these oxides is less than  $X_2O_5$  type and more than  $X_2O_3$  type. The decrease in acidic nature of the oxides from nitrogen to bismuth is due to decrease in nonmetallic character and increase in metallic character from N to Bi.

(ii) In the oxides of a particular element, the acidic nature increases as the percentage of oxygen increases or as the oxidation state increases. For example, N2O5 is most acidic while N<sub>2</sub>O<sub>3</sub> is less acidic, similarly P<sub>2</sub>O<sub>5</sub> is more acidic than  $P_2O_3$  and  $P_2O_4$ .

$$N_2O_3 + H_2O \longrightarrow 2HNO_2$$
  
 $N_2O_4 + H_2O \longrightarrow HNO_2 + HNO_3$   
 $N_2O_5 + H_2O \longrightarrow 2HNO_3$ 

HNO<sub>3</sub> is stronger than HNO<sub>2</sub>.

$$P_2O_3 + 3H_2O \longrightarrow 2H_3PO_3$$
  
 $P_2O_4 + 3H_2O \longrightarrow H_3PO_4 + H_3PO_3$   
 $P_2O_5 + 3H_2O \longrightarrow 2H_3PO_4$ 

H<sub>3</sub>PO<sub>4</sub> is stronger than H<sub>3</sub>PO<sub>3</sub>.

(iii) Stability of oxides of higher oxidation states decreases with increasing atomic number.

Thermal stability decreases in each series from N to Bi  $N_2O_3$  is most stable oxide. It is more stable than other oxides.  $N_2O_5$  is less stable. However,  $P_2O_5$  is thermally stable, but  $As_2O_5$  and  $Sb_2O_5$  are less stable.  $Bi_2O_5$  is least stable. Except  $P_2O_5$ , all the pentoxides show oxidising properties.  $N_2O_5$  is the strongest oxidising agent.

Nitrogen forms two more oxides, nitrous oxide ( $N_2O$ ) and nitric oxide (NO). Both are neutral in nature. Structurally, the oxides of nitrogen are different from the oxides of the rest of the elements of this group. This is due to the fact that only nitrogen is able to form  $p\pi$ - $p\pi$  multiple bonds which are present in its oxides. The rest of the elements do not form multiple bonds and prefer to form cage structures for their oxides.

(b) Oxyacids: All the elements of this group form oxyacids. Nitrogen forms a number of oxyacids but two common oxyacids are—nitrous acid (HNO<sub>2</sub>) and nitric acid (HNO<sub>3</sub>). Nitric acid is a stable acid while HNO<sub>2</sub> is unstable. Phosphorus forms a large number of oxyacids. The important oxyacids are:

$H_3PO_2$	$H_3PO_3$	$H_4P_2O_4$
Hypophosphorus	Phosphorus	Hypophosphoric
acid	acid	acid
$H_3PO_4$	$HPO_3$	$H_4P_2O_7$
Orthophosphoric	Metaphosphoric	Pyrophosphoric .
acid	acid	acid

Arsenic forms two oxyacids, H<sub>3</sub>AsO<sub>3</sub> (arsenious acid) and H<sub>3</sub>AsO<sub>4</sub> (arsenic acid). Antimony forms one oxyacid H<sub>3</sub>SbO<sub>3</sub> which exists in solution. Bismuth also forms one stable oxyacid HBiO<sub>3</sub>, meta-bismuthic acid.

The strength and stability of oxyacids having the element in the same oxidation state decreases gradually with decrease in electronegativity of central atom.

(c) **Hydrides:** All the elements of this group form hydrides of the type  $MH_3$ .

(i) All the hydrides are formed by the action of water or dilute acids on binary metallic compounds such as Mg<sub>3</sub>N<sub>2</sub>, Ca<sub>3</sub>P<sub>2</sub>, Zn<sub>3</sub>As<sub>2</sub>, Mg<sub>3</sub>Sb<sub>2</sub> and Mg<sub>3</sub>Bi<sub>2</sub>.

The hydrides are also obtained by reduction of trichlorides of these elements (except that of bismuth) with Zn/acid or LiAlH<sub>4</sub>.

$$4MCl_3 + 3LiAlH_4 \longrightarrow 4MH_3 + 3LiCl + 3AlCl_3$$
  
( $M = N, P, As, Sb$ )

- (ii) All the hydrides are colourless gases. Their smell becomes more and more disagreeable as atomic number increases from N to Bi.
  - (iii) The poisonous nature increases from NH<sub>3</sub> to BiH<sub>3</sub>.
- (iv) NH<sub>3</sub> is highly soluble in water but other hydrides are less soluble.
- (v) The basic character decreases from NH<sub>3</sub> to BiH<sub>3</sub>. The basic nature is due to the presence of lone pair of electrons on the central atom. NH<sub>3</sub> is the strongest electron pair donor due to its small size as the electron density of the electron pair is concentrated over a small region. As the size increases the electron density gets diffused over a large region and hence the ability to donate the electron pair (basic nature) decreases. NH<sub>3</sub> and PH<sub>3</sub> form NH<sub>4</sub><sup>+</sup> and PH<sub>4</sub><sup>+</sup> ions with protons. NH<sub>4</sub><sup>+</sup> is more stable than PH<sub>4</sub><sup>+</sup> ion. PH<sub>3</sub> is less basic than NH<sub>3</sub> while AsH<sub>3</sub>, SbH<sub>3</sub> and BiH<sub>3</sub> are neutral. NH<sub>3</sub> is highly soluble in water while PH<sub>3</sub> is less soluble.

(vi) Thermal stability decreases gradually from NH<sub>3</sub> to BiH<sub>3</sub>. The decomposition temperatures decrease from NH<sub>3</sub> to BiH<sub>3</sub>.

The size of the central atom increases from N to Bi, therefore, the tendency to form a stable covalent bond with small hydrogen atom decreases. As the bond length increases, the strength decreases and therefore, thermal stability decreases.

(vii) The reducing nature increases. This shows that bond strength M—H decreases as electronegativity of M decreases.

NH<sub>3</sub> is a weak reducing agent while AsH<sub>3</sub>, SbH<sub>3</sub> and BiH<sub>3</sub> are powerful reducing agents.

(viii) The shape of these hydrides is pyramidal. The formation is due to  $sp^3$  hybridization of central atom, *i.e.*, forming a tetrahedral configuration. However, on one of tetrahedral positions, a lone pair of electrons is present. The bond angle (HMH) in various hydrides is never equal to ideal tetrahedral angle of 109°28′. The actual bond angles are:

The bond angle in ammonia is less than  $109^{\circ}28'$  due to repulsion between lone pair present on nitrogen atom and bonded pairs of electrons. The decreased bond angle in other hydrides can be explained by the fact that the  $sp^3$  hybridization becomes less and less distinct with increasing size of the central atom, *i.e.*, pure p-orbitals are utilised in M—H bonding.

Bond lengths and bond dissociation energies of the hydrides of group 15 elements are listed below:

Hydride	NH <sub>3</sub>	$PH_3$	AsH <sub>3</sub>	SbH <sub>3</sub>
M-H bond length (pm)	101.7	141.9	151.9	170.7
M-H dissociation energy	391	322	297	255
(kJ mol <sup>-1</sup> )				

- (ix) **Hydrogen bonding:** Hydrogen bonding is present in NH<sub>3</sub> as the electronegativity difference between nitrogen and hydrogen is high and the N—H bond shows polarity. The electronegativity of rest of the elements is nearly equal to hydrogen, hence *M*—H bond is purely covalent and no hydrogen bonding is present in their hydrides.
  - (x) The boiling points of these hydrides vary as follows:

Hydride	$NH_3$	$PH_3$	$AsH_3$	$SbH_3$	$BiH_3$
Boiling point (°C)	-33	-89	-63	<del>9</del>	17

In NH<sub>3</sub>, molecules are associated by hydrogen bonding and thus its boiling is comparatively high in comparison to PH<sub>3</sub> and AsH<sub>3</sub> where no hydrogen bonding is present. In moving from PH<sub>3</sub> to BiH<sub>3</sub>, boiling points increase due to increase in the magnitude of van der Waals' forces due to increase in molecular size.

(d) Halides: The main halides formed by the elements of this group are listed below:

Element	Trihalides	Pentahalides
Nitrogen	NF <sub>3</sub> , NCl <sub>3</sub> , NBr <sub>3</sub> , NI <sub>3</sub>	· · • <u>• · ·</u> • · · • ·
Phosphorus	PF <sub>3</sub> , PCl <sub>3</sub> , PBr <sub>3</sub> , PI <sub>3</sub>	PCl <sub>5</sub> , PF <sub>5</sub> , PBr <sub>5</sub>
Arsenic .	AsF <sub>3</sub> , AsCl <sub>3</sub> , AsBr <sub>3</sub> , AsI <sub>3</sub>	AsF <sub>5</sub>
Antimony	SbF <sub>3</sub> , SbCl <sub>3</sub> , SbBr <sub>3</sub> , SbI <sub>3</sub>	SbF <sub>5</sub> , SbCl <sub>5</sub>
Bismuth	BiF <sub>3</sub> , BiCl <sub>3</sub> , BiBr <sub>3</sub> , BiI <sub>3</sub>	$\mathrm{BiF}_{5}$

All form trihalides. One or more pentahalides are formed by the elements except nitrogen. Nitrogen does not form pentahalides due to absence of *d*-orbitals.

(i) **Trihalides:** The elements directly combine with halogens and form trihalides,  $MX_3$ . All the trihalides are stable except NCl<sub>3</sub>, NBr<sub>3</sub> and NI<sub>3</sub>. The unstable nature of NCl<sub>3</sub>, NBr<sub>3</sub> and NI<sub>3</sub> is due to low polarity of N—X bond and a large difference in the size of nitrogen and halogen atoms.

The trihalides have a tetrahedral structure involving  $sp^3$ -hybridization of the central atom. They have pyramidal shape. A lone pair of electrons is present on the central atom. Due to the presence of a lone pair of electrons on the central atom, they act as Lewis bases. In the case of nitrogen halides, the tendency to act as Lewis base decreases from NI<sub>3</sub> to NF<sub>3</sub>.

$$NI_3 > NBr_3 > NCl_3 > NF_3$$

This is due to increased electronegativity from I to F.

Also the tendency to act as Lewis base decreases from N to Bi for a given halide.

The trihalides of phosphorus and antimony especially fluorides and chlorides act as Lewis acids also by using the vacant *d*-orbitals.

Except NF<sub>3</sub> and PF<sub>3</sub>, all the trihalides are hydrolysed by water.

$$NCl_3 + 3H_2O \longrightarrow NH_3 + 3HClO$$
  
 $PCl_3 + 3H_2O \longrightarrow H_3PO_3 + 3HCl$   
 $AsCl_3 + 3H_2O \longrightarrow H_3AsO_3 + 3HCl$   
 $SbCl_3 + H_2O \Longrightarrow SbOCl + 2HCl$   
 $BiCl_3 + H_2O \Longrightarrow BiOCl + 2HCl$ 

**Note:** The NCl<sub>3</sub> is hydrolysed to a base (NH<sub>3</sub>) while PCl<sub>3</sub> is hydrolysed to an acid (H<sub>3</sub>PO<sub>3</sub>). It is due to the fact that NCl<sub>3</sub> is an electron pair donor while PCl<sub>3</sub> is an acceptor as P has vacant 3*d*-orbitals.

(ii) **Pentahalides:** Phosphorus pentachloride is the most well known of the pentahalides. Bismuth does not form pentahalides because of inert pair effect. The pentahalides have a trigonal bipyramid shape  $(sp^3d$ -hybridization) in gaseous and liquid states which is not very stable structure, hence these pentahalides decompose into stable lower halides.

$$PCl_5 \rightleftharpoons PCl_3 + Cl_2$$

These are also hydrolysed by water.

$$PCl_5$$
 +  $H_2O \longrightarrow POCl_3 + 2HCl$   
 $POCl_3 + 3H_2O \longrightarrow H_3PO_4 + 3HCl$ 

[PCl<sub>5</sub> acts as an effective chlorinating agent.]

X-ray studies have shown that the solid PCl<sub>5</sub> is an ionic compound composed of [PCl<sub>4</sub>]<sup>+</sup> [PCl<sub>6</sub>]<sup>-</sup>. Solid PBr<sub>5</sub> exists as [PBr<sub>4</sub>]<sup>+</sup>Br<sup>-</sup>.

All the pentahalides act as Lewis acids due to the presence of d-orbitals.

$$MX_5 + X^- \longrightarrow [MX_6]^-$$

The hybridization of the central atom (M) changes from  $sp^3d$  to  $sp^3d^2$ .

(e) Sulphides: With the exception of nitrogen, all other elements of this group form sulphides. The sulphides of arsenic and antimony are soluble in yellow ammonium sulphide or ammonium sulphide and form thio-compounds.

Antimony sulphides form similar compounds. The sulphides are also soluble in caustic alkali.

$$As_2S_3 + 6NaOH \longrightarrow Na_3AsS_3 + Na_3AsO_3 + 3H_2O$$
Sodium thio-
arsenite

Sodium
arsenite

The stability of sulphides increases with increase in atomic number of the element.

# 10.22 ABNORMAL BEHAVIOUR OF NITROGEN

Nitrogen differs considerably from the rest of the family members. The differences or abnormal properties are mainly due to the following four factors:

- (a) Small size of nitrogen atom.
- (b) High value of electronegativity.
- (c) Absence of d-orbitals in the valency shell.
- (d) Tendency to form multiple bonds.

The important points in which nitrogen differs from other members of VA group are listed below:

- (i) Nitrogen is a gas while other members are solids.
- (ii) Nitrogen molecule is diatomic (N≡N) while other elements form tetratomic molecules such as P<sub>4</sub>, As<sub>4</sub> and Sb<sub>4</sub>.
- (iii) The catenation property is more pronounced in nitrogen. Chains containing upto eight nitrogen atoms are known but in the case of other elements, catenation is limited to two atoms only.
- (iv) Nitrogen forms five oxides.  $N_2O$  (nitrous oxide), NO (nitric oxide),  $N_2O_3$  (nitrogen trioxide),  $NO_2$  (nitrogen dioxide) and  $N_2O_5$  (nitrogen pentoxide). Others can form at the most three types of oxides,  $X_2O_3$ ,  $X_2O_4$  and  $X_2O_5$ .

 $N_2O_3$  and  $N_2O_5$  are monomeric in nature but oxides of other elements are dimeric.

- (v) Hydride of nitrogen (NH<sub>3</sub>) is stable while the hydrides of other elements are not stable. Hydrogen bonding is present in ammonia (NH<sub>3</sub>) but not present in other hydrides.
- (vi) Except  $NF_3$ , the halides of nitrogen ( $NCl_3$ ,  $NBr_3$  and  $NI_3$ ) are unstable and explosive. The halides of other elements are stable. Unlike P, As and Sb, nitrogen does not form pentahalides.
- (vii) Due to small size and high electronegativity, nitrogen can form trinegative ion  $N^{3-}$ . This tendency is less in P but absent in other elements.
- (viii) As nitrogen does not have *d*-orbitals in its valency shell, its maximum covalency is 3 while in the case of other elements, the maximum covalency is 5.
- (ix) Nitrogen is chemically inert under ordinary atmospheric conditions. This is due to high dissociation energy of nitrogen molecule. The other elements are quite reactive as they have single bonds in their molecules, *i.e.*, dissociation energies are low.
- (x) Nitrogen shows a large number of oxidation states from -3 to +5 such as +1 in  $N_2O_5$ , +2 in  $NO_5$ , +3 in  $N_2O_3$ , +4 in  $NO_2$ , +5 in  $N_2O_5$ , -1 in  $NH_2OH$  and -3 in  $NH_3$ . Other elements show a limited number of oxidation states from -3 to +5.
- (xi) Nitrogen does not form sulphide while all other elements form sulphides.
- (xii) On account of high value of electronegativity, nitrogen behaves as a typical non-metal while As, Sb are metalloids and Bi is a metal.

Nitrogen (N≡N), carbon monoxide C ∓O and cyanide ion (C≡N) are isoelectronic in nature. Nitrogen is inert while other species are active. The bond between nitrogen atoms is non-polar.

#### 10.3 NITROGEN (N<sub>2</sub>)

Scheele, in 1772, showed that air is a mixture of two gases: fire air (oxygen) which supports combustion and respiration and foul air (nitrogen) which does not take part in combustion. D. Rutherford named foul air as mephitic air (killer of life). Later on the element was found to be present in nitre and thus, the name **nitrogen** was proposed.

Occurrence: Nitrogen exists in its elemental form as diatomic molecules (N<sub>2</sub>), it is therefore, called as dinitrogen. Nitrogen is widely distributed in nature both in free as well as in the combined state. Air is the most abundant source of free nitrogen. It forms 75% by mass and 78% by volume of the air. In combined state, it is found as nitrates such as Chile saltpetre (NaNO<sub>3</sub>), Indian saltpetre (KNO<sub>3</sub>) and ammonium compounds. It is an essential constituent of all living things (animals and vegetables both) where it is found in the form of proteins, amino acids and nucleic acids. Its existence in atmosphere is very important because it acts as inert diluent for the highly reactive gas, *i.e.*, oxygen. Without nitrogen, every spark in our atmosphere would cause a massive fire.

**Preparation:** Nitrogen can be obtained from the following two sources:

- (i) Nitrogen compounds and (ii) Air.
- (i) From nitrogen compounds: (a) Nitrogen in the laboratory can be obtained by heating ammonium nitrite or ammonium dichromate. Ammonium nitrite is not a stable compound and thus it is first formed as an intermediate product by heating an ammonium salt with sodium nitrite.

$$\begin{array}{c} NH_4Cl + NaNO_2 \longrightarrow NH_4NO_2 + NaCl \\ \\ NH_4NO_2 \longrightarrow N_2 + 2H_2O \\ \\ (NH_4)_2Cr_2O_7 \longrightarrow N_2 + Cr_2O_3 + 4H_2O \end{array}$$

Nitrogen is collected by downward displacement of water.

(b) Pure nitrogen can be obtained by passing the ammonia vapours over heated CuO.

$$2NH_3 + 3CuO \longrightarrow N_2 + 3Cu + 3H_2O$$

NH<sub>3</sub> can also be oxidised to nitrogen by Cl<sub>2</sub>, Br<sub>2</sub>, a hypochlorite, a hypobromite or bleaching powder. [See for reactions section 10.4.]

(c) It can also be obtained by the action of nitrous acid (or NaNO<sub>2</sub> and dil. H<sub>2</sub>SO<sub>4</sub>) on urea.

$$NH_2CONH_2 + 2HNO_2 \longrightarrow 2N_2 + CO_2 + 3H_2O$$
Urea

(d) Pure nitrogen is obtained in small amount by heating sodium or barium azides in vacuum.

$$Ba(N_3)_2 \longrightarrow 3N_2 + Ba$$

(ii) From air: (a) Air is the major source of nitrogen. Commercially nitrogen is obtained by liquefaction of air. The resultant liquid is fractionally distilled in *Claude's apparatus*.

Air is freed from dust particles and compressed to 60 atmospheres. It is cooled. The compressed air is freed from CO<sub>2</sub> by passing through a tower packed with sodalime and then dried by passing through alumina driers. It is then passed through pipes which are surrounded by cold nitrogen or cold oxygen. The cold compressed air is allowed to do work in Claude's expansion engine when it is partially liquefied. The partially liquefied air is passed through a double rectification column when more of air is liquefied. Liquefied air is further fractionally distilled in Claude's apparatus. Finally, about 90% pure nitrogen escapes through the exit at the top of the apparatus.

(b) By removing oxygen of the air with the use of chemical substances.

Purified air 
$$\longrightarrow$$
 Hot Cu  $\longrightarrow$  Nitrogen  $2\text{Cu} + \text{O}_2 \longrightarrow 2\text{CuO}$  Purified air  $\longrightarrow$  Hot coke  $\longrightarrow$  CO<sub>2</sub>, CO, N<sub>2</sub> CO<sub>2</sub> and CO are removed by usual methods. Purified air  $\longrightarrow$  Phosphorus  $\longrightarrow$  P<sub>2</sub>O<sub>5</sub> + N<sub>2</sub>  $\longrightarrow$  H<sub>2</sub>O

**Properties:** (i) It is a colourless, tasteless and odourless gas. It is slightly lighter than air as its vapour density is 14.0. It is sparingly soluble in water.

- (ii) It is not poisonous in nature but animals do not survive in its atmosphere due to absence of oxygen.
- (iii) It can be liquefied to a colourless liquid (b.pt. -195.8°C). When liquid nitrogen is poured on a table, the liquid sizzles and boils away violently.
- (iv) It does not help in combustion. Nitrogen itself is non-combustible.
- (v) It is chemically inert under ordinary conditions. However, it shows chemical activity under high temperatures.
- (a) Nitrogen combines with oxygen under the influence of very high temperature like electric spark.

$$N_2 + O_2 \stackrel{3000^{\circ}C}{\rightleftharpoons} 2NO \text{ (Nitric oxide)}$$

(b) Nitrogen combines with hydrogen in the presence of a catalyst (finely divided iron) at 200 atmospheres and 400–500°C temperature.

$$N_2 + 3H_2 \Longrightarrow 2NH_3$$
 (Ammonia)

(c) Nitrogen combines with metals at red heat to form nitrides.

$$\begin{array}{l} 6\text{Li} + \text{N}_2 \xrightarrow{\phantom{0}450^{\circ}\text{C}} 2\text{Li}_3\text{N (Lithium nitride)} \\ 3\text{Mg} + \text{N}_2 \xrightarrow{\phantom{0}450^{\circ}\text{C}} \text{Mg}_3\text{N}_2 \text{ (Magnesium nitride)} \\ 2\text{Al} + \text{N}_2 \xrightarrow{\phantom{0}800^{\circ}\text{C}} 2\text{AlN (Aluminium nitride)} \end{array}$$

Non-metals like boron, silicon at bright red heat also combine with nitrogen.

$$2B + N_2 \longrightarrow 2BN$$
 (Boron nitride)  
 $3Si + 2N_2 \longrightarrow Si_3N_4$  (Silicon nitride)

(d) Nitrogen combines with calcium carbide to form calcium cyanamide at 1000°C.

$$CaC_2 + N_2 \longrightarrow CaCN_2 + C$$

The mixture of calcium cyanamide and carbon is technically known as nitrolim.

(e) When nitrogen is passed over heated mixture of alumina and carbon, aluminium nitride is formed.

$$Al_2O_3 + 3C + N_2 \xrightarrow{1273 \text{ K}} 2AlN + 3CO$$

This reaction is used for the purification of alumina ore (Serpeck's process). AlN is hydrolysed with steam.

$$\begin{array}{c} AlN + 3H_2O \longrightarrow Al(OH)_3 + NH_3 \\ & \downarrow \text{Heated} \\ & Al_2O_3 \\ \text{Pure alumina} \end{array}$$

- **Uses:** (i) Nitrogen,  $N_2$ , is a relatively unreactive element because of the stability of the nitrogen-nitrogen triple bond (The N = N bond energy is 942 kJ/mol compared with 167 kJ/mol for the N N bond energy). Therefore, it is used to provide an inert atmosphere in certain metallurgical operations and during welding.
- (ii) Large quantity of nitrogen is used as a blanketing gas, the purpose of which is, to protect a material from oxygen during processing or storage. Thus, electronic components are often made under a nitrogen atmosphere.
  - (iii) It is used for filling electric bulbs.
- (iv) It is used in the manufacture of NH<sub>3</sub>, HNO<sub>3</sub>, CaCN<sub>2</sub> and other nitrogen compounds.
- (v) Liquid nitrogen is used as a refrigerant to freeze foods, to freeze soft or rubbery materials prior to grinding them, and to freeze biological materials. Liquid nitrogen has found wide use in frozen food preparation and preservation during transit.
- (vi) Liquid nitrogen is also a cryogen. It has uses in medicine (cryosurgery), for example in cooling a localized area of skin prior to removal of a wart or other unwanted or pathogenic tissue.

#### Active Nitrogen

When an electric discharge is allowed to pass through nitrogen under very low pressure (about 2 mm), a brilliant luminiscence is observed which persists for sometime after the stoppage of the discharge. It is observed that nitrogen after the discharge is more active. This nitrogen is termed active nitrogen.

This form is not quite stable and gradually changes to normal form. Active nitrogen reacts readily with many metals to form

nitrides. It reacts with a number of non-metals, e.g., sulphur, phosphorus, iodine, etc. It is able to decompose many organic compounds.

$$C_2H_2 + N_2 \longrightarrow C_2N_2 + H_2$$
Active

The exact nature of active nitrogen is not yet known.

#### 10.4 IMPORTANT COMPOUNDS OF NITROGEN

#### 🕾 1. Ammonia

Nitrogen forms three well known hydrides with hydrogen: (i) Ammonia, NH<sub>3</sub>, (ii) Hydrazine, NH<sub>2</sub>.NH<sub>2</sub> (N<sub>2</sub>H<sub>4</sub>), (iii) Hydrazoic acid, N<sub>3</sub>H. Ammonia is the most important of these hydrides.

**Occurrence:**  $_{\mathbf{\ell}}$  NH<sub>3</sub> is found in traces in atmosphere. This is formed by bacterial decomposition of nitrogenous matter of plants and animals. Ammonium salts such as ammonium chloride and ammonium sulphate are found in small amounts in the soil. On certain planets (Jupiter and Saturn), it is found in abundance.

**Discovery:** It was first isolated in 1774 by Priestley by the action of ammonium chloride and lime. It was named alkaline air. Berthelot, in 1788, pointed out that ammonia is a compound of nitrogen and hydrogen. In 1800, Davy established its formula NH<sub>3</sub>.

**Preparation:** (i) Ammonia is obtained on a small scale from ammonium salts which evolve it when heated with caustic soda or lime.

$$NH_4Cl + NaOH \longrightarrow NH_3 + NaCl + H_2O$$
  
 $2NH_4Cl + Ca(OH)_2 \longrightarrow 2NH_3 + CaCl_2 + 2H_2O$   
(Slaked lime)

(ii) Ammonia is formed when ammonium chloride is heated with litharge.

$$2NH_4Cl + PbO \longrightarrow 2NH_3 + PbCl_2 + H_2O$$

(iii) By reacting nitrides with water, ammonia is obtained.

$$\begin{aligned} \text{AlN} + 3\text{H}_2\text{O} &\longrightarrow \text{Al}(\text{OH})_3 + \text{NH}_3 \\ \text{Mg}_3\text{N}_2 + 6\text{H}_2\text{O} &\longrightarrow 3\text{Mg}(\text{OH})_2 + 2\text{NH}_3 \end{aligned}$$

(iv) Ammonia can also be formed by doing reduction of nitrates and nitrites with zinc and caustic soda. Zinc and caustic soda produce nascent hydrogen which reacts with nitrates and nitrites to form ammonia.

$$NaNO_3 + 8H \xrightarrow{Zn/NaOH} NaOH + NH_3 + 2H_2O$$

$$NaNO_2 + 6H \xrightarrow{Zn/NaOH} NaOH + NH_3 + H_2O$$

(v) Calcium cyanamide on hydrolysis evolves ammonia.CaCN<sub>2</sub> + 3H<sub>2</sub>O → CaCO<sub>3</sub> + 2NH<sub>3</sub>

(vi) Ammonia is also obtained by heating ammonium compounds.

$$\begin{array}{ccc} (NH_4)_2SO_4 & \xrightarrow{Heat} NH_3 + & NH_4HSO_4 \\ \text{Ammonium} & & & \text{Ammonium hydrogen} \\ \text{sulphate} & & & \text{sulphate} \end{array}$$

(vii) Urea on treatment with caustic soda forms ammonia.

$$NH_2CONH_2 + 2NaOH \longrightarrow Na_2CO_3 + 2NH_3$$
Urea

**Laboratory preparation:** Ammonia is prepared in the laboratory by heating ammonium chloride with slaked lime,  $Ca(OH)_2$  in the ratio of 3:2 in apparatus shown in Fig. 10.2.

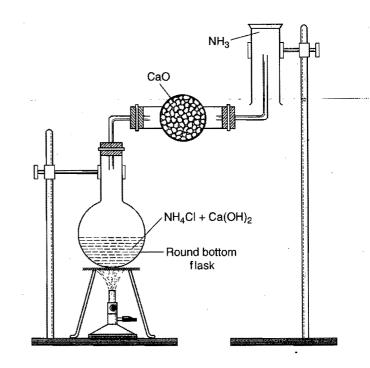

Fig. 10.2 Apparatus for laboratory preparation of ammonia

The mixture is taken in a flask and heated gently. The gas evolved is passed through lime tube and finally collected in a dry jar by downward displacement of air method.

**Precautions:** (i) The apparatus should be air tight.

- (ii) For the collection of gas, dry cylinders should be used as it is very soluble in water.
- (iii) The contents in a flask be covered with a layer of calcium hydroxide as to absorb water otherwise the flask will crack.
- (iv) For drying of ammonia gas, the common dehydrating agents like sulphuric acid or CaCl<sub>2</sub> or P<sub>2</sub>O<sub>5</sub> cannot be used as these react with ammonia.

$$2NH_3 + H_2SO_4 \longrightarrow (NH_4)_2SO_4$$
Ammonium sulphate
$$CaCl_2 + 8NH_3 \longrightarrow CaCl_2 \cdot 8NH_3$$
Addition product
$$P_2O_5 + 6NH_3 + 3H_2O \longrightarrow 2(NH_4)_3PO_4$$
Ammonium phosphate

For drying, quick lime, CaO is used as it does not react with ammonia but reacts readily with moisture.

$$\begin{array}{ccc} \text{CaO} & + \text{H}_2\text{O} \longrightarrow \text{Ca(OH)}_2 \\ \text{Quick lime} \end{array}$$

#### Manufacture of Ammonia

#### (i) Haber process:

**Principle:** Haber process is the most important industrial method of preparing ammonia from  $N_2$  and  $H_2$ . This method was discovered by a German chemist **Fritz Haber** in 1913. He was awarded Nobel Prize in 1918 for this work. The method involves the direct combination of nitrogen and hydrogen according to the following reaction:

$$N_2 + 3H_2 \Longrightarrow 2NH_3 + 24.0 \text{ kcal}$$

The reaction is reversible, exothermic and formation of NH<sub>3</sub> is followed by a decrease in volume. According to Le Chatelier's principle, the optimum conditions for the greater yield of ammonia are:

- (a) **High pressure:** Usually a pressure of 200 atmospheres is applied.
- **(b) Low temperature:** The working temperature of 450-550°C is maintained, since reaction is very slow below this temperature.
- **(c) Catalyst:** At low temperature, although the yield of ammonia is more yet the reaction is very slow. In order to speed up the reaction, a catalyst is used. The following catalysts have been proposed for this purpose:
  - (i) Finely divided iron with some molybdenum as a promoter.
- (ii) Finely divided nickel and sodalime deposited over pumice stone.
  - (iii) Finely divided osmium or uranium.

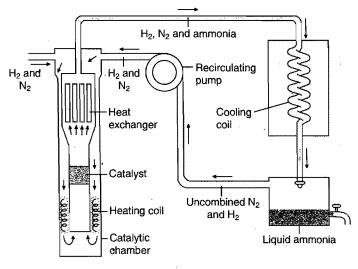

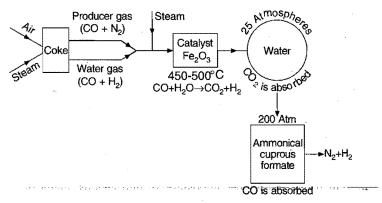

Fig. 10.3

Impure gases poison the catalyst; hydrogen and nitrogen used, therefore, be free from CO, etc., which can spoil the working of the catalyst.

Raw materials: Nitrogen and hydrogen are the chief raw materials. Nitrogen is obtained from air by liquefaction followed by fractional evaporation of liquid air. Hydrogen is obtained by electrolysis of water.

The gaseous mixture containing nitrogen and hydrogen is thoroughly dried before it is used for the formation of ammonia.

**Method:** The mixture of nitrogen and hydrogen in the ratio of 1:3 is compressed to 200 atmospheric pressure and allowed to enter the ammonia converter [Fig. 10.4 (a)] at the base.

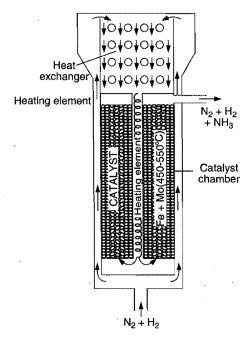

Fig. 10.4 (a) Ammonia converter

The gases are heated to 450-500°C. The gases now enter the catalyst chamber and interact forming ammonia. The issuing gases containing about 10% ammonia are cooled in water cooler when some ammonia liquefies. The remaining ammonia is removed from gaseous mixture by dissolving in water. The unreacted N<sub>2</sub> and H<sub>2</sub> are mixed with fresh gases and recirculated through the converter. A diagrammatic sketch of the plant is shown in Fig. 10.4 (b).

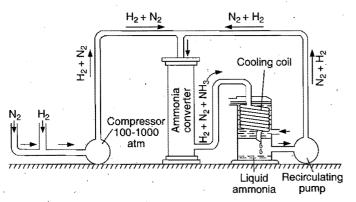

Fig. 10.4 (b)

 $CO_2$  absorbed in the water during the manufacture of  $N_2$  and  $H_2$  by Haber-Bosch process can be utilised for the manufacture of urea or ammonium sulphate from gypsum.

$$2NH_3 + CO_2 \xrightarrow{100\text{-}300 \quad atm.} NH_2COONH_4 \rightarrow NH_2CONH_2 + H_2O$$

$$\xrightarrow{Ammonium} \qquad Urea$$

$$carbamate$$

$$CaSO_4 + 2NH_4OH + CO_2 \longrightarrow (NH_4)_2SO_4 + CaCO_3 + H_2O$$

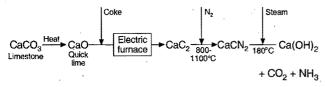

$$\xrightarrow{Ammonium} \qquad sulphate$$

#### (ii) Cyanamide process:

The calcium cyanamide is formed by the action of nitrogen on calcium carbide at 800-1100°C. It is then treated with superheated steam at 180°C under a pressure of 3 to 4 atmospheres when ammonia is produced.

$$CaCN_2 + 4H_2O \longrightarrow Ca(OH)_2 + CO_2 + 2NH_3$$

The flow sheet for this industry is given below:

Now-a-days low temperature (500-600°C) is used under 6-8 atmospheric pressure.

#### Physical properties:

- (i) Ammonia, NH<sub>3</sub>, is the most important commercial compound of nitrogen. It is a colourless gas with a characteristic irritating or pungent odour. It brings tears into the eyes.
  - (ii) It is lighter than air.
- (iii) It is highly soluble in water. One volume of water dissolves 1300 volumes of ammonia at 0°C and 1 atmosphere. The high solubility is due to the hydrogen bonding. The solubility of ammonia increases with increase of pressure and decreases with increase of temperature.

- (iv) It can be easily liquefied at room temperature by the application of pressure. The liquid ammonia is colourless and boils at -33°C. It freezes at -78°C. Liquid ammonia has a large heat of vaporisation (327 cal/g). It is, therefore, used in iceplants.
- (v) Ammonia molecules link together to form associated molecules through hydrogen bonding.

Higher melting point and boiling point in comparison to other hydrides of V group are due to hydrogen bonding.

#### Chemical properties:

(i) Stability: It is highly stable. It decomposes into nitrogen and hydrogen at red heat or when electric sparks are passed through it.

$$2NH_3 \rightleftharpoons N_2 + 3H_2$$

(ii) Combustion: Ordinary, ammonia is neither combustible nor a supporter of combustion. However, it burns in the presence of oxygen to form nitrogen and water.

$$4NH_3 + 3O_2 \longrightarrow 2N_2 + 6H_2O$$

(iii) Basic nature: Ammonia is a Lewis base, accepting proton to form ammonium ion as it has tendency to donate an electron pair.

It forms salts with acids.

$$\begin{array}{ccc} NH_3 + HCl & \longrightarrow & NH_4Cl^* \\ & \text{Ammonium chloride} \\ & \text{Thick white} \\ & \text{fumes} \end{array}$$
 
$$2NH_3 + H_2SO_4 & \longrightarrow & (NH_4)_2SO_4 \\ & \text{Ammonium sulphate} \end{array}$$

Ammonia dissolves in water, its solution in water is a weak base. The solution is described as aqueous ammonia. The reaction between ammonia and water produces relatively few ions; ammonia remains mostly in the molecular form. It's ionisation in water is represented as,

The relatively few ions present do not conduct electricity well and ammonia may thus be called a **weak base** or **weak electrolyte**.

The solution turns red litmus to blue and phenolphthalein pink.

(iv) Oxidation: It is oxidised to nitrogen when passed over heated CuO or PbO.

$$\begin{array}{l} 3\text{CuO} + 2\text{NH}_3 \longrightarrow 3\text{Cu} + \text{N}_2 + 3\text{H}_2\text{O} \\ 3\text{PbO} + 2\text{NH}_3 \longrightarrow 3\text{Pb} + \text{N}_2 + 3\text{H}_2\text{O} \end{array}$$

Both chlorine and bromine oxidise ammonia.

$$\begin{array}{c} 2NH_3 + 3Cl_2 \longrightarrow N_2 + 6HCl \\ 6NH_3 + 6HCl \longrightarrow 6NH_4Cl \\ \hline \\ 8NH_3 + 3Cl_2 \longrightarrow N_2 + 6NH_4Cl \\ (Excess) \end{array}$$

When chlorine is in excess an explosive substance nitrogen trichloride is formed.

$$NH_3 + 3Cl_2 \longrightarrow NCl_3 + 3HCl$$

Iodine flakes when rubbed with liquor ammonia form a dark brown precipitate of ammoniated nitrogen iodide which explodes readily on drying.

$$2NH_3 + 3I_2 \longrightarrow NH_3 \cdot NI_3 + 3HI$$

Hypochlorites and hypobromites oxidise ammonia to nitrogen.  $2NH_3 + 3NaClO \longrightarrow N_2 + 3NaCl + 3H_2O$ 

The oxidation of ammonia with bleaching powder occurs on warming.

$$3CaOCl_2 + 2NH_3 \longrightarrow 3CaCl_2 + N_2 + 3H_2O$$

Thus, ammonia acts as a reducing agent.

The restricted oxidation of  $NH_3$  can be done with air, when the mixture is passed over heated platinum gauze at 700-800°C.

$$4NH_3 + 5O_2 \xrightarrow{Pt} 4NO + 6H_2O$$

This is the Ostwald's process and used for the manufacture of HNO<sub>3</sub>.

(v) Formation of amides: When dry ammonia is passed over heated sodium or potassium, amides are formed with evolution of hydrogen.

$$2Na + 2NH_3 \longrightarrow 2NaNH_2 + H_2$$

(vi) Reactions of aqueous ammonia: Many metal hydroxides are formed which may be precipitated or remain dissolved in the form of complex compound in excess of  $NH_4OH$ .

$$FeCl_{3} + 3NH_{4}OH \longrightarrow Fe(OH)_{3} + 3NH_{4}Cl$$

$$ppt.$$

$$AlCl_{3} + 3NH_{4}OH \longrightarrow Al(OH)_{3} + 3NH_{4}Cl$$

$$ppt.$$

$$CrCl_{3} + 3NH_{4}OH \longrightarrow Cr(OH)_{3} + 3NH_{4}Cl$$

$$ppt.$$

$$CuSO_{4} + 2NH_{4}OH \longrightarrow Cu(OH)_{2} + (NH_{4})_{2}SO_{4}$$

$$Blue ppt.$$

$$\begin{array}{c} Cu(OH)_2 + (NH_4)_2SO_4 + 2NH_4OH \rightarrow [Cu(NH_3)_4]SO_4 + 4H_2O \\ & \text{Tetramine copper} \\ & \text{sulphate} \\ & \text{(Deep blue soln.)} \end{array}$$

$$\begin{array}{c} CdSO_4 + 4NH_4OH \longrightarrow [Cd(NH_3)_4]SO_4 + 4H_2O \\ \hline Cadmium \ tetramine \\ sulphate \\ (Colourless \ soln.) \end{array}$$

$$\begin{array}{c} AgNO_3 + NH_4OH \longrightarrow AgOH + NH_4NO_3 \\ & \text{White ppt.} \end{array}$$

$$AgOH + 2NH_4OH \longrightarrow [Ag(NH_3)_2]OH + 2H_2O$$
  
Soluble

AgCl also dissolves in NH<sub>4</sub>OH solution.

$$AgCl + 2NH_4OH \longrightarrow [Ag(NH_3)_2]Cl + 2H_2O$$
Diamine silver chloride
$$ZnSO_4 + 2NH_4OH \longrightarrow Zn(OH)_2 + (NH_4)_2SO_4$$

$$ZnSO_4 + 2NH_4OH \longrightarrow Zn(OH)_2 + (NH_4)_2SO_4$$

$$Zn(OH)_2 + (NH_4)_2SO_4 + 2NH_4OH \longrightarrow$$

 $[Zn(NH_3)_4]SO_4 + 4H_2O$ Tetramine zinc sulphate

(Soluble) Colourless

Nickel salt first gives a green precipitate which dissolves in excess of NH<sub>4</sub>OH.

$$NiCl_2 + 2NH_4OH \longrightarrow Ni(OH)_2 + 2NH_4Cl$$

$$Ni(OH)_2 + 2NH_4Cl + 4NH_4OH \longrightarrow [Ni(NH_3)_6]Cl_2 + 6H_2O$$

It forms a white precipitate with mercuric chloride.

$$\begin{array}{c} HgCl_2 + 2NH_4OH \longrightarrow HgNH_2Cl + NH_4Cl + 2H_2O \\ \text{Amido mercuric} \\ \text{chloride} \end{array}$$

It forms a grey precipitate with mercurous chloride.

$$Hg_2Cl_2 + 2NH_4OH \longrightarrow \underbrace{Hg + HgNH_2Cl}_{Grev} + NH_4Cl + 2H_2O$$

**(vii) Reaction with Nessler's reagent:** A reddish brown ppt. is formed.

$$2KI + HgCl_2 \longrightarrow HgI_2 + 2KCl$$

$$2KI + HgI_2 \longrightarrow K_2HgI_4$$

Alkaline solution of K<sub>2</sub>HgI<sub>4</sub> is called Nessler's reagent. This gives brown ppt. with NH<sub>3</sub> called iodide of Millon's base.

$$2K_2HgI_4 + NH_3 + 3KOH \longrightarrow H_2NHgOHgI + 7KI + 2H_2O$$
Brown ppt.

(viii) Reaction with  $CO_2$ : When gaseous  $CO_2$  is reacted with liquid  $NH_3$  at 453-473 K under pressure of 220 atmospheres, it first forms ammonium carbamate which decomposes to give urea.

$$2NH_3 + CO_2 \longrightarrow NH_2COONH_4 \longrightarrow NH_2CONH_2 + H_2O$$
Ammonium carbamate Urea

(ix) Reaction with sodium hypochlorite: When a strong aqueous solution of ammonia is boiled with sodium hypochlorite in presence of glue, hydrazine is formed.

$$NH_3 + NaOCl \longrightarrow NH_2Cl + NaOH$$
  
 $NH_2Cl + NH_3 \longrightarrow NH_2 \cdot NH_2 + HCl$   
Chloramine Hydrazine

Hydrazine produced may be decomposed by chloramine into  $N_2$ .

$$2NH_2Cl + NH_2 \cdot NH_2 \longrightarrow N_2 + 2NH_4Cl$$

(x) Liquid ammonia as a solvent: Ammonia like water undergoes self ionisation in liquid state.

$$2NH_3 \Longrightarrow NH_4^+ + NH_2^-$$
$$2H_2O \Longrightarrow H_3O^+ + OH^-$$

Liquid ammonia is, thus, used for carrying out many reactions of polar compounds in non-aqueous medium.

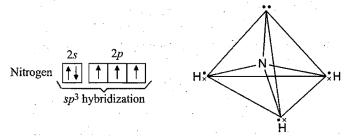

#### Uses:

- (i) Liquid ammonia is used in refrigeration on account of its large heat of evaporation.
  - (ii) Ammonia is used for making artificial silk.
- (iii) Ammonia is also the starting compound for the preparation of most of the other nitrogen compounds. Ammonia is used for the manufacture of nitric acid (Ostwald's process), sodium bicarbonate (Solvay process) and ammonium compounds. Ammonium sulphate, ammonium calcium phosphate, ammonium calcium nitrate, etc., are used as fertilizers. Ammonium nitrate is used in certain explosives. Ammonia is also used in the manufacture of urea, NH<sub>2</sub>CONH<sub>2</sub> which is an excellent fertilizer of nitrogen and is used in the manufacture of urea-formaldehyde plastics.
- (iv) Ammonia is used in the form of ammonium hydroxide (aq. solution) in the laboratory in qualitative and quantitative analysis.
- (v) Liquid hydrogen is not safe to transport in cylinders. Ammonia can be easily liquefied and transported safely in cylinders. Ammonia can be decomposed into hydrogen and nitrogen by passing over heated metallic catalysts. Thus, ammonia is the source for the production of hydrogen at any destination.
- (vi) It is used as a cleansing agent for removing grease.
   Tests of ammonia: (i) It is identified by its characteristic odour.
- (ii) It turns moist red litmus paper blue and moist turmeric paper brown.
- (iii) With a drop of HCl, it forms thick white fumes of ammonium chloride.
- (iv) With Nessler's reagent, it forms a reddish brown precipitate or colouration.
- (v) Ammonia gas when passed through copper sulphate solution gives a deep blue colour.
  - (vi) It gives a yellow precipitate with chloroplatinic acid.

$$\begin{array}{ccc} 2NH_3 \, + \, H_2PtCl_6 & \longrightarrow & (NH_4)_2PtCl_6 \\ & & \text{Ammonium } & \text{chloroplatinate} \\ & & & (Yellow) \end{array}$$

**Structure:** Ammonia is a covalent molecule. Three hydrogen atoms are linked to nitrogen by single covalent bonds. Its simple electronic structure may be represented as:

The formation of ammonia molecule involves sp<sup>3</sup> hybridization of nitrogen atom giving rise to four hybrid orbitals directed towards the four corners of a tetrahedron.

Three hybrid orbitals having single electron each form sigma bonds with three hydrogen atoms and the fourth hybrid orbital contains one pair of electrons. On account of the presence of this lone pair of electrons, the molecule gets distorted and acquires a *pyramidal structure*. The bond angle

N is not 
$$109^{\circ}28'$$
 but it is about  $107.5^{\circ}$ .

#### Ammonium compounds

The compounds having NH<sub>4</sub><sup>+</sup> ions are called ammonium compounds. Some of the general characteristics of these compounds are described below:

(a) These are generally white crystalline solids, dissolve in water and are strong electrolytes. Salts of strong acids give acidic solutions.

$$NH_{4}CI + H_{2}O \Longrightarrow NH_{4}OH + HCI$$

- (b) They resemble the salts of potassium and rubidium in solubility and structure since the three ions are of comparable radii :  $NH_4^+ = 148 \text{ pm}$ ,  $K^+ = 133 \text{ pm}$ ,  $Rb^+ = 148 \text{ pm}$ .
  - (c) When heated with alkali, they evolve ammonia.

$$NH_4Cl + NaOH \longrightarrow NH_3 + NaCl + H_2O$$
or
$$NH_4^+ + OH^- \longrightarrow NH_3 + H_2O$$

- (d) Ammonium compounds with Nessler's reagent give a reddish brown precipitate or colouration.
- (e) Many ammonium compounds volatilise with dissociation around 300°C. For example,

$$NH_4Cl(s) \longrightarrow NH_3(g) + HCl(g)$$
  
 $NH_4NO_3(s) \longrightarrow NH_3(g) + HNO_3(g)$ 

(f) Salts that contain oxidising anion first decompose giving NH<sub>3</sub> and then NH<sub>3</sub> is oxidised to N<sub>2</sub> or N<sub>2</sub>O or both on heating.

$$(NH_4)_2Cr_2O_7 \longrightarrow N_2 + Cr_2O_3 + 4H_2O$$

$$NH_4NO_2 \longrightarrow N_2 + 2H_2O$$

$$NH_4NO_3 \longrightarrow N_2O + 2H_2O$$

[Note: The reaction of ammonium dichromate is often referred to as the "Volcano" reaction. A source of heat, such as lighted match, will cause the orange crystals to decompose, producing sparks and a large volume of dark green chromic oxide, Cr<sub>2</sub>O<sub>3</sub>. This reaction should not be carried in open.]

#### Some of the important ammonium compounds are:

(i) Ammonium hydroxide, NH<sub>4</sub>OH: It is the aqueous solution of ammonia and behaves as a weak base.

$$NH_3 + H_2O \Longrightarrow NH_4OH \Longrightarrow NH_4^+ + OH^-$$

(ii) Ammonium chloride, NH<sub>4</sub>Cl: This ammonium compound is also known as salammoniac. It is obtained by reacting NH<sub>3</sub> with HCl.

It is a white crystalline solid, highly soluble in water. It is a volatile salt and decomposes at high temperatures into ammonia and hydrochloric acid gas. These two gases again combine on cooling.

$$NH_4CI \Longrightarrow NH_3 + HCI$$

The main uses of ammonium chloride are in soldering and tinning, in making of dry cells, in dyeing and calicoprinting and in medicine. It is also used as a laboratory reagent.

(iii) Ammonium sulphate, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>: It is known in India as sindri fertilizer. It can be obtained by absorbing NH<sub>3</sub> in 60% H<sub>2</sub>SO<sub>4</sub>.

$$2NH_3 + H_2SO_4 \longrightarrow (NH_4)_2SO_4$$

It is a colourless crystalline solid and highly soluble in water. It is used as a nitrogen fertilizer and a reagent in the laboratory.

(iv) Ammonium nitrate, NH<sub>4</sub>NO<sub>3</sub>: It is prepared by passing ammonia gas in 60% nitric acid.

$$NH_3 + HNO_3 \longrightarrow NH_4NO_3$$

It is a colourless, deliquescent solid. It is very soluble in water. On gentle heating it decomposes and evolves nitrous oxide.

$$NH_4NO_3 \longrightarrow N_2O + 2H_2O$$

This is an explosive solid. On rapid heating it explodes.

$$2NH_4NO_3 \longrightarrow 2N_2 + O_2 + 4H_2O$$

It is mainly used for making explosives such as amatol and ammonal.

**Amatol:**  $80\%NH_4NO_3 + 20\% T.N.T.$ 

**Ammonal:**  $NH_4NO_3 + Al$  powder (small quantity)

It is also used as a fertilizer. For this purpose, it is mixed with other substances, e.g.,

Leuna saltpetre  $NH_4NO_3 + (NH_4)_2SO_4$ 

Nitro chalk NH<sub>4</sub>NO<sub>3</sub> + CaCO<sub>3</sub>

#### 2. Hydrazine or Diamide, NH<sub>2</sub>·NH<sub>2</sub> or N<sub>2</sub>H<sub>4</sub>

This is another hydride of nitrogen. It is prepared by following methods:

(i) Raschig's method: A strong aqueous solution of ammonia is boiled with sodium hypochlorite in presence of a little glue.

$$NH_3 + NaOCl \longrightarrow NH_2Cl + NaOH$$
 $NH_2Cl + NH_3 \longrightarrow NH_2\cdot NH_2 + HCl$ 
Chloramine Hydrazine

 $2NH_3 + NaOCl \longrightarrow NH_2 \cdot NH_2 + NaCl + H_2O$ 

[Hydrazine produced may be decomposed by chloramine to  $N_2$ .

$$2NH_2Cl + N_2H_4 \longrightarrow 2NH_4Cl + N_2$$

The function of glue is to prevent this reaction. The yield is about 60-70%.]

Recovery of hydrazine from the above solution is made in the following manner:

$$\begin{array}{c} \text{Solution} \xrightarrow{H_2SO_4} N_2H_5 \cdot \text{HSO}_4 \xrightarrow{NaOH} N_2H_4 \cdot H_2O \xrightarrow{Distilled} \\ \text{Sparingly soluble} & \text{Hydrazine} \\ \text{hydrate} \end{array}$$

NH<sub>2</sub>·NH<sub>2</sub> Hydrazine

(ii) Hydrazine may also be obtained by treating a solution of K<sub>2</sub>SO<sub>3</sub> saturated with NO with sodium amalgam (reduction of NO).

$$K_2SO_3\cdot N_2O_2 + 6H \longrightarrow K_2SO_4 + N_2H_4 + H_2O$$

Recovery is made from the solution as described above. It is a colourless furning liquid. It is miscible with water in all proportions. It is soluble in alcohol.

It acts as diacid base. Thus, it forms two series of salts.

NH<sub>2</sub>·NH<sub>3</sub>Cl ClH<sub>3</sub>N·NH<sub>3</sub>Cl Hydrazine Hydrazine monochloride dichloride

It burns in air liberating huge amount of energy. The alkyl derivatives of hydrazine are used these days as potential rocket fuels. It reacts with nitrous acid to give hydrazoic acid, N<sub>3</sub>H.

$$N_2H_4 + HNO_2 \longrightarrow N_3H + 2H_2O$$

Hydrazine and its salts act as powerful reducing agents.

$$\begin{array}{c} \text{PtCl}_4 + \text{N}_2\text{H}_4 \longrightarrow \text{Pt} + \text{N}_2 + 4\text{HCl} \\ 4\text{AgNO}_3 + \text{N}_2\text{H}_4 \longrightarrow 4\text{Ag} + \text{N}_2 + 4\text{HNO}_3 \\ 4\text{AuCl}_3 + 3\text{N}_2\text{H}_4 \longrightarrow 4\text{Au} + 3\text{N}_2 + 12\text{HCl} \end{array}$$

It reduces Fehling's solution to red cuprous oxide, iodates to iodides and decolourises acidified KMnO<sub>4</sub> solution. It is used as a fuel for rockets, reducing agent and a reagent in organic chemistry.

Structure  $N = \frac{110^{\circ}}{1.47\text{\AA}} \text{N} = 110^{\circ}$ 

#### ■ 3. Hydrazoic Acid, N<sub>3</sub>H

It is the third hydride of nitrogen. It is an acid while other hydrides, NH<sub>3</sub> and N<sub>2</sub>H<sub>4</sub> are bases. It is prepared by the action of nitrous acid on hydrazine.

$$NH_2 \cdot NH_2 + HNO_2 \longrightarrow N_3H + 2H_2O$$

It is also formed in the form of sodium salt by passing nitrous oxide on sodamide.

Pure hydrazoic acid is a colourless liquid. It is volatile and has very bad odour. It is poisonous in nature. It explodes violently when struck or heated. It is soluble in water and alcohol. It is slightly stronger acid. It dissolves many metals forming azides.

$$2N_3H + Mg \longrightarrow Mg(N_3)_2 + H_2$$

Silver, lead and mercurous azides are formed by reacting their soluble salts with N<sub>3</sub>H.

$$AgNO_3 + N_3H \longrightarrow AgN_3 + HNO_3$$

These azides explode violently when struck (used as detonators).

It reduces acidified KMnO<sub>4</sub>, nitrous acid, etc.

$$2N_3H + O \longrightarrow 3N_2 + H_2O$$
  
 $N_3H + HNO_2 \longrightarrow N_2 + N_2O + H_2O$ 

It oxidises HCl into Cl<sub>2</sub>.

$$N_3H + 2HCl \longrightarrow N_2 + NH_3 + Cl_2$$

Hydrazoic acid is a resonance hybrid.

$$\mathbf{H} - \mathbf{N} = \mathbf{N} = \mathbf{N} : \longleftrightarrow \mathbf{H} - \mathbf{N} : \longrightarrow \mathbf{N} = \mathbf{N}$$

#### 4. Oxides of Nitrogen

Nitrogen forms a number of oxides. The well known oxides of nitrogen are:

(i) Nitrous oxide,  $N_2O$ , (ii) Nitric oxide, NO, (iii) Nitrogen trioxide,  $N_2O_3$ , (iv) Nitrogen dioxide or Dinitrogen tetroxide,  $NO_2$  or  $N_2O_4$  and (v) Nitrogen pentoxide,  $N_2O_5$ . Nitrous oxide is nontoxic in small amounts but all the other nitrogen oxides are highly toxic.

# (I) Dinitrogen Oxide or Nitrous Oxide, N<sub>2</sub>O or Laughing Gas (Oxidation number +1)

**Preparation:** It can be prepared by heating ammonium nitrate or a mixture of sodium nitrate and ammonium sulphate.

$$NH_4NO_3 \longrightarrow N_2O + 2H_2O$$

$$2NaNO_3 + (NH_4)_2SO_4 \longrightarrow 2NH_4NO_3 + Na_2SO_4$$

$$\downarrow \qquad \qquad \downarrow$$

$$2N_2O + 4H_2O$$

The mixture consists of three parts ammonium sulphate and four parts sodium nitrate. It is heated carefully below 240°C. The evolved gas is collected over hot water as it is fairly soluble in cold water. It is usually contaminated with nitric oxide (NO), ammonia (NH<sub>3</sub>) and water vapour. The gas is passed through ferrous sulphate solution to remove nitric oxide and through concentrated sulphuric acid to remove ammonia and water vapour.

$$\begin{array}{cccc} FeSO_4 + NO & \longrightarrow & FeSO_4 \cdot NO \\ & & Addition \ product \\ H_2SO_4 + 2NH_3 & \longrightarrow & (NH_4)_2SO_4 \\ & & & Ammonium \ sulphate \\ \end{array}$$

The following reactions can also be used to prepare nitrous oxide.

(a) By the action of cold and dilute nitric acid on zinc metal.

$$4Zn + 10HNO_3 \longrightarrow 4Zn(NO_3)_2 + N_2O + 5H_2O$$

(b) By reducing nitric acid with stannous chloride and hydrochloric acid.

$$4SnCl_2 + 8HCl + 2HNO_3 \longrightarrow 4SnCl_4 + N_2O + 5H_2O$$

(c) By reducing nitric oxide with sulphur dioxide.

$$2NO + SO_2 + H_2O \longrightarrow H_2SO_4 + N_2O$$

(d) By heating the mixture of hydroxylamine hydrochloride and sodium nitrite (1 : 1).

$$NH_2OH \cdot HCl + NaNO_2 \longrightarrow N_2O + NaCl + 2H_2O$$

**Properties:** (a) It is a colourless, tasteless gas with a pleasant and sweet odour.

- (b) When inhaled in moderate quantity, it produces hysterical laughter, hence named as **laughing gas.** However, when inhaled for long, it produces insensibility and may prove fatal too.
  - (c) It is heavier than air.
- (d) It is fairly soluble in cold water but not in hot water. It dissolves readily in fats and is tasteless and nontoxic in small amounts.

The solution in water is neutral in nature. This is probably due to the following equilibrium which lies in the left hand side.

$$N_2O + H_2O \Longrightarrow H_2N_2O_2 + H_2O \Longrightarrow H_2O_2 + H_2O_2 +$$

The oxide may be taken as an anhydride of hyponitrous acid. However, the acid is not obtained by dissolving  $N_2O$  in water.

- (e) It is neutral to litmus.
- (f) It does not burn but supports combustion. The burning material decomposes nitrous oxide into nitrogen and oxygen. The oxygen then helps in the burning.

$$2N_2O \xrightarrow{520-900^{\circ}C} 2N_2 + O_2$$

It supports combustion of sulphur, phosphorus, magnesium, sodium, candle and a splinter.

$$S + 2N_2O \longrightarrow SO_2 + 2N_2$$

$$4P + 10N_2O \longrightarrow 2P_2O_5 + 10N_2$$

$$Mg + N_2O \longrightarrow MgO + N_2$$

$$2Na + N_2O \longrightarrow Na_2O + N_2$$

(g) It is decomposed by red hot copper.

$$Cu + N_2O \longrightarrow CuO + N_2$$

(h) A mixture of hydrogen and nitrous oxide (equal volumes) explodes with violence.

$$N_2O + H_2 \longrightarrow N_2 + H_2O$$

(i) It forms sodium azide on reaction with NaNH<sub>2</sub> (sodamide).

$$NaNH_2 + N_2O \longrightarrow NaN_3 + H_2O$$
  
 $NaNH_2 + H_2O \longrightarrow NaOH + NH_3$ 

$$\frac{}{2\text{NaNH}_2 + \text{N}_2\text{O} \longrightarrow \text{NaN}_3 + \text{NaOH} + \text{NH}_3}$$

Uses: (i) A mixture of nitrous oxide and oxygen is used as an dental anaesthetic and other minor surgical operations.

(ii) It is sometime used as a foaming agent and as a propellant gas for whipped-cream dispensers. The gas dissolves in cream under pressure. When the cream is dispersed, the gas bubbles out, forming a foam.

**Structure:** N<sub>2</sub>O is linear and unsymmetrical molecule. It is considered as a resonance hybrid of the following two structures:

$$: \stackrel{\cdot}{N} \xrightarrow{\sigma} \stackrel{+}{N} \xrightarrow{\sigma} \stackrel{\cdot}{O} : \longleftrightarrow : \stackrel{\cdot}{N} \xrightarrow{\frac{\sigma}{2\pi}} \stackrel{+}{N} \xrightarrow{\sigma} \stackrel{\cdot}{O} :$$

The bond length between N-N is 113 pm and between N-O is 119 pm.

It has a very small value of dipole moment (0.116 D).

Tests: (i) It is a gas with pleasant odour.

- (ii) It supports the combustion of glowing splinter.
- (iii) It does not form brown fumes with nitric oxide.

#### (II) Nitric Oxide, NO

(Oxidation number +2)

Preparation: (a) By the action of dilute nitric acid on copper (Lab. method).

Copper chips are taken in a Woulfe-bottle and some water is added. Concentrated nitric acid is poured through the thistle funnel and the nitric oxide liberated is collected over water.

$$3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$$

The liberated gas may contain NO<sub>2</sub> and N<sub>2</sub>O. These are separated by passing the mixture through ferrous sulphate solution. NO forms a dark brown nitroso-ferrous sulphate. When this solution is heated, pure nitric oxide is liberated.

$$FeSO_4 + NO \xrightarrow{\text{(Impure gas)}} FeSO_4 \cdot NO \xrightarrow{\text{Heat}} FeSO_4 + NO \xrightarrow{\text{(Pure gas)}}$$

(b) A pure sample of nitric oxide is obtained when a mixture of KNO<sub>3</sub>, FeSO<sub>4</sub> and dilute H<sub>2</sub>SO<sub>4</sub> is heated. This is also a laboratory method.

$$2KNO_3 + H_2SO_4 \longrightarrow K_2SO_4 + 2HNO_3$$

$$2HNO_3 \longrightarrow H_2O + 2NO + 3O$$

$$[2FeSO_4 + H_2SO_4 + O \longrightarrow Fe_2(SO_4)_3 + H_2O] \times 3$$

 $2KNO_3+6FeSO_4+4H_2SO_4 \rightarrow K_2SO_4+3Fe_2(SO_4)_3+2NO+4H_2O$ 

- (c) Nitric oxide is the first product obtained from the following two processes during the manufacture of nitric acid.
- (i) Electric arc process: By passing air through an electric arc, nitrogen and oxygen of the air combine together to form nitric oxide.

$$N_2 + O_2 \stackrel{\text{Electric arc}}{\longleftarrow} 2NO$$

(ii) Ostwald's process: By restricted oxidation of ammonia with air in presence of platinum gauze catalyst at 750°C, nitric oxide is formed.

$$4NH_3 + 5O_2 \xrightarrow{Pt. \text{ gauze}} 4NO + 6H_2O$$

Properties: (a) It is a colourless gas, slightly heavier than air.

- (b) It is sparingly soluble in water.
- (c) It is liquefied with difficulty under high pressure and low temperature (-151°C).
- (d) It is paramagnetic indicating the presence of unpaired electron in the molecule.
  - (e) It is neutral to litmus.
- (f) It at once reacts with oxygen to give brown fumes of nitrogen dioxide.

$$2NO + O_2 \longrightarrow 2NO_2$$

(g) It is stable oxide. It decomposes into nitrogen and oxygenwhen heated at 800°C.

$$2NO \xrightarrow{800^{\circ}C} N_2 + O_2$$

(h) It is combustible and supports combustion of boiling sulphur and burning phosphorus.

$$S + 2NO \longrightarrow SO_2 + N_2$$

(i) It dissolves in cold ferrous sulphate solution by forming a hydrated nitrosyl complex.

In the complex [Fe(H<sub>2</sub>O)<sub>5</sub>NO]SO<sub>4</sub>, iron is assumed to exhibit Fe<sup>2+</sup> state, but from magnetic moment measurements it is observed that iron exhibits +1 oxidation state instead of +2. In this complex, 'NO' exhibits +1 oxidation state.

(j) It is oxidised to nitric acid by oxidising agents like acidified KMnO<sub>4</sub> or hypochlorous acid. Thus, it acts as a reducing agent.

$$[2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O] \times 3$$

$$[NO + O \longrightarrow NO_2] \times 15$$

$$[3NO_2 + H_2O \longrightarrow 2HNO_3 + NO] \times 5$$

$$6KMnO_4 + 9H_2SO_4 + 10NO \longrightarrow 3K_2SO_4 + 6MnSO_4 + 10HNO_3 + 4H_2O$$

$$[\text{HCIO} \longrightarrow \text{HCI} + \text{O}] \times 3$$

$$[\text{NO} + \text{O} \longrightarrow \text{NO}_2] \times 3$$

$$3\text{NO}_2 + \text{H}_2\text{O} \longrightarrow 2\text{HNO}_3 + \text{NO}$$

$$3HClO + 2NO + H_2O \longrightarrow 2HNO_3 + 3HCl$$
  
 $HNO_3$  oxidises nitric oxide into  $NO_2$ .

$$2HNO_3 + NO \longrightarrow H_2O + 3NO_2$$

(k) It acts as an oxidising agent. It oxidises  $SO_2$  to  $H_2SO_4$  and  $H_2S$  to S.

$$SO_2 + 2NO + H_2O \longrightarrow H_2SO_4 + N_2O$$
  
 $H_2S + 2NO \longrightarrow H_2O + S + N_2O$ 

When exploded with hydrogen, it liberates nitrogen.

$$2H_2 + 2NO \longrightarrow 2H_2O + N_2$$

However, when a mixture of hydrogen and nitric oxide is passed over platinum black, ammonia is formed.

$$2NO + 5H_2 \longrightarrow 2NH_3 + 2H_2O$$

Stannous chloride reduces nitric oxide to hydroxylamine.

$$[SnCl2 + 2HCl \longrightarrow SnCl4 + 2H] \times 3$$

$$2NO + 6H \longrightarrow 2NH2OH$$

$$3\text{SnCl}_2 + 6\text{HCl} + 2\text{NO} \longrightarrow 3\text{SnCl}_4 + 2\text{NH}_2\text{OH}$$

(l) Nitric oxide directly combines with halogens (fluorine, chlorine, bromine) to form corresponding nitrosyl halides.

2NO + 
$$X_2 \longrightarrow 2NOX$$
  
(F<sub>2</sub>, Cl<sub>2</sub> or Br<sub>2</sub>) Nitrosyl halide

Uses: (i) In the manufacture of nitric acid.

- (ii) As a catalyst in lead chamber process for the manufacture of sulphuric acid.
- (iii) In the detection of oxygen to distinguish it from nitrous oxide.

**Structure:** The molecule NO has eleven valency electrons and it is impossible for all of them to be paired. Hence, the molecule contains an odd electron which makes the gaseous nitric oxide as paramagnetic.

The structure is represented as a resonance hybrid.

$$: \overset{\scriptscriptstyle +}{N} = \overset{\scriptstyle -}{0} : \overset{\scriptstyle -}{\longleftrightarrow} : \overset{\scriptstyle -}{N} = \overset{\scriptstyle -}{0} : \overset{\scriptstyle -}{\longleftrightarrow} : \overset{\scriptstyle -}{N} = \overset{\scriptstyle -}{0} :$$

In the liquid and solid states, NO is known to form a loose dimer,  $N_2O_2$ . In this form, it is diamagnetic.

Note: The electron configuration of NO is:

$$KK(\sigma^2 s)^2 (\sigma^2 s)^2 (\sigma^2 p_z)^2 (\pi^2 p_x)^2 (\pi^2 p_x)^4 (\pi^2 p_x)^4$$

The  $\overset{*}{\pi}$  electron is lost easily to give nitrosonium ion, NO<sup>+</sup> which forms many salts. NO<sup>+</sup> can be obtained by reacting N<sub>2</sub>O<sub>3</sub> with H<sub>2</sub>SO<sub>4</sub>.

$$N_2O_3 + 3H_2SO_4 \longrightarrow 2NO^+ + 3HSO_4^- + H_3O^+$$
  
From solution, NOHSO<sub>4</sub> is isolated.

# (III) Dinitrogen Trioxide, N<sub>2</sub>O<sub>3</sub> (Oxidation number +3)

This oxide is also called **nitrogen sesquioxide** or **nitrous** anhydride.

**Preparation:** It is obtained by the reduction of nitric acid with arsenious oxide.

$$2HNO_3 \longrightarrow H_2O + N_2O_3 + 2O$$

$$As_2O_3 + 2O \longrightarrow As_2O_5$$

$$As_2O_5 + 3H_2O \longrightarrow 2H_3AsO_4$$

$$As_2O_3 + 2HNO_3 + 2H_2O \longrightarrow 2H_3AsO_4 + N_2O_3$$

It is known in pure state in solid form at very low temperature. In the vapour state, it is present as an equimolecular mixture of NO and NO<sub>2</sub>. The mixture of NO and NO<sub>2</sub> may be obtained by the action of 6N nitric acid on copper.

$$2\text{Cu} + 6\text{HNO}_3 \longrightarrow 2\text{Cu}(\text{NO}_3)_2 + \underbrace{\text{NO} + \text{NO}_2}_{\text{N}_2\text{O}_3} + 3\text{H}_2\text{O}$$

**Properties:** (a) It condenses to a blue coloured liquid at -30°C. The liquid when warmed at room temperature, decomposes to a mixture of NO and NO<sub>2</sub> (brown coloured).

$$\begin{array}{c} N_2O_3 \\ \text{Blue coloured liquid} \end{array} \xrightarrow{\text{Room temp.}} \underbrace{\begin{array}{c} NO+NO_2 \\ \text{Brown coloured gas} \end{array} }_{\text{Brown coloured gas}}$$

(b) It is an acidic oxide. It forms nitrous acid with water and hence the name nitrous anhydride.

$$N_2O_3 + H_2O \longrightarrow 2HNO_2$$

The oxide combines with caustic alkali forming corresponding nitrite.

$$2NaOH + N_2O_3 \longrightarrow 2NaNO_2 + H_2O$$

**Structure:** Since the oxide is unstable in liquid and gaseous states and decomposes into NO and NO<sub>2</sub>, it may be assumed that it has the following electronic structure:

$$: O: \stackrel{\times}{\times} \stackrel{\times}{N} \times : O: \stackrel{\times}{\times} \stackrel{\times}{\times} : O:$$
 or  $O=N-O-N=O$ 

The structure is supported by its diamagnetic behaviour. Structure of  $N_2O_3$  is of two forms:

# (IV) Nitrogen Dioxide, NO<sub>2</sub> or Dinitrogen Tetroxide, N<sub>2</sub>O<sub>4</sub> (Oxidation number +4)

This oxide exists as  $NO_2$  in gaseous state while at low temperature, it exists as a dimer  $N_2O_4$  (solid state).

$$\begin{array}{ccc} 2NO_2 & \xrightarrow{-11^{\circ}C} & N_2O_4 \\ \text{Brown gas} & & \text{Colourless solid} \end{array}$$

**Preparation:** It is prepared in the laboratory either by heating nitrates of heavy metals or by the action of concentrated nitric acid on metals like copper, silver, lead, etc.

$$2Pb(NO_3)_2 \longrightarrow 2PbO + 4NO_2 + O_2$$

The mixture of nitrogen dioxide and oxygen is passed through a U-tube cooled by freezing mixture. Nitrogen

dioxide condenses to a pale yellow liquid while oxygen escapes.

Cu + 4HNO<sub>3</sub>  $\longrightarrow$  Cu(NO<sub>3</sub>)<sub>2</sub> + 2NO<sub>2</sub> + 2H<sub>2</sub>O It is also obtained by air oxidation of nitric oxide.

$$2NO + O_2 \longrightarrow 2NO_2$$

**Properties:** (a) It is a brown coloured gas with pungent odour. Above 140°C, it is 100% NO<sub>2</sub>. The liquid as well as solid is entirely  $N_2O_4$  (dimer) at low temperature. The liquid boils at 22°C and solid melts at -11°C.

(b) It decomposes completely into nitric oxide and oxygen at 620°C.

$$2NO_2 \xrightarrow{620^{\circ}C} \underbrace{2NO + O_2}_{Gaseous \ mixture}$$

$$\underbrace{Colourless}_{(Colourless)}$$

(c) When reacted with cold water, it forms a mixture of nitrous acid and nitric acid.

$$2NO_2 + H_2O \longrightarrow HNO_2 + HNO_3$$

On account of this, it is known as **mixed anhydride** of these two acids. However, with an excess of warm water it forms nitric acid and nitric oxide.

$$3NO_2 + H_2O \longrightarrow 2HNO_3 + NO$$

(d) When absorbed by alkalies, nitrites and nitrates are formed.

$$2NO_2 + 2NaOH \longrightarrow NaNO_2 + NaNO_3 + H_2O$$

(e) It acts as an oxidising agent. It oxidises metals like sodium, potassium, mercury, tin, copper, etc.

$$NO_2 + 2Na \longrightarrow Na_2O + NO$$
  
 $NO_2 + 2Cu \longrightarrow Cu_2O + NO$ 

Non-metals like carbon, sulphur, phosphorus when burnt in its atmosphere, are converted into corresponding oxides.

$$5NO_2 + 2P \longrightarrow P_2O_5 + 5NO$$
  
 $2NO_2 + S \longrightarrow SO_2 + 2NO$   
 $2NO_2 + C \longrightarrow CO_2 + 2NO$ 

It liberates iodine from KI and turns starch-iodide paper blue.

$$2KI + 2NO_2 \longrightarrow 2KNO_2 + I_2$$

In aqueous solution, it oxidises SO<sub>2</sub> to sulphuric acid.

$$SO_2 + H_2O + NO_2 \longrightarrow H_2SO_4 + NO$$

This reaction is used for the manufacture of H<sub>2</sub>SO<sub>4</sub> by lead chamber process.

H<sub>2</sub>S is oxidised to S and CO to CO<sub>2</sub>.

$$H_2S + NO_2 \longrightarrow H_2O + S + NO$$
  
 $CO + NO_2 \longrightarrow CO_2 + NO$ 

(f) It behaves also as a reducing agent. It reduces ozone to oxygen.

$$2NO_2 + O_3 \longrightarrow N_2O_5 + O_2$$

It decolourises acidified KMnO<sub>4</sub> solution.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O$$
  
 $10NO_2 + 5H_2O + 5O \longrightarrow 10HNO_3$ 

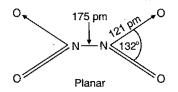

$$2KMnO_4 + 3H_2SO_4 + 10NO_2 + 2H_2O \longrightarrow K_2SO_4 + 2MnSO_4 + 10HNO_3$$

**Uses:** (i) It is used for the manufacture of nitric acid. (ii) It is employed as a catalyst in the lead chamber process for the manufacture of sulphuric acid.

**Structure:** NO<sub>2</sub> molecule has V-shaped structure with O—N—O bond angle 132° and N—O bond length of about 119 pm which is intermediate between a single and a double bond. Hence, NO<sub>2</sub> is regarded as a resonance hybrid of the following two structures:

The molecule is an odd electron molecule. The paramagnetic behaviour of  $NO_2$  confirms this view. Due to possession of odd electron, it is coloured and has a tendency to polymerise to form a colourless dimer,  $N_2O_4$ . The dimer is planar in structure with N—N bond length 175 pm.

# (V) Dinitrogen or Nitrogen Pentoxide, N<sub>2</sub>O<sub>5</sub> (oxidation number +5)

This oxide is also known as nitric anhydride.

**Preparation:** It is prepared by distilling concentrated nitric acid with phosphorus pentoxide in a glass apparatus.

$$2HNO_3 \longrightarrow H_2O + N_2O_5$$

$$P_2O_5 + H_2O \longrightarrow 2HPO_3$$

$$P_2O_5 + 2HNO_3 \longrightarrow 2HPO_3 + N_2O_5$$

It is also prepared by the action of dry chlorine on solid silver nitrate at 95°C.

$$4AgNO_3 + 2Cl_2 \longrightarrow 4AgCl + 2N_2O_5 + O_2$$

**Properties:** (a) It is a white crystalline solid. The crystals melt at 30°C giving a yellow liquid which decomposes at 40°C to give brown NO<sub>2</sub>. The decomposition occurs with explosion.

$$2N_2O_5 \longrightarrow 4NO_2 + O_2$$

(b) It is an acidic oxide. It reacts with water with hissing sound forming nitric acid.

$$N_2O_5 + H_2O \longrightarrow 2HNO_3$$

On account of this, it is known as nitric anhydride. With alkalies it forms nitrates.

$$2NaOH + N_2O_5 \longrightarrow 2NaNO_3 + H_2O$$

(c) It acts as a strong oxidising agent. It affects organic substances such as cork, rubber, etc. It oxidises iodine readily into iodine pentoxide.

$$I_2 + 5N_2O_5 \longrightarrow I_2O_5 + 10NO_2$$

(d) With aqueous NaCl, the ionic reaction takes place.

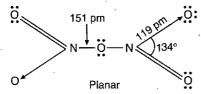

$$N_2O_5 + NaCl \longrightarrow NaNO_3 + NO_2Cl$$

The reaction proves that  $N_2O_5$  exists as ionic nitronium nitrate  $(NO_2^+ NO_3^-)$ .

(e) N<sub>2</sub>O<sub>5</sub> is decomposed by alkali metals.

$$N_2O_5 + Na \longrightarrow NaNO_3 + NO_2 \uparrow$$

**Structure:** In the gaseous state, it exists as a symmetrical molecule having the structure  $O_2N-O-NO_2$ . N-O-N bond is almost linear. It may be represented as:

X-ray studies suggest that solid  $N_2O_5$  is ionic in nature, *i.e.*, nitronium nitrate,  $NO_2^+$   $NO_3^-$ .

#### 5. Oxyacids of Nitrogen

Nitrogen forms a number of oxyacids. The most common and important oxyacids are:

(i) Nitrous acid, HNO2 and (ii) Nitric acid, HNO3.

#### (I) Nitrous Acid, HNO<sub>2</sub>

The free acid is unknown. It is known only in solution.

**Preparation:** Nitrous acid is unstable and is usually prepared when needed as an aqueous solution. A solution of nitrous acid can be prepared by acidifying solutions of nitrites with mineral acids.

$$2NaNO_2 + H_2SO_4 \longrightarrow Na_2SO_4 + 2HNO_2$$
  
 $KNO_2 + HCl \longrightarrow KCl + HNO_2$ 

Nitrates on heating with lead decompose to give nitrite.

$$NaNO_3 + Pb \xrightarrow{\Delta} NaNO_2 + PbO$$

An aqueous solution of the acid, free from any salt, can be prepared by treating barium nitrite with calculated amount of dilute sulphuric acid. Since the acid is very unstable, the reaction is carried out at low temperature (freezing mixture temperature). The insoluble barium sulphate is filtered off.

$$Ba(NO_2)_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HNO_2$$
Insoluble

A solution of nitrous acid may also be prepared by dissolving  $N_2O_3$  in water.

$$N_2O_3 + H_2O \longrightarrow 2HNO_2$$

**Properties:** (a) Aqueous solution of nitrous acid is pale blue. This is due to the presence of nitrogen trioxide,  $N_2O_3$ . The colour fades on standing for sometime.

(b) It is a weak acid and reacts with alkalies to form salts known as nitrites.

$$HNO_2 + NaOH \longrightarrow NaNO_2 + H_2O$$

(c) Auto-oxidation: The acid is unstable and even in cold solution, it undergoes auto-oxidation.

$$2HNO_2 \longrightarrow 2NO + H_2O + O$$

$$HNO_2 + O \longrightarrow HNO_3$$

$$3HNO_2 \longrightarrow 2NO + HNO_3 + H_2O$$

On heating, it decomposes into nitric oxide and nitrogen dioxide.

$$2HNO_2 \longrightarrow H_2O + N_2O_3$$

NO + NO<sub>2</sub>

(Brown)

(d) **Oxidising nature:** It acts as an oxidising agent due to ease with which it decomposes to give nascent oxygen. The potential equation when it acts as an oxidising agent is:

$$2HNO_2 \longrightarrow H_2O + 2NO + O$$

(i) Iodine is liberated from potassium iodide.

$$2KI + H_2SO_4 + 2HNO_2 \longrightarrow K_2SO_4 + 2NO + I_2 + 2H_2O$$

- (ii) Stannous chloride is oxidised to stannic chloride.
- $SnCl_2 + 2HCl + 2HNO_2 \longrightarrow SnCl_4 + 2NO + 2H_2O$

(iii) Sulphur dioxide is oxidised to sulphuric acid.  

$$SO_2 + 2HNO_2 \longrightarrow H_2SO_4 + 2NO$$

(iv) Sulphur is formed by oxidation of hydrogen sulphide.  $H_2S + 2HNO_2 \longrightarrow S + 2H_2O + 2NO$ 

(v) Actument retrous surplinate is oxidised to terms surplinate.  $2\text{FeSO}_4 + \text{H}_2\text{SO}_4 + 2\text{HNO}_2 \longrightarrow \text{Fe}_2(\text{SO}_4)_3 + 2\text{NO} + 2\text{H}_2\text{O}$ 

(vi) Sodium arsenite is oxidised to sodium arsenate.

$$Na_3AsO_3 + 2HNO_2 \longrightarrow Na_3AsO_4 + 2NO + H_2O$$

(e) **Reducing nature:** Nitrous acid acts as a reducing agent as it can be oxidised into nitric acid.

$$HNO_2 + O \longrightarrow HNO_3$$

(i) It reduces bromine to hydrobromic acid.

$$Br_2 + H_2O + HNO_2 \longrightarrow 2HBr + HNO_3$$

(ii) Acidified potassium permanganate is decolourised.

$$2KMnO_4 + 3H_2SO_4 + 5HNO_2 \longrightarrow$$

$$K_2SO_4 + 2MnSO_4 + 5HNO_3 + 3H_2O$$

(iii) Acidified potassium dichromate is reduced to chromic sulphate (green).

$$K_2Cr_2O_7 + 4H_2SO_4 + 3HNO_2 \longrightarrow$$
  
 $K_2SO_4 + Cr_2(SO_4)_3 + 3HNO_3 + 4H_2O_4$ 

(iv) Hydrogen peroxide is reduced to water.

$$H_2O_2 + HNO_2 \longrightarrow HNO_3 + H_2O$$

(f) **Reaction with ammonia:** It reacts with ammonia to form nitrogen and water.

$$NH_3 + HNO_2 \longrightarrow [NH_4NO_2] \longrightarrow N_2 + 2H_2O$$
Intermediate

(g) **Reaction with urea:** It decomposes urea and other aliphatic primary amines to nitrogen.

$$NH_2CONH_2 + 2HNO_2 \longrightarrow 2N_2 + CO_2 + 3H_2O$$
Urea
 $C_2H_5NH_2 + HO \cdot NO \longrightarrow C_2H_5OH + N_2 + H_2O$ 

(h) Reaction with aniline and other aromatic amines: It forms diazo compounds with aromatic amines at low temperatures.

$$C_6H_5NH_2\cdot HCl + HNO_2 \longrightarrow C_6H_5N = NCl + 2H_2O$$
Aniline hydro-
chloride

Aniline hydro-
chloride

Chloride

**Uses:** (i) It is used in organic chemistry in the preparation of diazo compounds which are employed for making aniline dves.

- (ii) It is also used for the replacement of —NH<sub>2</sub> group by—OH group in aliphatic primary amines.
- (iii) In analytical chemistry, it is used both as an oxidising and reducing agent.

**Structure:** Since nitrous acid forms two types of organic derivatives, the nitrites (R—ONO) and nitro compounds (R—NO<sub>2</sub>), it is considered to be a tautomeric mixture of two forms.

Note: Possible oxidation state of nitrogen lies between +5 and -3. In HNO<sub>2</sub>; oxidation state of nitrogen is +3; the oxidation state may increase up to +5 and decrease up to -3. Thus, HNO<sub>2</sub> acts both as oxidising and reducing agent. On the other hand in HNO<sub>3</sub>, oxidation state of nitrogen is +5, thus, it acts only as oxidising agent (itself undergoing reduction till -3 oxidation state is achieved).

#### (II) Nitric Acid, HNO<sub>3</sub>

It was named **aqua fortis** (meaning strong water) by alchemists. Glauber obtained it by the action of sulphuric acid on nitre.

**Laboratory preparation:** It is prepared in the laboratory by heating a mixture of alkali nitrate and concentrated sulphuric acid in a glass retort as shown in Fig. 10.5.

$$KNO_3 + H_2SO_4 \longrightarrow KHSO_4 + HNO_3$$

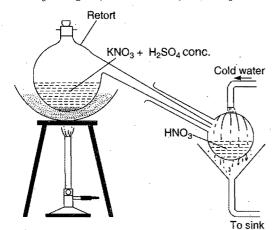

Fig. 10.5 Laboratory preparation of nitric acid

The vapours of nitric acid evolved are condensed in a glass receiver. The nitric acid thus obtained may contain oxides of nitrogen as impurity. The dissolved oxides of nitrogen are removed by redistillation or blowing a current of carbon dioxide through warm acid.

**Manufacture:** Nitric acid is of great commercial importance as it is needed in large amounts for the manufacture of explosives, fertilizers, dyes, drugs, etc. Before world war I, the only available method for the manufacture of nitric acid was the distilling of nitre with concentrated sulphuric acid. Now-a-days the following two processes are employed for the manufacture of nitric acid:

- (i) Birkeland and Eyde process or Arc process.
- (ii) Ostwald's process. This process is most recent.

#### (a) Birkeland and Eyde Process

**Principle:** The reaction between nitrogen and oxygen is reversible and endothermic in nature.

$$N_2 + O_2 \Longrightarrow 2NO -43,200$$
 calories

According to Le Chatelier's principle, the formation of nitric oxide is favoured by high temperature. The temperature is thus maintained about 3000°C by the use of an electric arc. The nitric oxide formed is immediately cooled to 1000°C as to prevent its decomposition. Nitric oxide further combines with oxygen to form nitrogen dioxide.

$$2NO + O_2 \longrightarrow 2NO_2$$

The vapours are then passed through water when nitric acid is produced.

$$2NO_2 + H_2O \longrightarrow HNO_3 + HNO_2$$
  
 $3HNO_2 \longrightarrow HNO_3 + 2NO + H_2O$ 

**Process:** Air is blown into an electric arc established between two water cooled copper electrodes and spread into a disc with the help of a strong magnetic field applied at right angles (Fig. 10.6). The electric arc produces a temperature of about 3000°C. Nitrogen and oxygen combine to form nitric oxide. The gases coming out of this furnace consists of 1.25 to 2% nitric oxide. These gases are cooled down quickly to 1000°C. The gases are further cooled to 150°C by passing through boiler pipes. The gases now enter the oxidation chamber where nitric oxide combines with oxygen and is oxidised to

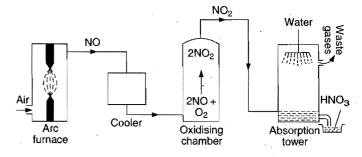

Fig. 10.6 Manufacture of nitric acid

nitrogen dioxide. Nitrogen dioxide thus produced is absorbed in water in the absorption tower (70 ft high and 20 ft in diameter) packed with quartz. The nitric acid in the first tower reaches a strength of 30 to 40% while in the succeeding towers, the strength is about 20, 10 and 5% respectively.

The utility of this method has declined gradually and today it is practically outdated because the yield in this process is very poor and the consumption of electrical power is high.

#### (b) Ostwald's Process (Modern Process)

**Principle:** The mixture of ammonia and air when passed over platinum gauze catalyst at 750–900°C, the ammonia is oxidised to nitric oxide (NO),

$$4NH_3 + 5O_2 \xrightarrow{Pt} 4NO + 6H_2O + 21,600$$
 calories

The reaction is exothermic and the heat of reaction maintains the temperature of the catalyst.

The nitric oxide is then oxidised to nitrogen dioxide, (NO<sub>2</sub>), by  $O_2$  from the air which is cooled to  $50^{\circ}$ C and absorbed in water. The resulting NO can be volatilized and recycled.

$$2NO + O_2 \longrightarrow 2NO_2$$
  
 $3NO_2 + H_2O \longrightarrow 2HNO_3 + NO$ 

**Process:** A mixture of dry ammonia and purified air (free from carbon dioxide and dust particles) in the ratio of 1:10 (by volume) is passed through the catalyst chamber containing platinum gauze (Fig. 10.7). The gauze is initially

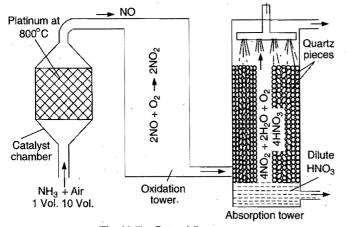

Fig.10.7 Ostwald's process

heated to about 800°C electrically. Subsequently, the temperature is maintained by heat of reaction. Ammonia is rapidly oxidised to nitric oxide. The yield varies from 90-95%.

The gases issuing from the converter are cooled and then mixed with air in large empty chamber known as oxidation chamber. Nitric oxide gets oxidised to nitrogen dioxide. Nitrogen dioxide is now absorbed in water in the absorption tower packed with broken quartz. The nitric oxide formed is again oxidised by oxygen and nitrogen dioxide is further absorbed by water. The total reaction thus is:

$$4NO_2 + 2H_2O + O_2 \longrightarrow 4HNO_3$$

The concentration of acid produced is about 50-60%.

Concentration of nitric acid: Dilute nitric acid (50-60%) obtained in the above process is concentrated by distillation till a constant boiling mixture (b.pt. 121°C) is formed. This is ordinary concentrated nitric acid (sp. gr. 1.414) and its strength is 68%. More concentrated HNO<sub>3</sub> is produced by distilling the ordinary concentrated nitric acid with concentrated sulphuric acid. The distillate is 98% HNO<sub>3</sub> (sp. gr. 1.51). The cent per cent HNO<sub>3</sub> is obtained by cooling 98% HNO<sub>3</sub> in a freezing mixture. The colourless crystals (m.pt. -42°C) are melted to get 100% HNO<sub>3</sub>.

Fuming nitric acid: It contains dissolved NO<sub>2</sub> in concentrated nitric acid. It is brown in colour. Fuming acid is obtained by distilling concentrated HNO<sub>3</sub> with a little starch. Nitric acid is reduced by starch into NO<sub>2</sub> which dissolves in the remaining acid to form fuming nitric acid. Fuming nitric acid is a strong oxidising agent.

Physical properties: Anhydrous nitric acid is a colour-less fuming liquid having a pungent smell. Concentrated nitric acid is often pale yellow as a result of partial decomposition of the acid to NO<sub>2</sub>. It boils at 84.1°C and freezes at -42°C. It is soluble in water in all proportions. The aqueous solution containing about 68% of HNO<sub>3</sub> by weight forms a constant boiling mixture. This is the ordinary concentrated HNO<sub>3</sub> (sp. gr. 1.414). Nitric acid usually acquires yellow colour due to its decomposition by sunlight into NO<sub>2</sub>.

$$4\text{HNO}_3 \xrightarrow{\text{Sunlight}} 4\text{NO}_2 + 2\text{H}_2\text{O} + \text{O}_2$$

The yellow colour of the acid can be removed by warming it to 60-80°C and bubbling dry air through it.

It has extremely corrosive action on the skin and causes painful sores.

#### **Chemical properties:**

(A) It is a very strong acid. It exhibits usual properties of acids. It reacts with basic oxides, carbonates, bicarbonates and hydroxides forming corresponding salts.

$$CaO + 2HNO_3 \longrightarrow Ca(NO_3)_2 + H_2O$$
  
 $Na_2CO_3 + 2HNO_3 \longrightarrow 2NaNO_3 + H_2O + CO_2$   
 $NaOH + HNO_3 \longrightarrow NaNO_3 + H_2O$ 

#### (B) Oxidising nature

Nitric acid acts as a strong oxidising agent as it decomposes to give nascent oxygen easily.

$$2HNO_3 \longrightarrow H_2O + 2NO_2 + O$$

$$2HNO_3 \longrightarrow H_2O + 2NO + 3O$$

- (i) Oxidation of non-metals: The nascent oxygen oxidises various non-metals to their corresponding highest oxyacids.
  - (1) Sulphur is oxidised to sulphuric acid.

$$[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 3$$

$$S + 3O + H_2O \longrightarrow H_2SO_4$$

$$S + 6HNO_3 \longrightarrow H_2SO_4 + 6NO_2 + 2H_2O$$
Conc. and hot

(2) Carbon is oxidised to carbonic acid.

$$[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 2$$

$$C + 2O + H_2O \longrightarrow H_2CO_3$$

$$C + 4HNO_3 \longrightarrow H_2CO_3 + 4NO_2 + H_2O$$

(3) Phosphorus is oxidised to orthophosphoric acid.

$$[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 5$$

$$2P + 5O + 3H_2O \longrightarrow 2H_3PO_4$$

$$2P + 10HNO_3 \longrightarrow 2H_3PO_4 + 10NO_2 + 2H_2O$$
Conc. and hot

(4) Iodine is oxidised to iodic acid.

$$[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 5$$

$$I_2 + 5O + H_2O \longrightarrow 2HIO_3$$

$$I_2 + 10HNO_3 \longrightarrow 2HIO_3 + 10NO_2 + 4H_2O$$
Conc. and hot

- (ii) Oxidation of metalloids: Metalloids like non-metals also form highest oxyacids.
  - (1) Arsenic is oxidised to arsenic acid.

$$[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 5$$

$$2As + 5O + 3H_2O \longrightarrow 2H_3AsO_4$$

$$2As + 10HNO_3 \longrightarrow 2H_3AsO_4 + 10NO_2 + 2H_2O$$
or
$$As + 5HNO_3 \longrightarrow H_3AsO_4 + 5NO_2 + H_2O$$
Conc. and hot

(2) Antimony is oxidised to antimonic acid.

Sb + 5HNO<sub>3</sub> 
$$\longrightarrow$$
 H<sub>3</sub>SbO<sub>4</sub> + 5NO<sub>2</sub> + H<sub>2</sub>O  
Conc. and hot

(3) Tin is oxidised to metastannic acid.

$$[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 2$$

$$Sn + 2O + H_2O \longrightarrow H_2SnO_3$$

$$Sn + 4HNO_3 \longrightarrow H_2SnO_3 + 4NO_2 + H_2O$$

(iii) Oxidation of compounds: (1) Sulphur dioxide is oxidised to sulphuric acid.

$$2HNO_3 \longrightarrow H_2O + 2NO_2 + O$$

$$SO_2 + O + H_2O \longrightarrow H_2SO_4$$

$$SO_2 + 2HNO_3 \longrightarrow H_2SO_4 + 2NO_2$$

(2) Hydrogen sulphide is oxidised to sulphur.

$$2HNO_3 \longrightarrow H_2O + 2NO_2 + O$$

$$H_2S + O \longrightarrow H_2O + S$$

$$H_2S + 2HNO_3 \longrightarrow 2NO_2 + 2H_2O + S$$

(3) Ferrous sulphate is oxidised to ferric sulphate in presence of H<sub>2</sub>SO<sub>4</sub>.

$$2HNO_{3} \longrightarrow H_{2}O + 2NO + 3O$$

$$[2FeSO_{4} + H_{2}SO_{4} + O \longrightarrow Fe_{2}(SO_{4})_{3} + H_{2}O] \times 3$$

 $6FeSO_4 + 3H_2SO_4 + 2HNO_3 \longrightarrow 3Fe_2(SO_4)_3 + 2NO + 4H_2O$ 

NO is absorbed by ferrous sulphate and a dark brown ring of nitroso ferrous sulphate is formed. This is the ring test for nitrates. [Nitrate + ferrous sulphate + conc. sulphuric acid  $\longrightarrow$  a brown ring (FeSO<sub>4</sub>NO)]

(4) Iodine is liberated from KI.

$$2HNO_3 \longrightarrow 2NO + H_2O + 3O$$

$$[2KI + 2HNO_3 + O \longrightarrow 2KNO_3 + I_2 + H_2O] \times 3$$

$$6KI + 8HNO_3 \longrightarrow 6KNO_3 + 2NO + 3I_2 + 4H_2O$$

(5) HBr, HI are oxidised to Br<sub>2</sub> and I<sub>2</sub>, respectively.

$$2HNO_3 \longrightarrow H_2O + 2NO_2 + O$$

$$2HBr + O \longrightarrow H_2O + Br_2$$

$$2HBr + 2HNO_3 \longrightarrow Br_2 + 2NO_2 + 2H_2O$$
Similarly,  $2HI + 2HNO_3 \longrightarrow I_2 + 2NO_2 + 2H_2O$ 

(6) Ferrous sulphide is oxidised to ferrous sulphate.

$$[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 4$$

$$FeS + 4O \longrightarrow FeSO_4$$

$$FeS + 8HNO_3 \longrightarrow FeSO_4 + 8NO_2 + 4H_2O$$

(7) Stannous chloride is oxidised to stannic chloride in presence of HCl.

$$[SnCl_2 + 2HCl \longrightarrow SnCl_4 + 2H] \times 7$$

$$2HNO_3 + 14H \longrightarrow NH_2OH + NH_3 + 5H_2O$$

$$Hydroxylamine$$

$$NH_3 + HNO_3 \longrightarrow NH_4NO_3$$

$$7SnCl_2 + 14HCl + 3HNO_3 \longrightarrow 7SnCl_4 + NH_2OH + NH_4NO_3 + 5H_2O$$

(8) Cane sugar is oxidised to oxalic acid.

$$C_{12}H_{22}O_{11} + 36HNO_3 \longrightarrow 6(COOH)_2 + 36NO_2 + 23H_2O$$

#### (C) Action on metals

Most of the metals with the exception of noble metals like gold and platinum are attacked by nitric acid. Nitric acid plays a double role in the action of metals, *i.e.*, it acts as an acid as well as an oxidising agent. Armstrong postulated that primary action of nitric acid is to produce hydrogen in the nascent form. Before this hydrogen is allowed to escape, it reduces the nitric acid into number of products like NO<sub>2</sub>, NO, N<sub>2</sub>O, N<sub>2</sub> or NH<sub>3</sub> according to the following reactions:

Metal + HNO<sub>3</sub> 
$$\longrightarrow$$
 Nitrate + H  
2HNO<sub>3</sub> + 2H  $\longrightarrow$  2NO<sub>2</sub> + 2H<sub>2</sub>O  
2HNO<sub>3</sub> + 6H  $\longrightarrow$  2NO + 4H<sub>2</sub>O  
2HNO<sub>3</sub> + 10H  $\longrightarrow$  N<sub>2</sub> + 6H<sub>2</sub>O  
2HNO<sub>3</sub> + 16H  $\longrightarrow$  2NH<sub>3</sub> + 6H<sub>2</sub>O

The progress of the reaction is controlled by a number of factors:

- (a) the nature of the metal,
- (b) the concentration of the acid,
- (c) the temperature of the reaction,
- (d) the presence of other impurities.

According to another view, reduction of nitric acid with nascent hydrogen occurs only in the case of those metals which are above hydrogen in the electrochemical series. In the case of metals which are below the hydrogen in the electrochemical series, the formation of hydrogen is not possible and thus metals are oxidised by nitric acid. The oxide formed being basic in nature reacts with nitric acid to form nitrate.

$$HNO_3 \longrightarrow O$$
 $Metal + O \longrightarrow Oxide$ 
 $Oxide + HNO_3 \longrightarrow Nitrate + Water$ 

### (1) Metals which are above hydrogen in electrochemical series :

(i) When hydrogen is given off: Magnesium and manganese are the metals that liberate hydrogen with dilute nitric acid.

$$\begin{array}{c} \text{Mg} + 2\text{HNO}_3 \longrightarrow \text{Mg(NO}_3)_2 + \text{H}_2 \\ \\ \text{Dilute} \end{array}$$

$$\text{Mn} + 2\text{HNO}_3 \longrightarrow \text{Mn(NO}_3)_2 + \text{H}_2 \\ \\ \text{Dilute} \end{array}$$

# (ii) When metal nitrates are formed and nitric acid is reduced:

(a) Zinc: It reacts with very dilute nitric acid (6%) to form ammonium nitrate.

$$[Zn + 2HNO_3 \longrightarrow Zn(NO_3)_2 + 2H] \times 4$$

$$HNO_3 + 8H \longrightarrow NH_3 + 3H_2O$$

$$NH_3 + HNO_3 \longrightarrow NH_4NO_3$$

$$4Zn + 10HNO_3 \longrightarrow 4Zn(NO_3)_2 + NH_4NO_3 + 3H_2O$$
V. dilute

It reacts with dil. HNO $_3\,(20\%)$  to form nitrous oxide (N $_2\mathrm{O}$ ).

$$[Zn + 2HNO_3 \longrightarrow Zn(NO_3)_2 + 2H] \times 4$$

$$2HNO_3 + 8H \longrightarrow N_2O + 5H_2O$$

$$4Zn + 10HNO_3 \longrightarrow 4Zn(NO_3)_2 + N_2O + 5H_2O$$

It reacts with conc. HNO<sub>3</sub> (70%) to form nitrogen dioxide (NO<sub>2</sub>).

$$Zn + 2HNO_3 \longrightarrow Zn(NO_3)_2 + 2H$$

$$[HNO_3 + H \longrightarrow NO_2 + H_2O] \times 2$$

$$Zn + 4HNO_3 \longrightarrow Zn(NO_3)_2 + 2NO_2 + 2H_2O$$

$$Conc.$$

**(b) Iron:** Iron with very dilute nitric acid forms ammonium nitrate.

$$4Fe + 10HNO_3 \longrightarrow 4Fe(NO_3)_2 + NH_4NO_3 + 3H_2O$$
Ferrous nitrate

Iron with dilute nitric acid forms nitrous oxide.

$$4Fe + 10HNO_3 \longrightarrow 4Fe(NO_3)_2 + N_2O + 5H_2O$$
Dilute

Iron with conc. HNO<sub>3</sub> forms nitrogen dioxide (NO<sub>2</sub>).

Fe + 3HNO<sub>3</sub> 
$$\longrightarrow$$
 Fe(NO<sub>3</sub>)<sub>3</sub> + 3H  
[HNO<sub>3</sub>+H  $\longrightarrow$  NO<sub>2</sub> + H<sub>2</sub>O] × 3  
Fe + 6HNO<sub>3</sub>  $\longrightarrow$  Fe(NO<sub>3</sub>)<sub>3</sub> + 3NO<sub>2</sub> + 3H<sub>2</sub>O  
Conc. Ferric nitrate

Iron is rendered passive by highly concentrated nitric acid 80%.

(c) Tin: Tin forms ammonium nitrate with dilute nitric acid.

$$4Sn + 10HNO_3 \longrightarrow 4Sn(NO_3)_2 + NH_4NO_3 + 3H_2O$$
Dilute Stannous nitrate

Tin forms metastannic acid with conc. HNO<sub>3</sub> and evolves nitrogen dioxide.

$$Sn + 4HNO_3 \longrightarrow H_2SnO_3 + 4NO_2 + H_2O$$
  
Hot conc. Metastannic acid

(d) Lead: It forms nitric oxide with dilute HNO<sub>3</sub>.

[Pb + 2HNO<sub>3</sub>  $\longrightarrow$  Pb(NO<sub>3</sub>)<sub>2</sub> + 2H] × 3

[HNO<sub>3</sub> + 3H  $\longrightarrow$  NO + 2H<sub>2</sub>O] × 2

3Pb + 8HNO<sub>3</sub>  $\longrightarrow$  3Pb(NO<sub>3</sub>)<sub>2</sub> + 2NO + 4H<sub>2</sub>O

It forms nitrogen dioxide with conc. HNO<sub>3</sub>.

Pb + 2HNO<sub>3</sub> 
$$\longrightarrow$$
 Pb(NO<sub>3</sub>)<sub>2</sub> + 2H  
[HNO<sub>3</sub> + H  $\longrightarrow$  NO<sub>2</sub> + H<sub>2</sub>O] × 2  
Pb + 4HNO<sub>3</sub>  $\longrightarrow$  Pb(NO<sub>3</sub>)<sub>2</sub> + 2NO<sub>2</sub> + 2H<sub>2</sub>O

# (2) Metals which are below hydrogen in the electrochemical series:

(a) Copper: Copper with cold dil. HNO<sub>3</sub> forms nitric oxide (NO).

$$2HNO_{3} \longrightarrow H_{2}O + 2NO + 3O$$

$$[Cu + O \longrightarrow CuO] \times 3$$

$$[CuO + 2HNO_{3} \longrightarrow Cu(NO_{3})_{2} + H_{2}O] \times 3$$

$$3Cu + 8HNO_{3} \longrightarrow 3Cu(NO_{3})_{2} + 2NO + 4H_{2}O$$

Copper with hot conc. HNO<sub>3</sub> forms nitrogen dioxide (NO<sub>2</sub>).

$$2HNO_{3} \longrightarrow H_{2}O + 2NO_{2} + O$$

$$Cu + O \longrightarrow CuO$$

$$CuO + 2HNO_{3} \longrightarrow Cu(NO_{3})_{2} + H_{2}O$$

$$Cu + 4HNO_{3} \longrightarrow Cu(NO_{3})_{2} + 2NO_{2} + 2H_{2}O$$

$$Hot conc.$$

**(b)** Silver: Silver behaves similarly as copper.

$$3Ag + 4HNO_3 \longrightarrow 3AgNO_3 + NO + 2H_2O$$

$$Dilute$$

$$Ag + 2HNO_3 \longrightarrow AgNO_3 + NO_2 + H_2O$$

(c) Mercury: Mercury with dilute nitric acid forms mercurous nitrate and nitric oxide.

$$2HNO_{3} \longrightarrow H_{2}O + 2NO + 3O$$

$$[2Hg + O \longrightarrow Hg_{2}O] \times 3$$

$$[Hg_{2}O + 2HNO_{3} \longrightarrow Hg_{2}(NO_{3})_{2} + H_{2}O] \times 3$$

$$6Hg + 8HNO_{3} \longrightarrow 3Hg_{2}(NO_{3})_{2} + 2NO + 4H_{2}O$$
Dilute

Mercurous nitrate

Mercury with conc. HNO<sub>3</sub> forms mercuric nitrate and nitrogen dioxide.

$$2HNO_{3} \longrightarrow H_{2}O + 2NO_{2} + O$$

$$Hg + O \longrightarrow HgO$$

$$HgO + 2HNO_{3} \longrightarrow Hg(NO_{3})_{2} + H_{2}O$$

$$Hg + 4HNO_{3} \longrightarrow Hg(NO_{3})_{2} + 2NO_{2} + 2H_{2}O$$

$$Conc. \qquad Mercuric nitrate$$

#### Summary:

Concentration of nitric acid	Metal	Main products
Very Dilute HNO <sub>3</sub>	Mg, Mn	H <sub>2</sub> + metal nitrate
very Dilute 111403	Fe, Zn, Sn	NH <sub>4</sub> NO <sub>3</sub> + metal nitrate
	Pb, Cu, Ag, Hg	NO + metal nitrate
Dilute HNO <sub>3</sub>	Fe, Zn	N <sub>2</sub> O + metal nitrate
	Sn	$NH_4NO_3 + Sn(NO_3)_2$
	Zn, Fe, Pb, Cu, Ag	NO <sub>2</sub> + metal nitrate
Conc. HNO <sub>3</sub>	Sn	NO <sub>2</sub> + H <sub>2</sub> SnO <sub>3</sub> Metastannic acid

(3) Metals which become passive: The concentrated nitric acid renders metals like iron, cobalt, nickel, chromium, etc., passive. Aluminium is also rendered passive by nitric acid.

The inertness exhibited by metals under conditions in which chemical activity is expected is known as passivity. For example, iron displaces copper from copper sulphate solution. This property of iron is lost if it is dipped in conc. HNO<sub>3</sub>. The phenomenon of passivity (inertness) is best explained by assuming the formation of a thin film of oxide on the surface of the metal which prevents the action of the reagent.

(4) Metals which do not react: Noble metals like gold, platinum, iridium, rhodium, etc., are not acted upon by nitric acid. However, these metals dissolve in aqua-regia (3 parts conc. HCl and one part conc. HNO<sub>3</sub>). Aqua-regia forms nascent chlorine which attacks these metals.

#### Gold:

$$[HNO_3 + 3HCl \longrightarrow NOCl + 2H_2O + 2Cl] \times 3$$

$$[Au + 3Cl \longrightarrow AuCl_3] \times 2$$

$$[AuCl_3 + HCl \longrightarrow HAuCl_4] \times 2$$

$$2Au + 3HNO_3 + 11HCl \longrightarrow 2HAuCl_4 + 3NOCl + 6H_2O$$
Chloroauric acid

#### Platinum:

$$[HNO_3 + 3HCl \longrightarrow NOCl + 2H_2O + 2Cl] \times 2$$

$$Pt + 4Cl \longrightarrow PtCl_4$$

$$PtCl_4 + 2HCl \longrightarrow H_2PtCl_6$$

$$Pt + 2HNO_3 + 8HCl \longrightarrow H_2PtCl_6 + 2NOCl + 4H_2O$$

$$Chloroplatinic acid$$

### (D) Action on organic compounds

(i) Nitration: The replacement of one or more hydrogen atoms of an organic compound by a nitro group (— $NO_2$ ) is known as nitration. The nitration occurs in presence of conc. sulphuric acid with the formation of nitronium ion,  $NO_2^+$ .

$$HNO_3 + 2H_2SO_4 \Longrightarrow NO_2^+ + 2HSO_4^- + H_3O_4^+$$
  
Nitronium ion Hydronium io

Benzene and phenol when treated with a mixture of conc. HNO<sub>3</sub> and conc. H<sub>2</sub>SO<sub>4</sub> form nitrobenzene and trinitro phenol (picric acid) respectively.

Benzene + HONO<sub>2</sub> 
$$\xrightarrow{H_2SO_4}$$
  $\xrightarrow{NO_2}$   $\xrightarrow{H_2O}$  Nitrobenzene OH  $\xrightarrow{OH}$   $\xrightarrow{OH}$   $\xrightarrow{NO_2}$  + 3HONO<sub>2</sub>  $\xrightarrow{H_2SO_4}$   $\xrightarrow{O_2N}$   $\xrightarrow{NO_2}$  + 3H<sub>2</sub>O Phenol NO<sub>2</sub> Picric acid

Glycerol with conc. HNO<sub>3</sub> in presence of conc. H<sub>2</sub>SO<sub>4</sub> below 25°C forms glycerol trinitrate (Nitroglycerine).

$$\begin{array}{c|c} \text{CH}_2\text{OH} & \text{CH}_2\text{ONO}_2 \\ | & \text{CHOH} + 3\text{HONO}_2 & \xrightarrow{\text{H}_2\text{SO}_4} & \text{CHONO}_2 + 3\text{H}_2\text{O} \\ | & \text{CH}_2\text{OH} & \text{CH}_2\text{ONO}_2 \\ | & \text{Nitroglycerine} \end{array}$$

**Action on proteins:** Nitric acid attacks proteins forming a yellow nitro compound called **xanthoprotein**. It, therefore, stains skin and renders wool yellow. This property is utilised for the test of proteins.

(ii) Oxidation: A number of organic compounds are oxidised.

Sawdust catches fire when nitric acid is poured on it. Turpentine oil bursts into flames when treated with fuming nitric acid. Cane sugar is oxidised to oxalic acid. Toluene is oxidised to benzoic acid with dil. HNO<sub>3</sub>.

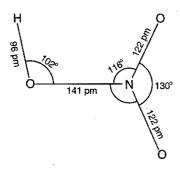

$$\begin{array}{cccc}
CH_3 & COOH \\
& & + & 3O \xrightarrow{\text{Dil. HNO}_3} & & & + & H_2O
\end{array}$$
Benzoic acid

Uses: Nitric acid is used:

- (i) in the manufacture of explosives like T.N.T. (trinitrotoluene), picric acid, nitroglycerine, dynamite, etc.
- (ii) in the manufacture of fertilizers like ammonium nitrate, basic calcium nitrate, etc.
- (iii) in the manufacture of artificial silk, dyes, drugs, perfumes, etc.
  - (iv) in the purification of silver and gold.
  - (v) as a laboratory reagent.
- (vi) as a solvent for metals, for etching designs on wares of brass, bronze, etc.
  - (vii) in the preparation of aqua-regia.
  - (viii) in the manufacture of sulphuric acid.
  - (ix) for nitration of organic compounds.
- (x) for the manufacture of nitrates such as silver nitrate, sodium nitrate, potassium nitrate, etc.

**Structure:** Nitric acid is a monobasic acid, *i.e.*, the molecule consists of one hydroxyl group as it is formed by the hydrolysis of nitryl chloride, NO<sub>2</sub>Cl. It may be structurally represented as below:

Gaseous nitric acid is a planar molecule. The bond lengths and bond angles as present in the molecule are represented in the figure:

It is supposed to exist in two resonating forms.

## 10.5 NITRATES

The salts of nitric acid are called nitrates. Sodium and potassium nitrates occur in nature while others are prepared by the action of nitric acid on metals, metallic oxides, hydroxides, carbonates, bicarbonates, sulphites, etc.

$$\begin{array}{c} \text{Ag} + 2\text{HNO}_3 \longrightarrow \text{AgNO}_3 + \text{NO}_2 + \text{H}_2\text{O} \\ \text{KOH} + \text{HNO}_3 \longrightarrow \text{KNO}_3 + \text{H}_2\text{O} \\ \text{CaCO}_3 + 2\text{HNO}_3 \longrightarrow \text{Ca(NO}_3)_2 + \text{H}_2\text{O} + \text{CO}_2 \end{array}$$

$$NaHCO_3 + HNO_3 \longrightarrow NaNO_3 + H_2O + CO_2$$
  
 $Na_2SO_3 + 2HNO_3 \longrightarrow 2NaNO_3 + SO_2 + H_2O$ 

**Properties: (i)** Nitrates are generally soluble in water. A few nitrates hydrolyse.

$$Bi(NO_3)_3 + 3H_2O \Longrightarrow Bi(OH)_3 + 3HNO_3$$
  
White ppt.

- (ii) Action of heat: Nitrates are decomposed on heating.
  - (a) Alkali nitrates form nitrites and oxygen on heating.

$$2NaNO_3 \longrightarrow 2NaNO_2 + O_2$$
  
 $2KNO_3 \longrightarrow 2KNO_2 + O_2$ 

(b) Nitrates of alkaline earth metals and heavy metals decompose to give mixture of nitrogen dioxide and oxygen along with a solid residue of metal oxide.

$$2\text{Ca}(\text{NO}_3)_2 \longrightarrow 2\text{CaO} + 4\text{NO}_2 + \text{O}_2$$
  
 $2\text{Pb}(\text{NO}_3)_2 \longrightarrow 2\text{PbO} + 4\text{NO}_2 + \text{O}_2$   
 $2\text{Cu}(\text{NO}_3)_2 \longrightarrow 2\text{CuO} + 4\text{NO}_2 + \text{O}_2$ 

(c) Nitrates of metals of low chemical activity decompose into corresponding metals and mixture of nitrogen dioxide and oxygen.

$$2AgNO_3 \longrightarrow 2Ag + 2NO_2 + O_2$$
  
 $Hg(NO_3)_2 \longrightarrow Hg + 2NO_2 + O_2$ 

(d) Ammonium nitrate decomposes to form nitrous oxide.

$$NH_4NO_3 \longrightarrow N_2O + 2H_2O$$

(iii) Action of conc. H<sub>2</sub>SO<sub>4</sub>: When heated with conc. H<sub>2</sub>SO<sub>4</sub>, nitrates undergo double decomposition reaction forming free nitric acid. Some of the nitric acid get decomposed to give brown fumes of nitrogen dioxide.

$$KNO_3 + H_2SO_4 \longrightarrow KHSO_4 + HNO_3$$
  
 $4HNO_3 \longrightarrow 4NO_2 + 2H_2O + O_2$ 

(iv) Nitrates are good oxidising agents. These are used in gun powder and explosives.

#### **Tests for Nitrates**

- (a) Nitrate + conc.  $H_2SO_4 \xrightarrow{Heat}$  Brown fumes of  $NO_2$  are given off.
- (b) Nitrate + conc.  $H_2SO_4$  + copper turnings  $\xrightarrow{\text{Heat}}$  quick evolution of brown fumes of  $NO_2$ .
- (c) Aq. soln. of nitrate + freshly prepared soln. of ferrous sulphate + conc.  $H_2SO_4$  which is added carefully by the side of the test tube  $\longrightarrow$  A brown ring is formed at the junction of two liquids.

  - (e) Nitrate + Zn metal + dil.  $H_2SO_4 \xrightarrow{Boil \text{ for } 5 \text{ minutes}} Solution$

The solution is treated with few drops each of KI and starch solutions. Violet colouration is obtained.

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + 2H$$

Nascent hydrogen reduces nitrate into nitrite.

$$NaNO_3 + 2H \longrightarrow NaNO_2 + H_2O$$
  
 $2NaNO_2 + H_2SO_4 \longrightarrow Na_2SO_4 + 2HNO_2$ 

HNO<sub>2</sub> acid evolves iodine from KI which gives violet colouration with starch.

#### **DISTINCTION BETWEEN NITRITES AND NITRATES**

	Test	Nitrites	Nitrates
1.	Treat the salt with dilute HCl.	Brown fumes which turn FeSO <sub>4</sub> solution black.	No action.
2.		Dark brown colour even with dilute $H_2SO_4$ .	
3.	solution of the salt	lodine evolved, give blue colour with starch.	No action
4.	To the acidified salt solution add KMnO <sub>4</sub> solution.		No action.
5.	To the solution add brucine solution.	No action.	Red colouration.

## **PHOSPHORUS**

Phosphorus was discovered by Brand in 1669. Scheele isolated it from bone ash and Lavoisier in 1777 proved that phosphorus is an element. It glows in the dark and was, therefore, called phosphorus (Greek word, *phos* = light, and *phero* = I carry).

**Occurrence:** Since phosphorus is an active element, it is not found free in nature. It is widely distributed in nature in the combined state. It occurs as phosphates in the rocks and in the soil and as phosphoproteins in all living beings. Deoxyribonucleic acid (DNA) is a chainlike biological molecule in which informations about inheritable traits resides, contains phosphate groups along the length of its chain. Similarly, ATP (adenosine triphosphate), the energy containing molecule of living organisms, contains phosphate groups. It is an essential constituent of bones, teeth, blood and nervous tissues. It is necessary for the growth of plants. Bone ash contains about 80% calcium phosphate. It is present in milk, eggs and guano (excreta of seabirds). The principal minerals of phosphorus are:

(i) Phosphorite or phosphate rock Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>

(ii) Fluorapatite, 3Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>·CaF<sub>2</sub> or Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>F

(iii) Chlorapatite, 3Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>·CaCl<sub>2</sub> or Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>Cl

**Extraction:** Phosphorus is extracted either from phosphorite or bone ash by the application of following two processes:

- (i) Retort process or old process.
- (ii) Electrothermal process or modern process.

## (i) Retort process or old process:

The phosphorite mineral or bone ash is digested with concentrated sulphuric acid (about 60%). Insoluble calcium sulphate and orthophosphoric acid are formed.

$$Ca_3(PO_4)_2 + 3H_2SO_4 \longrightarrow 3CaSO_4 + 2H_3PO_4$$

The syrupy liquid is separated from insoluble residue by filtration. The liquid is evaporated when it changes into metaphosphoric acid with evolution of water.

$$H_3PO_4 \longrightarrow HPO_3 + H_2O$$
Metaphosphoric

The metaphosphoric acid is mixed with powdered coke and distilled in fireclay retorts at a bright red heat (Fig. 10.8). The acid is reduced to phosphorus by carbon which comes in vapourised form. The vapours are condensed below water.

$$4HPO_3 + 10C \longrightarrow P_4 + 10CO + 2H_2O$$

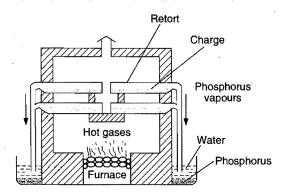

Fig. 10.8 Retort process

# (ii) Electrothermal process or modern process:

Phosphorus is prepared now a days by the direct reduction of mineral phosphorite, Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> by carbon in presence of silica. The mixture of phosphorite, (phosphate rock) with coke (C) and quartz sand (SiO<sub>2</sub>) is dried and then introduced into the electric furnace (Fig. 10.9). The furnace is an iron tank

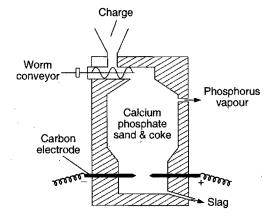

Fig. 10.9

lined inside with refractory bricks. Carbon electrodes are fitted on either side of the furnace. The furnace has two exits, one for removal of vapours in the upper part of the furnace and other for removal of slag in the lower part of the furnace. The charge is introduced through the closed hopper arrangement.

The mixture is heated at 1400-1500°C by the discharge of an alternating current between carbon electrodes. Silica combines with calcium phosphate and forms phosphorus pentoxide which is reduced by carbon into phosphorus. The overall reaction is,

$$[Ca3(PO4)2 + 3SiO2 \longrightarrow 3CaSiO3 + P2O5] \times 2$$
  
$$2P2O5 + 10C \longrightarrow P4 + 10CO$$

$$2Ca_3(PO_4)_2 + 6SiO_2 + 10C \longrightarrow 6CaSiO_3 + 10CO + P_4$$

Vapours of phosphorus and carbon monoxide leave the furnace through the upper exit and are condensed under water. The other product, calcium silicate glass (called *slag*) is tapped out periodically by an exit from the bottom of the furnace.

**Purification:** Phosphorus obtained is further purified by melting under acidified potassium dichromate solution when the impurities are oxidised. It is redistilled.

## Allotropic modifications of phosphorus

Phosphorus exists in a number of allotropic forms. These forms are:

- (i) Yellow or white phosphorus (ii) Red phosphorus
- (iii) Scarlet phosphorus
- (iv) α-black phosphorus
- (v) β-black phosphorus
- (vi) Violet phosphorus

The main allotropic forms, however, are white phosphorus and red phosphorus.

## White or yellow phosphorus:

This is the common variety and is obtained by the methods described above. This form is chemically very active.

**Properties:** (i) White phosphorus is a molecular, transparent waxy solid, (sp. gr. 1.8) with the formula P<sub>4</sub>.

- (ii) The pure form is white but attains yellow colour on long standing due to the formation of a thin film of the red variety on the surface.
  - (iii) It is a soft metal and can be cut easily with knife.
- (iv) It has characteristic garlic smell and is poisonous in nature. 0.15 g is the fatal dose. Vapours are also injurious. Persons working with phosphorus develop a disease in which the jaw bones decay. This disease is known as **phossy jaw.**
- (v) It is insoluble in water but readily soluble in carbon disulphide.
  - (vi) It melts at 44°C into a yellow liquid. It boils at 280°C.
- (vii) In contact with air, it undergoes slow combustion and glows in dark. This property is called **phosphorescence**.
- (viii) Its ignition temperature is low (about 30°C). It readily catches fire giving dense fumes of phosphorus pentoxide. It is, therefore, kept in water.

$$P_4 + 5O_2 \longrightarrow P_4O_{10}$$
 or  $2P_2O_5$ 

(ix) It dissolves in caustic alkalies on boiling in an inert atmosphere and forms phosphine.

$$\begin{array}{c} P_4 \,+\, 3NaOH \,+\, 3H_2O \longrightarrow 3NaH_2PO_2 \\ \text{Caustic} \\ \text{soda} \end{array} \begin{array}{c} + \quad PH_3 \\ \text{Phosphine} \end{array}$$

- (x) It is very poisonous and very reactive. If white phosphorus is left exposed to air, it bursts spontaneously into flame. Because of its reactivity with oxygen, white phosphorus is stored under water, in which it is insoluble.
- (xi) It directly combines with halogens forming first, trihalides and then pentahalides.

$$P_4 + 6Cl_2 \longrightarrow 4PCl_3$$
;  $P_4 + 10\hat{Cl}_2 \longrightarrow 4PCl_5$ 

(xii) It combines with a number of metals forming phosphides.

$$6Mg + P_4 \longrightarrow 2Mg_3P_2$$
 (Magnesium phosphide)  
 $6Ca + P_4 \longrightarrow 2Ca_3P_2$  (Calcium phosphide)

- (xiii) It combines with sulphur with explosive violence forming a number of sulphides such as  $P_2S_3$ ,  $P_2S_5$ ,  $P_4S_3$  and  $P_4S_7$ .
- (xiv) It acts as a strong reducing agent. It reduces nitric acid and sulphuric acid.

$$[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 10$$

$$P_4 + 10 O + 6H_2O \longrightarrow 4H_3PO_4$$

$$P_4 + 20HNO_3 \longrightarrow 4H_3PO_4 + 20NO_2 + 4H_2O$$

$$[H_2SO_4 \longrightarrow H_2O + SO_2 + O] \times 10$$

$$P_4 + 10 O + 6H_2O \longrightarrow 4H_3PO_4$$

$$P_4 + 10H_2SO_4 \longrightarrow 4H_3PO_4 + 10SO_2 + 4H_2O$$

It reduces solutions of copper, silver and gold salts to corresponding metals.

 $P_4 + 10CuSO_4 + 16H_2O \longrightarrow 10Cu + 4H_3PO_4 + 10H_2SO_4$ When the solution is heated, cuprous phosphide is formed.

$$3P_4 + 12CuSO_4 + 24H_2O \xrightarrow{\text{Heat}} 4Cu_3P + 8H_3PO_3 + 12H_2SO_4$$
  
 $P_4 + 20AgNO_3 + 16H_2O \longrightarrow 20Ag + 4H_3PO_4 + 20HNO_3$ 

(xv) When heated in inert atmosphere at 240°C, it changes into red variety.

Yellow P 
$$\xrightarrow{240-250^{\circ}\text{C}}$$
 Red P

**Structure:** The vapour density of white phosphorus between 500-700°C, is 62 which corresponds to the molecular formula P<sub>4</sub>. The four phosphorus atoms lie at the corners of a regular tetrahedron. Each phosphorus atom is linked to each of the other three atoms by covalent bonds. The P—P bond length is equal to 2.21 Å. The bond angle is equal to 60° which suggests that the molecule is under strain and hence active in nature.

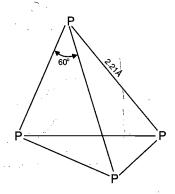

Fig. 10.10

## Red phosphorus

**Preparation:** Red phosphorus is obtained by heating yellow phosphorus, between 240-250°C, in presence of an inert gas for several hours. The heating is done in an egg shaped iron vessel provided with a upright tube closed by safety valve. The thermometers placed in iron tubes help to regulate the temperature.

Yellow phosphorus is taken in egg shaped vessel and air inside is replaced by coal gas or carbon dioxide. A trace of iodine is added which helps in the transformation. The vessel is carefully heated to 250°C. The temperature is not allowed to rise above 250°C otherwise the reaction goes out of control. In case the pressure inside the vessel becomes too high the safety valve is lifted to allow the escape of some vapours. The heating is done for several days. Red phosphorus obtained is powdered. It possesses yellow phosphorus as impurity. This is removed by boiling with caustic soda solution. Red phosphorus is not affected by caustic soda and remains undissolved. This is thoroughly washed with water and finally dried. Red phosphorus is much less reactive than white phosphorus and can be stored in the presence of air.

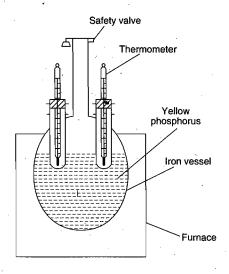

Fig. 10.11

**Properties:** (a) It is dark red powder with specific gravity 2.1.

- (b) It is odourless and non-poisonous in nature.
- (c) It is insoluble in water as well as in carbon disulphide.
- (d) It does not show phosphorescence.
- (e) It sublimes in absence of air at 290°C.
- (f) Its ignition temperature is high, i.e., 260°C.
- (g) Chemically, it is not active in nature. It burns when heated above 260°C to form phosphorus pentoxide.
  - (h) It does not react with caustic alkalies.
- (i) It combines with halogens, sulphur and metals when heated.

$$\begin{array}{c} 2P + 5Cl_2 \xrightarrow{\quad Heat \quad} 2PCl_5 \\ 2P + 3S \xrightarrow{\quad Heat \quad} P_2S_3 \\ P + 3Na \xrightarrow{\quad Heat \quad} Na_3P \end{array}$$

(j) It changes to white phosphorus when it is vaporised and the vapours are condensed.

**Structure of red phosphorus:** The exact structure of red phosphorus is not yet known. It is regarded as a polymer consisting of chains of P<sub>4</sub> tetrahedral linked together possibly in the manner as shown in Fig. 10.12.

Fig. 10.12 Proposed molecular structure of red phosphorus

#### COMPARISON BETWEEN WHITE AND RED PHOSPHORUS

Property	White phosphorus	Red phosphorus
1. Physical state	Soft waxy solid.	Brittle powder.
2. Colour	White when pure.	Red.
	Attains yellow colour on standing.	
3. Odour	Garlic	Odourless.
4. Specific gravity	1.8	2.1
5. Melting point	44°C	Sublimes in absence of air at 290°C.
6. Ignition temperat	ture Low, 30°C	High, 260°C.
7. Solubility in wat	er Insoluble.	Insoluble.
8. Solubility in CS2	Soluble.	Insoluble.
9. Physiological act	ion Poisonous.	Non-poisonous.
10. Chemical activity	y Very active.	Less active.
11. Stability	Unstable.	Stable.
12. Phosphorescence	Glows in dark.	Does not glow in dark.
13. Burning in air	Forms P <sub>4</sub> O <sub>10</sub> .	Forms P <sub>4</sub> O <sub>10</sub> .
14. Reaction with Na	OH Evolves phosphine.	No action.
15. Action of Cl <sub>2</sub>	Combines spontaneously to form PCl <sub>3</sub> and PCl <sub>5</sub> .	
16. Reaction with HNO <sub>3</sub>	hot Forms H <sub>3</sub> PO <sub>4</sub> .	Forms H <sub>3</sub> PO <sub>4</sub> .
17. Molecular formu	la P₄	Complex polymer.

**Uses of phosphorus:** (i) Red phosphorus is largely used in the match industry. It is relatively nontoxic and is used in the striking surface of safety matches. Red phosphorus or scarlet phosphorus is preferred to yellow variety.

- (ii) Yellow phosphorus is used as a rat poison.
- (iii) Red phosphorus is used for the preparation of HBr and HI.
- (iv) Radioactive phosphorus (P<sup>32</sup>) is used in the treatment of leukemia and other blood disorders.
- (v) It is used for making incendiary bombs and smoke screens.
- (vi) It is used in the manufacture of phosphor bronze, an alloy of phosphorus, copper and tin.
- (vii) It is used in the manufacture of compounds like hypophosphites (medicine), phosphorus chlorides employed in industry, calcium phosphide used in making Holme's signals and orthophosphoric acid.

## 10.7 COMPOUNDS OF PHOSPHORUS

## 1. Phosphine, PH<sub>3</sub>

It is analogous to ammonia. It was discovered by Gengembre in 1783. It is also known as **hydrogen phosphide** or **phosphoretted hydrogen.** 

**Laboratory preparation:** It is prepared by boiling yellow phosphorus with a concentrated solution of sodium hydroxide in an inert atmosphere.

$$\begin{array}{c} P_4 \,+\, 3NaOH \,+\, 3H_2O \longrightarrow & 3NaH_2PO_2 \quad + \ PH_3 \\ \text{Sodium hypophosphite} \end{array}$$

Besides  $PH_3$ , small amounts of hydrogen  $(H_2)$  and phosphorus dihydride  $(P_2H_4)$  are also formed.

$$P_4 + 4NaOH + 4H_2O \longrightarrow 4NaH_2PO_2 + 2H_2$$
  
 $3P_4 + 8NaOH + 8H_2O \longrightarrow 8NaH_2PO_2 + 2P_2H_4$ 

A concentrated solution of sodium hydroxide is taken in a round bottom flask. Few pieces of yellow phosphorus are

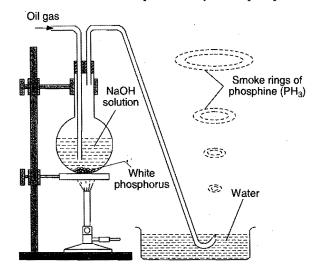

Fig. 10.13

dropped into it. Coal gas, oil gas or carbon dioxide is then bubbled through the flask to displace the air from the apparatus. The flask is then heated.  $PH_3$  is evolved. It is driven out along with a current of inert gas. As soon as the bubbles of the gas come in contact with air, they catch fire spontaneously forming rings of smoke known as vortex rings. This combustion is due to the presence of highly inflammable phosphorus dihydride  $(P_2H_4)$ .

2P<sub>2</sub>H<sub>4</sub> + 7O<sub>2</sub> 
$$\longrightarrow$$
 4HPO<sub>3</sub> + 2H<sub>2</sub>O Metaphosphoric

P<sub>2</sub>H<sub>4</sub> can be removed from phosphine by the following methods:

- (i) By passing the evolved gas through a freezing mixture which condenses P<sub>2</sub>H<sub>4</sub>.
- (ii) By passing the gas through HI. PH<sub>3</sub> is absorbed forming phosphonium iodide. This on treatment with caustic potash gives pure phosphine.

$$PH_4I + KOH \longrightarrow KI + H_2O + PH_3$$

**Note:** Pure phosphine can be obtained by using alcoholic potassium hydroxide in place of aqueous NaOH solution. Phosphine can also be prepared by the application of following reactions:

(i) By heating phosphorus acid.

$$4H_3PO_3 \longrightarrow 3H_3PO_4 + PH_3$$

(ii) By treating phosphonium iodide with 30% KOH solution.

$$PH_4I + KOH \longrightarrow KI + H_2O + PH_3$$

The evolved gas is first passed through HCl (decomposes P<sub>2</sub>H<sub>4</sub>) and then through NaOH (HI absorbed). This gives pure PH<sub>3</sub>.

(iii) By treating aluminium phosphide with dilute H<sub>2</sub>SO<sub>4</sub>.

$$2AIP + 3H_2SO_4 \longrightarrow AI_2(SO_4)_3 + 2PH_3$$

(iv) By doing hydrolysis of calcium phosphide with water or dil. HCl.

$$Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$$

## Physical properties:

- (a) It is a colourless gas having unpleasant garlic-like odour or rotten fish odour.
  - (b) It is heavier than air and sparingly soluble in water.
  - (c) It liquefies at -89°C and solidifies at -134°C.
  - (d) It is poisonous in nature.

#### Chemical properties:

(a) **Decomposition:** When heated out of contact of air to 440°C or when electric sparks are passed through, phosphine decomposes into red phosphorus and hydrogen.

$$4PH_3 \longrightarrow P_4 + 6H_2$$

**(b)** Combustibility: A pure sample of phosphine is not spontaneously inflammable. It burns in air or oxygen when heated at 150°C.

$$2PH_3 + 4O_2 \longrightarrow P_2O_5 + 3H_2O$$

The spontaneous inflammability of phosphine at the time of preparation is due to the presence of highly inflammable phosphorus dihydride, P<sub>2</sub>H<sub>4</sub>. This property is used in making

Holme's signal. A mixture of calcium carbide and calcium phosphide is placed in metallic containers. Two holes are made and the container is thrown into the sea. Water enters and produces acetylene and phosphine respectively. The gaseous mixture catches fire spontaneously due to the presence of  $P_2H_4$ . The acetylene produces a bright luminous flame which serves as a signal to the approaching ship.

**(c) Action of chlorine:** Phosphine burns in the atmosphere of chlorine and forms phosphorus pentachloride.

$$PH_3 + 4Cl_2 \longrightarrow PCl_5 + 3HCl$$

(d) Basic nature: Phosphine is neutral to litmus. However, it is a weak base, even weaker than ammonia. It reacts with HCl, HBr or HI to form phosphonium compounds.

$$PH_3 + HCl \longrightarrow PH_4Cl$$
 (Phosphonium chloride)  
 $PH_3 + HBr \longrightarrow PH_4Br$  (Phosphonium bromide)  
 $PH_3 + HI \longrightarrow PH_4I$  (Phosphonium iodide)

(e) Action of nitric acid: In contact with nitric acid phosphine begins to burn.

$$[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 8$$

$$2PH_3 + 8O \longrightarrow P_2O_5 + 3H_2O$$

$$2PH_3 + 16HNO_3 \longrightarrow P_2O_5 + 16NO_2 + 11H_2O$$

(f) Addition compounds: It forms addition compounds with anhydrous  $AlCl_3$  and  $SnCl_4$ .

$$AlCl_3 + 2PH_3 \longrightarrow AlCl_3 \cdot 2PH_3$$
  
 $SnCl_4 + 2PH_3 \longrightarrow SnCl_4 \cdot 2PH_3$ 

When PH<sub>3</sub> is passed through cuprous chloride solution in HCl, it forms an addition compound.

$$Cu_2Cl_2 + 2PH_3 \longrightarrow 2CuCl \cdot PH_3$$

**(g) Formation of phosphides:** (i) When phosphine is passed through copper sulphate solution, a black precipitate of cupric phosphide is formed.

$$3\text{CuSO}_4 + 2\text{PH}_3 \longrightarrow \text{Cu}_3\text{P}_2 + 3\text{H}_2\text{SO}_4$$

(ii) A black precipitate of silver phosphide is formed when phosphine is circulated through silver nitrate solution.

$$3AgNO_3 + PH_3 \longrightarrow Ag_3P + 3HNO_3$$

(iii) When absorbed in mercuric chloride solution, mercuric phosphide is formed.

$$3HgCl_2 + 2PH_3 \longrightarrow Hg_3P_2 + 6HCl$$

(h) The mixture of  $PH_3$  and  $N_2O$  or  $PH_3$  and NO explodes in presence of electric spark.

$$PH_3 + 4N_2O \longrightarrow H_3PO_4 + 4N_2$$

**Structure of phosphine:** Phosphine is a covalent molecule. It has pyramidal structure like ammonia.

The bond angle H—P—H is 93°.

Uses: (i) For making Holme's signals.

- (ii) For making smoke screens.
- (iii) For making metallic phosphides.

#### **COMPARISON OF PHOSPHINE AND AMMONIA**

Property	Ammonia	Phosphine
1. Physical state	Colourless gas.	Colourless gas.
2. Odour	Characteristic pungent smell.	Unpleasant odour of rotten fish.
3. Molecular formula	NH <sub>3</sub>	PH <sub>3</sub>
4. Solubility	Highly soluble in water.	Sparingly soluble in water.
5. Density	Lighter than air.	Heavier than air.
<ol><li>Physiological action</li></ol>	Non-poisonous.	Poisonous.
7. Stability	Decomposes at 1300°C.	Decomposes at 440°C.
8. Combustibility	It burns in oxygen.	It burns with white bright flame.
	$4NH_3 + 5O_2 \longrightarrow 4NO + 6H_2O$	$2PH_3 + 4O_2 \longrightarrow P_2O_5 + 3H_2O$
<ol><li>Basic character</li></ol>	Basic in nature. Forms ammonium salts with acids.	Weakly basic. Forms phosphonium salts with HCl, HBr and
	$NH_3 + HC1 \longrightarrow NH_4C1$	HI.
		$PH_3 + HCl \longrightarrow PH_4C1$
10. Stability of salts	Fairly stable.	Less stable.
11. Action of chlorine	Forms N <sub>2</sub> , NCl <sub>3</sub> and NH <sub>4</sub> Cl.	Forms PCl <sub>3</sub> and PCl <sub>5</sub> .
12. Action of AgNO <sub>3</sub>	Forms soluble complex, Ag(NH <sub>3</sub> ) <sub>2</sub> NO <sub>3</sub> .	Forms black precipitate Ag <sub>3</sub> P.
<ol> <li>Action of CuSO<sub>4</sub></li> </ol>	Forms soluble complex of blue colour, Cu(NH <sub>3</sub> ) <sub>4</sub> SO <sub>4</sub> .	Forms black precipitate of copper phosphide, Cu <sub>3</sub> P <sub>2</sub> .
<ol><li>Hydrogen bonding</li></ol>	Present.	Absent.
15. Solvent property	Ammonia is a good solvent for many substances.	It does not act as a solvent.
16. Action of hot sodium	Forms sodamide.	Forms phosphide.
	$2Na + 2NH_3 \longrightarrow 2NaNH_2 + H_2$	$6Na + 2PH_3 \longrightarrow 2Na_3P + 3H_2$
17. Structure	Pyramidal.	Pyramidal.
	Bond angle H—N—H = 107°	Bond angle H—P—H = 93°

## 2. Oxides of Phosphorus

Phosphorus forms three important oxides. These exist in dimeric forms.

- (i) Phosphorus trioxide, P<sub>2</sub>O<sub>3</sub> or P<sub>4</sub>O<sub>6</sub>
- (ii) Phosphorus tetroxide, P<sub>2</sub>O<sub>4</sub> or P<sub>4</sub>O<sub>8</sub>
- (iii) Phosphorus pentoxide, P<sub>2</sub>O<sub>5</sub> or P<sub>4</sub>O<sub>10</sub>

## (i) Phosphorus trioxide, P<sub>4</sub>O<sub>6</sub>

It is formed by burning phosphorus in limited supply of air.

$$P_4 + 3O_2 \longrightarrow P_4O_6$$

The pentoxide, formed in small amount, is removed by passing through glass wool. The vapours of trioxide pass through the glass wool and are condensed in a receiver cooled by a freezing mixture.

Vapours of phosphorus at low pressure react with  $N_2O$  at  $600^{\circ}C$ , to, form  $P_2O_3$ .

$$P_4 + 6N_2O \xrightarrow{600^{\circ}C} 2P_2O_3 + 6N_2$$

Properties: (a) It is a waxy solid having garlic odour.

- (b) It is poisonous in nature.
- (c) It is soluble in benzene or chloroform.
- (d) When heated above 210°C, it forms red phosphorus and another oxide, P<sub>4</sub>O<sub>8</sub>.

$$4P_4O_6 \longrightarrow 3P_4O_8 + 4P$$
Phosphorus
tetroxide

When heated at about 440°C, it dissociates to phosphorus dioxide.

$$2P_2O_3 \longrightarrow 3PO_2 + P$$

(e) In contact with air, it is oxidised to phosphorus pentoxide.

$$P_4O_6 + 2O_2 \longrightarrow P_4O_{10}$$

(f) It burns in chlorine forming oxy-chlorides.

$$\begin{array}{ccccc} P_4O_6 \ + \ 4Cl_2 \longrightarrow & 2POCl_3 \ + & 2PO_2Cl \\ & Phosphorus & Metaphosphorus \\ & oxy-chloride & oxy-chloride \end{array}$$

(g) In cold water, it dissolves slowly forming phosphorus acid.

$$P_4O_6 + 6H_2O(cold) \longrightarrow 4H_3PO_3$$

With hot water, a violent reaction occurs forming orthophosphoric acid and phosphine.

$$P_4O_6 + 6H_2O(hot) \longrightarrow 3H_3PO_4 + PH_3$$

The above reaction is actually the conversion of phosphorus acid into orthophosphoric acid and phosphine.

$$4H_3PO_3 \longrightarrow 3H_3PO_4 + PH_3$$

This oxide is known as acid anhydride of phosphorus acid.

Structure of phosphorus trioxide: Its vapour density corresponds to the formula  $P_4O_6$ . In the molecule, the phosphorus atoms lie at tetrahedral positions with respect to each other and the 6 oxygen atoms are inserted in between them (Fig. 10.14). Each phosphorus atom is covalently bonded

to three oxygen atoms and each oxygen atom is bonded to two phosphorus atoms. The bond length P—O is 1.638 Å.

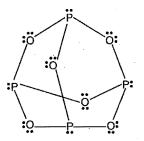

Fig. 10.14

It has 6 P—O—P bonds, 12 sigma bonds and 16 lone pairs of electrons (one lone pair on each P atom and two lone pairs of electrons on each oxygen atom).

## (ii) Phosphorus pentoxide, P<sub>4</sub>O<sub>10</sub>

It is prepared by heating phosphorus in a free supply of air or oxygen.

$$P_4 + 5O_2 \longrightarrow P_4O_{10}$$

It is further purified by sublimation.

Phosphorus burns in CO2 at 100°C to form P2O5.

$$2P + 5CO_2 \longrightarrow P_2O_5 + 5CO$$

**Properties:** (a) It is a white crystalline compound.

- (b) It is odourless when pure. The usual garlic odour is due to presence of small amount of  $P_4O_6$  as impurity.
  - (c) It is a white solid that sublimes at 360°C.
- (d) It has great affinity for water. The final product is orthophosphoric acid. It is, therefore, termed phosphoric anhydride.

i.e., 
$$P_4O_{10} + 6H_2O \longrightarrow 4H_3PO_4$$

It is, thus, used as a powerful dehydrating or drying agent. It removes water from inorganic and organic compounds like H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub>, RCOOH, RCONH<sub>2</sub>, etc.

$$2H_2SO_4 + P_4O_{10} \longrightarrow 2SO_3 + 4HPO_3$$

$$4HNO_3 + P_4O_{10} \longrightarrow 2N_2O_5 + 4HPO_3$$

$$4CH_3COOH + P_4O_{10} \longrightarrow 2(CH_3CO)_2O + 4HPO_3$$

$$2CH_3CONH_2 + P_4O_{10} \longrightarrow 2CH_3CN + 4HPO_3$$

It also chars wood, paper, sugar, etc.

(e) When heated strongly with carbon, it forms red phosphorus.

(f) When fused with basic oxides, it forms phosphates.

$$6CaO + P_4O_{10} \longrightarrow 2Ca_3(PO_4)_2$$

(g) 30%  $H_2O_2$  react on  $P_2O_5$  in acetonitrile solution at low temperature to form peroxy monophosphoric acid.

$$P_2O_5 + 2H_2O_2 + H_2O \longrightarrow 2H_3PO_5$$

(h) Mixture of  $P_2O_5$  and  $O_2$  in vapour state combine in presence of electric discharge to form  $P_2O_6$  called phosphorus peroxide.

$$P_2O_5 + \frac{1}{2}O_2 \longrightarrow P_2O_6$$

**Uses:** (i) It is the most effective drying or dehydrating agent below 100°C.

(ii) It is used to manufacture phosphoric acid, an oxoacid. **Structure of phosphorus pentoxide:** Its vapour density corresponds to formula P<sub>4</sub>O<sub>10</sub>. The structure is similar

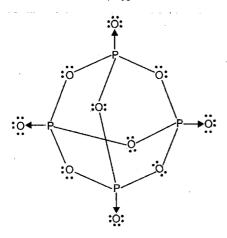

Fig. 10.15

to  $P_4O_6$  (Fig. 10.14) with a difference that each phosphorus atom is linked with an additional oxygen atom with the help of a coordinate linkage involving a lone pair of electrons present on each phosphorus atom (Fig. 10.15).

It has 16 sigma bonds,  $4\pi$  bonds and 24 lone pairs of electrons on oxygen atoms.

## 3. Oxyacids of Phosphorus

Phosphorus forms a number of oxyacids. Common oxyacids are given below:

Name of oxyacid	Formula	Basicity	Oxidation state of P
Hypophosphorus acid	H <sub>3</sub> PO <sub>2</sub>	1.	+1
Phosphorus acid	H <sub>3</sub> PO <sub>3</sub>	2	+3
Orthophosphoric acid	H <sub>3</sub> PO <sub>4</sub>	3	+5
Metaphosphoric acid	HPO <sub>3</sub>	1	+5
Hypophosphoric acid	$H_4P_2O_6$	4	+4
Pyrophosphoric acid	H <sub>4</sub> P <sub>2</sub> O <sub>7</sub>	4	+5

All these acids contain phosphorus atom/atoms linked tetrahedrally to four other atoms or groups. Each of them has at least one  $P \rightarrow O$  unit and one  $P \rightarrow OH$  group. The OH group is ionisable but H atom linked directly to P is non-ionisable. Thus, the number of OH groups present decides the basicity of the acid.

## (i) Hypophosphorus acid, H<sub>3</sub>PO<sub>2</sub>

**Preparation:** When yellow phosphorus is boiled with baryta solution, barium hypophosphite is formed which is filtered off.

The barium salt is treated with calculated quantity of sulphuric acid. The insoluble barium sulphate is filtered out and hypophosphorus acid is obtained in the filtrate. The filtrate when evaporated leaves the syrupy mass which can be crystallised by careful cooling below  $0^{\circ}$ C.

$$3Ba(OH)_2 + 8P + 6H_2O \longrightarrow 3Ba(H_2PO_2)_2 + 2PH_3$$

Barium hypophosphite

**Properties:** (a) It is a colourless crystalline solid. It melts at 26.3°C. It is soluble in water.

(b) It is a monobasic acid. It ionises as:

$$H_3PO_2 \rightleftharpoons H^+ + H_2PO_2^-$$
;  $K_a = 10^{-2} \text{ M}$ 

Its salts are known as hypophosphites.

(c) When strongly heated, it evolves phosphine.

$$2H_3PO_2 \longrightarrow H_3PO_4 + PH_3$$

- (d) It acts as a reducing agent.
- (i) It precipitates silver and gold from their solutions.

$$H_3PO_2 + 2H_2O \longrightarrow H_3PO_4 + 4H$$
  
 $[AgNO_3 + H \longrightarrow Ag + HNO_3] \times 4$ 

$$4AgNO_3 + H_3PO_2 + 2H_2O \longrightarrow 4Ag + H_3PO_4 + 4HNO_3$$

(ii) Mercuric chloride is reduced to mercurous chloride and finally to metallic mercury.

$$\begin{array}{c} H_3PO_2 + 2H_2O \longrightarrow H_3PO_4 + 4H \\ 2HgCl_2 + 2H \longrightarrow Hg_2Cl_2 + 2HCl \\ Hg_2Cl_2 + 2H \longrightarrow 2Hg + 2HCl \\ \hline 2HgCl_2 + H_3PO_2 + 2H_2O \longrightarrow 2Hg + H_3PO_4 + 4HCl \end{array}$$

(iii) Copper sulphate is reduced to cuprous hydride.  $4\text{CuSO}_4 + 3\text{H}_2\text{PO}_2 + 6\text{H}_2\text{O} \longrightarrow 2\text{Cu}_2\text{H}_2 + 3\text{H}_3\text{PO}_4 + 4\text{H}_2\text{SO}_4$ 

(iv) Chlorine or iodine is reduced to hydracid.

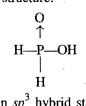

$$H_3PO_2 + 2H_2O \longrightarrow H_3PO_4 + 4H$$

$$4H + 2Cl_2 \longrightarrow 4HCl$$

$$H_3PO_2 + 2H_2O + 2Cl_2 \longrightarrow H_3PO_4 + 4HCl$$

**Uses:** Some of its salts such as sodium, potassium and calcium hypophosphites are used in medicine as nerve tonics.

**Structure:**  $H_3PO_2$  is a monobasic acid, *i.e.*, it has only one ionisable hydrogen atom or one OH group is present. It is given the following structure:

Phosphorus lies in  $sp^3$  hybrid state.

## (ii) Phosphorus acid, H<sub>3</sub>PO<sub>3</sub>

**Preparation:** (i) It is obtained by dissolving phosphorus trioxide in water.

$$P_4O_6 + 6H_2O \longrightarrow 4H_3PO_3$$

(ii) It is also obtained by hydrolysis of phosphorus trichloride.

$$PCl_3 + 3H_2O \longrightarrow H_3PO_3 + 3HCl$$

Chlorine is passed over molten white phosphorus under water when phosphorus trichloride formed undergoes hydrolysis.

$$2P + 3Cl_2 \longrightarrow 2PCl_3$$

The solution is heated until the temperature becomes 180°C. On cooling crystals of phosphorus acid are obtained.

**Properties:** (a) It is colourless crystalline compound. It melts at 73°C. It is highly soluble in water.

(b) When heated, it forms orthophosphoric acid and phosphine.

$$4H_3PO_3 \xrightarrow{200^{\circ}C} 3H_3PO_4 + PH_3$$

(c) It is a strong acid. It is dibasic in nature.

$$H_3PO_3 \rightleftharpoons H^+ + H_2PO_3^- \rightleftharpoons 2H^+ + HPO_3^-$$
  
 $K_1 = 10^{-1} ; K_2 = 2 \times 10^{-7}$ 

It thus forms two series of salts such as NaH<sub>2</sub>PO<sub>3</sub> and Na<sub>2</sub>HPO<sub>3</sub> known as primary phosphites and secondary phosphites respectively.

(d) It acts as a strong reducing agent. The potential equation is:

$$H_3PO_3 + H_2O \longrightarrow H_3PO_4 + 2H$$

It reduces CuSO<sub>4</sub> to Cu, AgNO<sub>3</sub> to Ag, HgCl<sub>2</sub> to Hg<sub>2</sub>Cl<sub>2</sub>, I<sub>2</sub> to HI and acidified KMnO<sub>4</sub> solution.

$$CuSO_4 + 2H \longrightarrow Cu + H_2SO_4$$

$$AgNO_3 + H \longrightarrow Ag + HNO_3$$

$$2HgCl_2 + 2H \longrightarrow Hg_2Cl_2 + 2HCl$$

$$I_2 + 2H \longrightarrow 2HI$$

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O$$

$$[H_3PO_3 + O \longrightarrow H_3PO_4] \times 5$$

$$2KMnO_4 + 3H_2SO_4 + 5H_3PO_3 \longrightarrow K_2SO_4 + 2MnSO_4 + 5H_3PO_4 + 3H_2O_4$$

**Structure:** It is dibasic acid, *i.e.*, two hydrogen atoms are ionisable or two hydroxyl groups are present. Thus, the structure is:

The phosphorus lies in  $sp^3$  hybrid state.

## (iii) Orthophosphoric acid, H<sub>3</sub>PO<sub>4</sub>

This acid is commonly called as phosphoric acid.

**Preparation:** (i) It is formed when phosphorus pentoxide is boiled with hot water.

$$P_4O_{10} + 6H_2O \longrightarrow 4H_3PO_4$$

(ii) Orthophosphoric acid is also formed when PCl<sub>5</sub> (phosphorus pentachloride) is boiled with water.

$$PCl_5 + 4H_2O \longrightarrow H_3PO_4 + 5HCl$$

(iii) Laboratory preparation: The best method for its preparation in the laboratory is to heat red phosphorus with concentrated nitric acid in a flask with a reflux condenser.

$$P + 5HNO_3 \longrightarrow H_3PO_4 + H_2O + 5NO_2$$

The reaction is usually carried out in presence of a crystal of iodine. The iodine acts as a catalyst.

$$P + 3I \longrightarrow PI_{3}$$

$$PI_{3} + 3H_{2}O \longrightarrow H_{3}PO_{3} + 3HI$$

$$3HI + 3HNO_{3} \longrightarrow 3H_{2}O + 3NO_{2} + 3I$$

$$H_{3}PO_{3} + 2HNO_{3} \longrightarrow H_{3}PO_{4} + H_{2}O + 2NO_{2}$$

$$P + 5HNO_{3} \longrightarrow H_{3}PO_{4} + 5NO_{2} + H_{2}O$$

The solution is concentrated till it becomes syrupy at about  $170^{\circ}$ C. It is cooled over conc.  $H_2SO_4$  in vacuum desiccator when crystals of orthophosphoric acid are formed.

**Manufacture:** It is prepared on large scale from bone ash or phosphorite mineral.

(a) By decomposing calcium phosphate present in bone ash or phosphorite mineral with conc. H<sub>2</sub>SO<sub>4</sub>.

$$Ca_3(PO_4)_2 + 3H_2SO_4 \longrightarrow 3CaSO_4 + 2H_3PO_4$$

On standing calcium sulphate settles down and the clear supernatant liquid separates out. The liquid is concentrated when about 85% concentrated orthophosphoric acid is obtained.

(b) The bone ash is dissolved in minimum amount of nitric acid and lead acetate is added as to precipitate lead phosphate. The lead salt is then decomposed by passing  $H_2S$ .

$$Pb_3(PO_4)_2 + 3H_2S \longrightarrow 3PbS + 2H_3PO_4$$
Insoluble Solution

(c) Bone ash or calcium phosphate is converted into phosphorus pentoxide when heated with silica in electric furnace.

 $2Ca_3(PO_4)_2 + 6SiO_2 \longrightarrow 6CaSiO_3 + P_4O_{10}$   $P_4O_{10}$  is then dissolved in hot water.

$$P_4O_{10} + 6H_2O \longrightarrow 4H_3PO_4$$

**Properties:** (a) It is a transparent deliquescent crystalline solid. It melts at 42.3°C. It absorbs water and forms colourless syrupy mass. It is highly soluble in water.

It is usually sold as an aqueous solution.

(b) **Heating effect**: When heated at 250°C, it is converted into pyrophosphoric acid.

$$2H_3PO_4 \xrightarrow{250^{\circ}C} H_4P_2O_7 + H_2O$$

On further heating, it is converted into metaphosphoric acid.

$$H_3PO_4 \xrightarrow{\text{Heat } \cdot} HPO_3 + H_2O$$

or

$$H_4P_2O_7 \xrightarrow{\text{Heat}} 2HPO_3 + H_2O$$

When strongly heated at red heat, it forms P<sub>4</sub>O<sub>10</sub>.

$$4H_3PO_4 \longrightarrow P_4O_{10} + 6H_2O$$

(c) Acidic nature: It is a tribasic acid, *i.e.*, all the three hydrogen atoms are ionisable. It forms three series of salts.

$$H_3PO_4 \Longrightarrow H^+ + H_2PO_4^- \Longrightarrow 2H^+ + HPO_4^{2-} \Longrightarrow 3H^+ + PO_4^{3-}$$
 $Na_4PO_4 \longrightarrow Na_2HPO_4 \longrightarrow Na_3PO_4$ 
(Primary salt) (Secondary salt) (Normal or tertiary salt)

Possible sodium salts are sodium dihydrogen phosphate (NaH<sub>2</sub>PO<sub>4</sub>), disodium hydrogen phosphate (Na<sub>2</sub>HPO<sub>4</sub>), and trisodium phosphate (Na<sub>3</sub>PO<sub>4</sub>).

Primary salt on heating forms a salt of metaphosphoric acid.

$$\begin{array}{c|c} NaH_2PO_4 & \xrightarrow{\quad Heat \quad} NaPO_3 & + & H_2O \\ \hline Sodium & dihydrogen & Sodium & meta-phosphate \\ \hline phosphate & phosphate \\ \end{array}$$

Secondary salt on heating forms a salt of pyrophosphoric acid.

Normal salt is not affected by heating.

In case, ammonium ion is present in the salt it behaves as hydrogen.

$$2MgNH_4PO_4 \xrightarrow{Heat} Mg_2P_2O_7 + 2NH_3 + H_2O$$
 $NaNH_4HPO_4 \xrightarrow{Heat} NaPO_3 + NH_3 + H_2O$ 

(d) **Reaction with AgNO<sub>3</sub>**: A yellow precipitate of silver phosphate is formed.

$$3AgNO_3 + H_3PO_4 \longrightarrow Ag_3PO_4 + 3HNO_3$$
  
Yellow ppt.

(e) **Reaction with BaCl<sub>2</sub>:** A white precipitate of barium phosphate is formed in neutral or alkaline solution.

$$3BaCl_2 + 2H_3PO_4 \longrightarrow Ba_3(PO_4)_2 + 6HCl$$
White ppt.

(f) **Reaction with bromides and iodides:** Hydrobromic and hydroiodic acids are liberated from bromides and iodides respectively. This is the laboratory preparation of HBr and HI.

$$3NaBr + H_3PO_4 \longrightarrow Na_3PO_4 + 3HBr$$
  
 $3NaI + H_3PO_4 \longrightarrow Na_3PO_4 + 3HI$ 

(g) **Reaction with magnesium salt:** Magnesium salts combine with orthophosphoric acid in presence of ammonium chloride and ammonium hydroxide to form a white precipitate of magnesium ammonium phosphate.

$$MgSO_4 + NH_4Cl + H_3PO_4 \longrightarrow Mg(NH_4)PO_4 + H_2SO_4 + HCl$$

This reaction is used to test Mg<sup>2+</sup> ion.

(h) On heating orthophosphoric acid in presence of nitric acid with ammonium molybdate, a canary yellow precipitate of ammonium phosphomolybdate is formed.

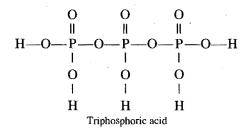

$$H_3PO_4 + 2IHNO_3 + 12(NH_4)_2MoO_4 \longrightarrow$$

$$(NH_4)_3PO_412MoO_3 + 21NH_4NO_3 + 12H_2O$$
Ammonium phosphomolybdate

This reaction is used to test  $PO_4^{3-}$  ion.

(i) Orthophosphoric acid, H<sub>3</sub>PO<sub>4</sub> undergoes condensation reaction to form other phosphoric acids. For example, two orthophosphoric acid molecules condense to form diphosphoric acid or pyrophosphoric acid.

Two series of these phosphoric acids exist (all having in the +5 oxidation state). One series consist of the linear polyphosphoric acids, which are acids with the general formula  $H_{n+2}P_nO_{3n+1}$  formed from linear chains of P—O bonds.

The other series consists of the metaphosphoric acids, which are acids with the general formula  $(HPO_3)_n$ . When a linear polyphosphoric acid chain is very long, the formula becomes  $(HPO_3)_n$ , with n very large, and the acid is called polymetaphosphoric acid.

Sodium triphosphate, Na<sub>5</sub>P<sub>3</sub>O<sub>10</sub>, one of the most commonly used polyphosphate, is manufactured by adding sufficient sodium carbonate to orthophosphoric acid to give a solution of the salts NaH<sub>2</sub>PO<sub>2</sub> and Na<sub>2</sub>HPO<sub>4</sub>. When this solution is sprayed into a hot kiln, the orthophosphate ions condense to give sodium triphosphate.

Uses: Orthophosphoric acid is used:

- (a) for making metaphosphoric and polyphosphoric acids.
- (b) for preparation of HBr and HI in the laboratory.
- (c) as a stabilizer for H<sub>2</sub>O<sub>2</sub>.
- (d) for soft drinks.
- (e) for manufacture of phosphate fertilizers.
- (f) Orthophosphoric acid as polyphosphates and metaphosphates are used in detergents, where they act as water softeners by complexing with metal ions in the water.

**Structure:** Orthophosphoric acid is a tribasic acid, *i.e.*, 3 hydroxyl groups are present. The structure of the acid is thus represented as:

Phosphorus atom lies in  $sp^3$  hybrid state.

## (iv) Pyrophosphoric acid, H<sub>4</sub>P<sub>2</sub>O<sub>7</sub>

**Preparation:** It is prepared by heating orthophosphoric acid at 250–260°C.

$$2H_3PO_4 \longrightarrow H_4P_2O_7 + H_2O$$

A pure sample of the acid is formed by heating an equimolecular mixture of orthophosphoric acid and phosphorus oxychloride.

$$5H_3PO_4 + POCl_3 \longrightarrow 3H_4P_2O_7 + 3HCl$$

On cooling at -10°C, crystals of the acid are obtained.

**Properties:** It is a white crystalline solid, soluble in water. In aqueous solution, it is converted into orthophosphoric acid.

$$H_4P_2O_7 + H_2O \longrightarrow 2H_3PO_4$$

On strong heating, it is converted into metaphosphoric acid.

$$H_4P_2O_7 \xrightarrow{\text{Red heat}} 2HPO_3 + H_2O$$

It is a tetrabasic acid and forms two series of salts.

$$H_4P_2O_7 + 2NaOH \longrightarrow Na_2H_2P_2O_7 + 2H_2O$$

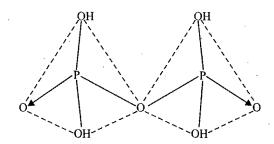

$$H_4P_2O_7\,+\,4NaOH \longrightarrow \,Na_4P_2O_7\,+\,4H_2O$$

It gives a white precipitate with AgNO<sub>3</sub>.

$$4AgNO_3 + H_4P_2O_7 \longrightarrow Ag_4P_2O_7 + 4HNO_3$$

**Structure:** It is a tetrabasic acid, *i.e.*, 4 hydroxyl groups are present. The structure follows directly from the fact that the acid can be prepared by removing one water molecule from two molecules of orthophosphoric acid.

Each phosphorus atom lies in tetrahedral environment. (sp<sup>3</sup> hybrid state.)

## (v) Metaphosphoric acid, HPO<sub>3</sub>

**Preparation:** It is prepared by heating orthophosphoric acid or pyrophosphoric acid or diammonium hydrogen orthophosphate.

$$H_3PO_4 \xrightarrow{600^{\circ}C} HPO_3 + H_2O;$$
 $H_4P_2O_7 \xrightarrow{600^{\circ}C} 2HPO_3 + H_2O$ 
 $(NH_4)_2HPO_4 \longrightarrow HPO_3 + 2NH_3 + H_2O$ 

It is also prepared by dissolving P<sub>2</sub>O<sub>5</sub> with small amount of water at 0°C.

$$P_2O_5 + H_2O \longrightarrow 2HPO_3$$

**Properties:** It is a transparent glassy solid. The acid is, therefore, known as glacial phosphoric acid. It dissolves in water with cracking sound. On boiling the aqueous solution, it is converted into orthophosphoric acid.

$$HPO_3 + H_2O \longrightarrow H_3PO_4$$

It reacts with AgNO<sub>3</sub> forming a white precipitate.

$$AgNO_3 + HPO_3 \longrightarrow AgPO_3 + HNO_3$$

BaCl<sub>2</sub> gives a white precipitate which is insoluble in acetic acid.

$$BaCl_2 + 2HPO_3 \longrightarrow Ba(PO_3)_2 + 2HCl$$

It forms salts with alkalies. The salts are called metaphosphates. Sodium metaphosphate when heated with metal oxides forms mixed phosphates. The mixed phosphates of heavy metals have characteristic colours; hence used in qualitative analysis.

Uses: It is used:

- (i) as a dehydrating agent.
- (ii) as a water softener (calgon) in the form of a polymer, (NaPO<sub>3</sub>)<sub>6</sub>.
  - (iii) in the manufacture of dental cements.

**Structure:** It is a monobasic acid, *i.e.*, it consists one OH group. As it is formed by dehydration of H<sub>3</sub>PO<sub>4</sub>, it can be represented as HO—P=O.

$$\begin{array}{c} OH \\ | \\ HO - P - OH \\ \downarrow \\ O \end{array} \xrightarrow{-H_2O} HO - P = O$$

Metaphosphoric acid or its salts are not present in the form of simple molecules but are often polymerised,  $(HPO_3)_n$ .

Structure of dimeric metaphosphoric acid may be given as:

Structure of trimeric metaphosphoric acid can be represented in cyclic form.

The polymerised form is represented as:

## 4. (i) Phosphorus Trichloride, PCl<sub>3</sub>

**Preparation:** It is formed when dry chlorine is passed over red or white phosphorus heated gently in a retort over a water bath. The vapours of trichloride are condensed in a receiver cooled in a freezing mixture.

$$P_4 + 6Cl_2 \longrightarrow 4PCl_3$$

**Properties:** It is colourless fuming liquid. It reacts violently with water forming phosphorus acid.

$$PCl_3 + 3HOH \longrightarrow H_3PO_3 + 3HCl$$

It reacts with concentrated H<sub>2</sub>SO<sub>4</sub> forming chloro-sulphonic acid.

$$4H_2SO_4 + 2PCl_3 \longrightarrow 2HSO_3Cl + P_2O_5 + 2SO_2 + 4HCl + H_2O$$
Chloro-sulphonic

or 
$$2H_2SO_4 + PCl_3 \longrightarrow HSO_3Cl + HPO_3 + SO_2 + 2HCl$$

It reacts with organic compounds containing hydroxyl group.

$$\begin{array}{c} 3C_2H_5OH + PCl_3 \longrightarrow 3C_2H_5Cl + H_3PO_3 \\ \text{Ethyl alcohol} & \text{Ethyl chloride} \end{array}$$

3CH<sub>3</sub>COOH + PCl<sub>3</sub> 
$$\longrightarrow$$
 3CH<sub>3</sub>COCl + H<sub>3</sub>PO<sub>3</sub>  
Acetic acid Acetyl chloride

$$3C_6H_5SO_2\cdot OH + PCl_3 \longrightarrow 3C_6H_5SO_2Cl + H_3PO_3$$
Benzene sulphonic
Benzene sulphonyl
chloride

It directly combines with Cl<sub>2</sub>, O<sub>2</sub> and S. This indicates that it is an unsaturated compound.

$$\begin{array}{c} PCl_3 + Cl_2 \longrightarrow PCl_5 \\ 2PCl_3 + O_2 \longrightarrow 2POCl_3 \\ PCl_3 + S \longrightarrow PSCl_3 \end{array}$$

It acts as a reducing agent.

$$PCl_3 + SO_2Cl_2 \longrightarrow PCl_5 + SO_2$$

$$PCl_3 + SO_3 \longrightarrow POCl_3 + SO_2$$

$$3PCl_3 + SOCl_2 \longrightarrow POCl_3 + PSCl_3 + PCl_5$$

$$3PCl_3 + S_2Cl_2 \longrightarrow PCl_5 + 2PSCl_3$$

It reacts with finely divided metals when hot.

$$12Ag + 4PCl_3 \longrightarrow 12AgCl + P_4$$
  
 $6Na + PCl_3 \longrightarrow 3NaCl + Na_3P$ 

**Uses:** It is used in the manufacture of  $POCl_3$  and in the preparation of organic compounds.

**Structure:** Its structure is similar to ammonia. P atom undergoes  $sp^3$  hybridization. In the tetrahedral configuration, one of the position is occupied by a lone pair. Thus, it is pyramidal in shape.

## (ii) Phosphorus Pentachloride, PCI<sub>5</sub>

**Preparation:** It is obtained by action of an excess of dry chlorine gas on phosphorus trichloride.

$$PCl_3 + Cl_2 \longrightarrow PCl_5$$

It may be obtained by the action of sulphuryl chloride (SO<sub>2</sub>Cl<sub>2</sub>) on phosphorus or phosphorus trichloride.

$$P_4 + 10SO_2Cl_2 \longrightarrow 4PCl_5 + 10SO_2$$
  
 $PCl_3 + SO_2Cl_2 \longrightarrow PCl_5 + SO_2$ 

**Properties:** It is almost colourless crystalline solid with pungent odour when pure. On heating it sublimes at 160°C. When heated it dissociates into PCl<sub>3</sub> and Cl<sub>2</sub>.

$$PCl_5 \Longrightarrow PCl_3 + Cl_2$$

It undergoes hydrolysis violently by water.

$$PCl_5 + H_2O \longrightarrow POCl_3 + 2HCl$$
  
 $PCl_5 + 4H_2O \longrightarrow H_2PO_4 + 5HCl$ 

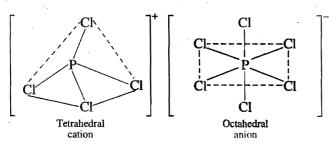

It reacts with hydroxy compounds and replaces hydroxyl groups to chlorine atoms.

$$\begin{array}{c} C_2H_5OH + PCl_5 \longrightarrow C_2H_5Cl + POCl_3 + HCl \\ CH_3COOH + PCl_5 \longrightarrow CH_3COCl + POCl_3 + HCl \\ SO(OH)_2 + 2PCl_5 \longrightarrow SO_2Cl_2 + 2POCl_3 + 2HCl \\ Sulphuric acid \\ \end{array}$$

Many metals are converted into chlorides when heated with PCl<sub>5</sub>.

$$PCl_5 + Zn \longrightarrow ZnCl_2 + PCl_3$$

**Uses:** It is used as chlorinating agent in organic chemistry. **Structure:** X-ray studies have revealed that solid PCl<sub>5</sub> consists of ionic lattices, *i.e.*, tetrahedral [PCl<sub>4</sub>]<sup>+</sup> cations and octahedral [PCl<sub>6</sub>]<sup>-</sup> anions. In vapour state, it has trigonal bipyramid shape in which P has gone  $sp^3d$  hybridization. (See page 99)

# 10.8 ARSENIOUS OXIDE OR ARSENIC TRIOXIDE

This is the most important compound of arsenic and is technically called as white arsenic.

**Preparation:** On a large scale, it is obtained by roasting arsenopyrite ore, FeAsS, in air.

$$2FeAsS + 5O_2 \longrightarrow As_2O_3 + Fe_2O_3 + 2SO_2$$

It is also formed when arsenic is heated in air or oxygen.

$$4As + 3O_2 \longrightarrow 2As_2O_3$$

**Properties:** (a) It is a white poisonous powder. A very small dose of 50 mg or so may prove fatal. It undergoes sublimation.

(b) It is sparingly soluble in water. It reacts with water to form arsenious acid. The oxide is, therefore, known as arsenious anhydride.

$$As_2O_3 + 3H_2O \longrightarrow 2H_3AsO_3$$

The acid is unstable and is known in solution. Its salts, known as arsenites, are quite stable.

(c) It is an amphoteric oxide.

$$As_2O_3 + 6NaOH \longrightarrow 2Na_3AsO_3 + 3H_2O$$
Sodium arsenite
$$As_2O_3 + 6HC1 \longrightarrow 2AsCl_3 + 3H_2O$$
Arsenic chloride

(d) When treated with hydrogen sulphide, arsenic sulphide (yellow precipitate) is formed.

$$As_2O_3 + 3H_2S \longrightarrow As_2S_3 + 3H_2O$$

(e) It acts as a reducing agent as it is changed to pentoxide (or arsenic acid,  $As_2O_5 + 3H_2O \longrightarrow 2H_3AsO_4$ )

(i) 
$$As_2O_3 + 2I_2 + 2H_2O \longrightarrow As_2O_5 + 4HI$$
  
(ii)  $[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 2$   
 $As_2O_3 + 2O \longrightarrow As_2O_5$   
 $As_2O_3 + 4HNO_3 \longrightarrow As_2O_5 + 4NO_2 + 2H_2O$   
(iii)  $[2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O] \times 2$ 

$$[As_2O_3 + 2O \longrightarrow As_2O_5] \times 5$$

$$4KMnO_4 + 6H_2SO_4 + 5As_2O_3 \longrightarrow$$

$$2K_2SO_4 + 4MnSO_4 + 5As_2O_5 + 6H_2O$$
(iv)
$$[H_2O_2 \longrightarrow H_2O + O] \times 2$$

$$As_2O_3 + 2O \longrightarrow As_2O_5$$

$$As_2O_3 + 2H_2O_2 \longrightarrow As_2O_5 + 2H_2O$$
(v)
$$[O_3 \longrightarrow O_2 + O] \times 2$$

$$As_2O_3 + 2O \longrightarrow As_2O_5$$

$$As_2O_3 + 2O \longrightarrow As_2O_5$$

$$As_2O_3 + 2O \longrightarrow As_2O_5$$

(f) It is reduced to arsenic by acidified stannous chloride.  $[SnCl_2 + 2HCl \longrightarrow SnCl_4 + 2H] \times 3$   $As_2O_3 + 6H \longrightarrow 2As + 3H_2O$  $As_2O_3 + 3SnCl_2 + 6HCl \longrightarrow 3SnCl_4 + 2As + 3H_2O$ 

- **Uses:** (i) It is used as a weed killer and as an insecticide.
- (ii) In very small doses, it is used as medicine and for killing rats.
  - (iii) It is used for making pyrex glass.
  - (iv) As a reducing agent in volumetric analysis.
  - (v) It is employed in dyeing and calicoprinting
  - (vi) It is used for preservation of hides and skins.

## 10 FERTILIZERS

For the normal and healthy growth of plants, more than twelve elements such as carbon, oxygen, hydrogen, nitrogen, phosphorus, potassium, calcium, magnesium, iron, zinc, manganese, molybdenum, sulphur, etc., are essential. These are called plant nutrients. Out of these elements, carbon, hydrogen, oxygen and a part of nitrogen are drawn from the inexhaustible air and water. The remaining elements including nitrogen are supplied by soil. Nitrogen, phosphorus and potassium are regarded as essential plant nutrients and are consumed in large quantities. Other elements are required in minute quantities by plants and are termed as secondary nutrients. The soil is never deficient in secondary nutrients. However, after a few years of continuous cultivation, the soil becomes poorer and poorer in materials supplying nitrogen, phosphorus and potassium to plants. If the soil is not compensated what it has lost in time, it would become less productive and ultimately infertile. Thus, in order to maintain soil fertility, it is necessary to add materials containing nitrogen, phosphorus and potassium in the form of manures. Manures are of two types:

- (1) Natural manures and (2) Artificial manures.
- 1. Natural manures: It includes animal waste such as blood, bones, horns, leather waste, fish scrap, excreta, night soil, sewage, sludge, tankage, guano, etc., and decayed plants such as cotton seed meal, wood or tobacco stem ashes, oil cakes and green growing plants buried in the soil, etc.
- 2. Chemical manures or artificial manures or fertilizers: These are chemical compounds containing nitrogen, phosphorus or potassium obtained by artificial means. These chemical compounds are generally called fertilizers. "The chemical substances which are added to the soil as to make up the deficiency of essential elements are called fertilizers".

Every chemical compound of nitrogen, phosphorus and potassium cannot be used as a fertilizer. The chemical substance which can be used as a fertilizer must have the following characteristics:

- (i) It must be soluble in water.
- (ii) It should be easily assimilated by plants.
- (iii) It should be fairly stable.

- (iv) It should not be injurious to plants.
- (v) It should not disturb pH of the soil.
- (vi) It should be cheap.

### Classification of fertilizers:

Fertilizers are classified according to the elements (N, P and K) which they supply to the soil:

- (i) Nitrogenous fertilizers
- (ii) Phosphatic fertilizers
- (iii) Potash fertilizers
- (iv) Phosphatic cum nitrogen fertilizers
- (v) NPK fertilizers.

## Nitrogenous Fertilizers

The important nitrogenous compounds used as fertilizers are:

- (i) Ammonium nitrate
- (ii) Ammonium sulphate,
- (iii) Calcium cyanamide,
- (iv) Calcium ammonium nitrate,
- (v) Basic calcium nitrate,
- (vi) Urea.

## (i) Ammonium nitrate

Ammonium nitrate is prepared from ammonia. Ammonia from the Haber process is burned in oxygen over a platinum catalyst to obtain niric oxide, NO;

$$4NH_3 + 5O_2 \longrightarrow 4NO + 6H_2O$$

The nitric oxide, reacts readily with oxygen from the air to form nitrogen dioxide, NO<sub>2</sub>;

$$2NO + O_2 \longrightarrow 2NO_2$$

NO<sub>2</sub> in turn reacts with water to yield nitric acid HNO<sub>3</sub> and nitrous acid, HNO<sub>2</sub>. The nitrous acid, being unstable, is decomposed with heat and the resulting nitric oxide, NO, can be volatilized and recycled,

$$2NO_2 + H_2O \longrightarrow HNO_3 + HNO_2$$
  
 $3HNO_2 \longrightarrow HNO_3 + H_2O + 2NO$ 

Additional ammonia then reacts with the nitric acid to produce ammonium nitrate  $(NH_4NO_3)$ ;

$$HNO_3 + NH_3 \longrightarrow NH_4NO_3$$

Solid ammonium nitrate should be **handled carefully** though pure ammonium nitrate is quite stable in farming operation, it is an oxidising agent and can explode on heating when mixed in bulk with reducing materials. Pure ammonium nitrate applied to the soil poses no explosive threat at all.

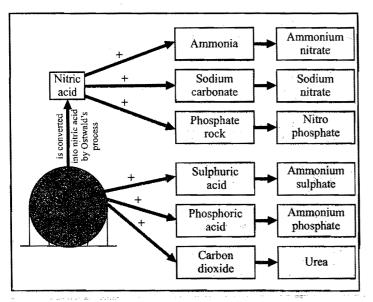

Fig. 10.16 Nitrogen fertilizers from anhydrous ammonia

## (ii) Ammonium sulphate, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>

The following two processes are used for its manufacture:

(a) Ammonia liquor obtained from dry distillation of coal: Ammonia liquor obtained during distillation of coal consists various ammonium compounds. In order to recover ammonia, the liquor is mixed with lime and heated in stills by steam. The mixture of ammonia and steam so produced is passed through a lead lined tank containing 60% H<sub>2</sub>SO<sub>4</sub>, when crystals of  $(NH_4)_2SO_4$  separate on cooling.

$$(NH_4)_2CO_3 + Ca(OH)_2 \longrightarrow CaCO_3 + 2NH_3 + 2H_2O$$
  
 $2NH_4Cl + Ca(OH)_2 \longrightarrow CaCl_2 + 2NH_3 + 2H_2O$ 

$$\begin{array}{c} \text{NH}_4\text{HS} \xrightarrow{\text{Heat}} \text{NH}_3 + \text{H}_2\text{S} \\ 2\text{NH}_3 + \text{H}_2\text{SO}_4 \longrightarrow (\text{NH}_4)_2\text{SO}_4 \end{array}$$

(b) Ammonia obtained from Haber process: The synthetic ammonia obtained from Haber process is also converted into ammonium sulphate by absorbing it in sulphuric acid.

## Sindri process

Ammonium sulphate is manufactured at Sindri (Jharkhand) by passing synthetic ammonia into a suspension of finely powdered CaSO<sub>4</sub> (Gypsum) in water through which a stream of carbon dioxide is also passed.

$$2NH_3 + H_2O + CO_2 \longrightarrow (NH_4)_2CO_3$$
  
 $CaSO_4 + (NH_4)_2CO_3 \longrightarrow (NH_4)_2SO_4 + CaCO_3$ 

The insoluble CaCO<sub>3</sub> is filtered off. The solution on evaporation under vacuum and cooling yields crystals of ammonium sulphate. Ammonium sulphate is generally called Sindri fertilizer in India.

Ammonium sulphate contains 24–25% ammonia. This ammonia cannot be easily utilised by plants. It is converted into nitrates by nitrifying bacteria in the soil and nitrates are taken up easily by plants from the soil. It should not be frequently used otherwise the soil becomes acidic. It should be generally used after the seeds have germinated.

$$(NH_4)_2SO_4 \xrightarrow[compounds in soil]{Basic} NH_3 \xrightarrow[bacteria]{Nitrifying} Nitrates$$

## (iii) Calcium cyanamide, CaCN<sub>2</sub> (Nitrolim)

It is manufactured by heating calcium carbide with nitrogen at 1100°C in an electric furnace. The product is usually dark grey in colour due to the presence of graphite and is sold in the market in the name of nitrolim.

$$CaC_2 + N_2 \longrightarrow CaCN_2 + C$$
Calcium
cyanamide

In soil, it is converted into urea which then decomposes into ammonia. Ammonia is finally converted into nitrates by nitrifying bacteria

$$CaCN_2 + H_2O + CO_2 \longrightarrow CN \cdot NH_2 + CaCO_3$$

$$CN \cdot NH_2 + H_2O \longrightarrow CO(NH_2)_2$$

$$Urea$$

$$CO(NH_2)_2 + H_2O \longrightarrow 2NH_3 + CO_2$$

It is a slow fertilizer and its effects on fertility are of more permanent nature. It is added to the soil before sowing and not when the plants are actually growing.

## (iv) Calcium ammonium nitrate, Ca(NO<sub>3</sub>)<sub>2</sub>·NH<sub>4</sub>NO<sub>3</sub> (CAN)

It is known as Nangal fertilizer in India. Ammonia is obtained by Haber process. A part of ammonia is converted into nitric acid by Ostwald's process. Excess of nitric acid and ammonia are then made to react with each other to give ammonium nitrate.

$$NH_3 + HNO_3 \longrightarrow NH_4NO_3$$

The solution is concentrated and treated with powdered limestone as to neutralise the free acid present in the solution.

$$2HNO_3 + CaCO_3 \longrightarrow Ca(NO_3)_2 + H_2O + CO_2$$
  
 $Ca(NO_3)_2 + NH_4NO_3 \longrightarrow Ca(NO_3)_2 \cdot NH_4NO_3$   
 $CAN$ 

CAN is hygroscopic. The pellets are, therefore, coated with calcium silicate as to protect from moisture. Ammonium nitrate is explosive but CAN does not explode. This fertilizer is superior to ammonium sulphate as it is more soluble in water and does not make the soil acidic.

## (v) Basic calcium nitrate, Ca(NO<sub>3</sub>)<sub>2</sub>·CaO

It is formed by reacting limestone with nitric acid.

$$CaCO_3 + 2HNO_3 \longrightarrow Ca(NO_3)_2 + H_2O + CO_2$$
  
It is then mixed with lime.  
 $Ca(NO_3)_2 + CaO \longrightarrow Ca(NO_3)_2 \cdot CaO$ 
Basic calcium nitrate

Being highly deliquescent, it is packed in water proof bags. Basic calcium nitrate is also called **Norwegian saltpetre** or **nitrate of lime.** It is preferred to the normal calcium nitrate as a fertilizer since it is less deliquescent.

## (vi) Urea, NH2CONH2

Urea is one of the world's most important chemicals because of its wide use as fertilizer.

It is manufactured by reacting ammonia and carbon dioxide under high atmospheric pressure near 200°C. Ammonium carbamate (NH<sub>2</sub>COONH<sub>4</sub>) formed as an intermediate product changes into urea.

A slurry of water, urea and ammonium nitrate is often applied to crops under the name of "liquid nitrogen". Such a solution can contain upto 30% nitrogen and is easy to store and apply. When applied to the surface of the ground around plants urea is subjected to considerable nitrogen loss. When urea hydrolyses (is decomposed by water) ammonia is formed, out of it some ammonia is lost to the air and some is absorbed by moist soil particles. As much as half of the nitrogen applied can be lost in this way.

Out of the nitrogen fertilizers, urea has the highest nitrogen content equal to 46.6%. It has no explosive property and there is no risk in the storage. It does not alter the pH of the soil. It can be used for all types of crops. However, there is one disadvantage, urea is not so stable as other nitrogenous fertilizers. It decomposes even at lower temperatures in humid atmosphere. It is highly soluble in water and hence requires airtight packing.

Note: Inorganic nitrate fertilizers are water soluble and contribute significantly to nitrate pollution in the ground water of farming regions. Since excess nitrates in drinking water and food supplies cause blood disorders and contribute to the formation of carcinogenic nitrosoamines\*, the present opinion is to keep the nitrate out of the ground water or to remove it in the purification of drinking water.

## Phosphatic Fertilizers

The minerals of phosphorus such as phosphorite,  $[Ca_3(PO_4)_2]$  and apatite,  $[3Ca_3(PO_4)_2 \cdot CaF_2]$  are sparingly

soluble in water and thus do not serve as source of phosphorus for plants. These are, therefore, converted into soluble materials which can act as good fertilizers.

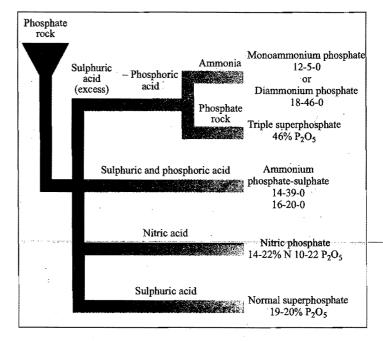

Fig. 10.17 Phosphatic fertilizers from phosphate rock

The important phosphatic fertilizers are:

- (i) Calcium superphosphate
- (ii) Nitrophosphate
- (iii) Triple phosphate
- (iv) Phosphatic slag

## (i) Calcium superphosphate or superphosphate of lime Ca(H<sub>2</sub>PO<sub>4</sub>)<sub>2</sub>·H<sub>2</sub>O + 2(CaSO<sub>4</sub>·2H<sub>2</sub>O)

Calcium phosphate, Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>, is not very useful to a growing plant because of its very low solubility. When calcium phosphate is treated with sulphuric acid it becomes more soluble and is called "superphosphate".

$$\begin{array}{c} Ca_{3}(PO_{4})_{2} + 2H_{2}SO_{4} \longrightarrow \underbrace{Ca(H_{2}PO_{4})_{2} + 2CaSO_{4}}_{Superphosphate} \\ \end{array}$$

It is prepared on a large scale by treating phosphorite or bone ash with calculated quantity of 70% H<sub>2</sub>SO<sub>4</sub>.

$$Ca_{3}(PO_{4})_{2} + 2H_{2}SO_{4} + 5H_{2}O \longrightarrow$$

$$Ca(H_{2}PO_{4})_{2} \cdot H_{2}O + 2CaSO_{4} \cdot 2H_{2}O$$

$$Ca(H_{2}PO_{4})_{2} \cdot H_{2}O + 2CaSO_{4} \cdot 2H_{2}O$$

Superphosphate of lime has 16-20% of P2O5.

<sup>\*</sup>Carcinogens are chemicals, that cause cancer.

## (ii) Nitrophosphate

It is prepared in the same way as superphosphate from phosphorite mineral using nitric acid instead of sulphuric acid.

$$Ca_3(PO_4)_2 + 4HNO_3 \longrightarrow \underbrace{Ca(H_2PO_4)_2 + 2Ca(NO_3)_2}_{Nitrophosphate or}$$

The advantage of this fertilizer is that in addition to phosphorus, it contains nitrogen as well. Thus, this is a mixed fertilizer.

## (iii) Triple superphosphate of lime

This is another form of superphosphate. It is obtained by the action of orthophosphoric acid, H<sub>3</sub>PO<sub>4</sub> (70%) with phosphate mineral.

$$Ca_3(PO_4)_2 + 4H_3PO_4 \longrightarrow 3Ca(H_2PO_4)_2$$

Triple phosphate has calcium hydrogen phosphate but it does not have calcium sulphate that is why percentage of  $P_2O_5$  in triple superphosphate in about three times to calcium superphosphate, and hence called **triple superphosphate**. It has about 42-46% of  $P_2O_5$ .

## (iv) Phosphatic slag or Thomas slag:

It is a by-product of steel industry. When iron ore is burnt with limestone in the presence of air, calcium phosphate and calcium silicate appear as slag.

$$\begin{array}{ccc} 4P + 5O_2 & \longrightarrow & P_4O_{10} \\ 6CaO + P_4O_{10} & \longrightarrow & 2Ca_3(PO_4)_2 \\ CaO + SiO_2 & \longrightarrow & CaSiO_3 \end{array} \right\} Thomas slag$$

The slag being lighter rises on the top of molten metal and is easily separated. It is cooled. The solid mass thus obtained is ground to a fine powder and used as fertilizer. It has 14-18% of  $P_2O_5$ .

#### Potash Fertilizers

Potassium nitrate, potassium chloride and potassium sulphate are used as fertilizers.

#### NPK Fertilizers

Fertilizers containing N, P and K in suitable adjusted proportions are known as NPK fertilizers. These are obtained by mixing nitrogenous, phosphatic and potash fertilizers in suitable proportions. Expression like 4–8–2 used for a mixed fertilizer indicates that it contains 4% N<sub>2</sub>, 8% P<sub>2</sub>O<sub>5</sub> and 2% K<sub>2</sub>O.

In India, plants for the manufacture of fertilizers are established/situated at,

- 1. Sindri (Jharkhand)
- 2. Trombay (Maharashtra)
- 3. Nangl (Punjab)
- 4. Rourkela (Orissa) and
- 5. Namroop (Assam)

# SOME SOLVED PROBLEMS

**Example 1.** Complete and balance the following reactions:

- (i) Copper reacts with HNO<sub>3</sub> to give NO and NO<sub>2</sub> in molar ratio of 2:1. [I.I.T. 1992]
- (ii) Red phosphorus is reacted with iodine in presence of water. [I.I.T. 1992]
- (iii) Ammonium sulphate is heated with a mixture of nitric oxide and nitrogen dioxide.
- (iv) White phosphorus is boiled with a strong solution of sodium hydroxide in an inert atmosphere. [I.I.T. 1993]
- (v) The preparation of ammonium sulphate from gypsum, ammonia and carbon dioxide. [I.I.T. 1990]
- (vi) Nitrogen is obtained by the reaction of ammonia with KMnO<sub>4</sub>. [I.I.T. 1991]
- (vii) Aqueous solution of sodium nitrate is heated with zinc dust and caustic soda. [L.J.T. 1990]
- (viii) Phosphorus reacts with conc. HNO<sub>3</sub> to give phosphoric acid. [I.I.T. 1991]
- (ix) The preparation of phosphine from CaO and white phosphorus. [1.I.T. 1990]
- (x) Sodium nitrite is produced by absorbing oxides of nitrogen in aqueous solution of sodium carbonate. [I.I.T. 1991]

#### **Solution:**

(i) 
$$2HNO_3 \longrightarrow 2NO + H_2O + 3O$$
  
 $3Cu + 3O + 6HNO_3 \longrightarrow 3Cu(NO_3)_2 + 3H_2O$   
 $3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O...(i)$   
 $2HNO_3 \longrightarrow 2NO_2 + H_2O + O$   
 $Cu + O + 2HNO_3 \longrightarrow Cu(NO_3)_2 + H_2O$   
 $Cu + 4HNO_3 \longrightarrow Cu(NO_3)_2 + 2NO_2 + 2H_2O...(ii)$ 

To get NO and  $NO_2$  in the ratio of 2:1, the eqn. (i) be multiplied by two and added in eqn. (ii).

7Cu + 20HNO<sub>3</sub> 
$$\longrightarrow$$
 7Cu(NO<sub>3</sub>)<sub>2</sub> + 4NO + 2NO<sub>2</sub> + 10H<sub>2</sub>O  
(ii) 2P + 3I<sub>2</sub>  $\longrightarrow$  2PI<sub>3</sub>  
2PI<sub>3</sub> + 3H<sub>2</sub>O  $\longrightarrow$  H<sub>3</sub>PO<sub>3</sub> + 3HI  
(iii) NO + NO<sub>2</sub>  $\longrightarrow$  N<sub>2</sub>O<sub>3</sub>  
(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>  $\longrightarrow$  2NH<sub>3</sub> + H<sub>2</sub>SO<sub>4</sub>  
2NH<sub>3</sub> + N<sub>2</sub>O<sub>3</sub>  $\longrightarrow$  2N<sub>2</sub> + 3H<sub>2</sub>O  
(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> + NO + NO<sub>2</sub>  $\longrightarrow$  2N<sub>2</sub> + H<sub>2</sub>SO<sub>4</sub> + 3H<sub>2</sub>O

(iv) 
$$P_4 + 3NaOH + 3H_2O \longrightarrow 3NaH_2PO_2 + PH_3$$
Sodium hypophosphite

(v)  $2NH_3 + H_2O + CO_2 \longrightarrow (NH_4)_2CO_3$ 
 $CaSO_4 + (NH_4)_2CO_3 \longrightarrow (NH_4)_2SO_4 + CaCO_3$ 
(vi)  $2KMnO_4 + H_2O \longrightarrow 2KOH + 2MnO_2 + 3O$ 
 $2NH_3 + 3O \longrightarrow N_2 + 3H_2O$ 

$$2KMnO_4 + 2NH_3 \longrightarrow 2KOH + 2MnO_2 + N_2 + 2H_2O$$
(vii)  $[Zn + 2NaOH \longrightarrow Na_2ZnO_2 + 2H] \times 4$ 
 $NaNO_3 + 8H \longrightarrow NaOH + NH_3 + 2H_2O$ 

$$4Zn + 7NaOH + NaNO_3 \longrightarrow NH_3 + 4Na_2ZnO_2 + 2H_2O$$
(viii)  $[2HNO_3 \longrightarrow H_2O + 2NO_2 + O] \times 10$ 
 $P_4 + 10O + 6H_2O \longrightarrow 4H_3PO_4$ 

$$P_4 + 2OHNO_3 \longrightarrow 4H_3PO_4 + 2ONO_2 + 4H_2O$$
(ix)  $[CaO + H_2O \longrightarrow Ca(OH)_2] \times 3$ 
 $8P + 3Ca(OH)_2 + 6H_2O \longrightarrow 3Ca(H_2PO_2)_2 + 2PH_3$ 
 $8P + 3CaO + 9H_2O \longrightarrow 3Ca(H_2PO_2)_2 + 2PH_3$ 
(x)  $Na_2CO_3 + NO + NO_2 \longrightarrow 2NaNO_2 + CO_2$ 

#### **Example 2.** Answer the following:

- (i) Why concentrated  $H_2SO_4$ , anhydrous  $CaCl_2$  or  $P_4O_{10}$  cannot be used as dehydrating agents for ammonia?
- (ii) Why nitrous oxide supports combustion more vigorously than air?
- (iii) Why red phosphorus is denser and chemically less reactive than white phosphorus?
- (iv) Nitric acid acts as oxidising agent while nitrous acid can act both as an oxidising and a reducing agent.
  - (v) Why commercial nitric acid is generally yellow in colour? **Solution:**
- (i) Conc.  $H_2SO_4$ , anhydrous  $CaCl_2$  and  $P_4O_{10}$  directly react with ammonia.

$$H_2SO_4 + 2NH_3 \longrightarrow (NH_4)_2SO_4$$

$$CaCl_2 + 8NH_3 \longrightarrow CaCl_2 \cdot 8NH_3$$

$$P_4O_{10} + 12NH_3 + 6H_2O \longrightarrow 4(NH_4)_3PO_4$$

(ii) Air has oxygen about 1/5th of the volume while  $N_2O$  on decomposition produces oxygen about 1/3rd of the volume.

Air 
$$\longrightarrow$$
 4 vol.  $N_2 + 1$  vol.  $O_2$ ;  $O_2 = \frac{\text{Total volume}}{5}$   
 $2N_2O \longrightarrow 2N_2 + O_2$ ;  $O_2 = \frac{\text{Total vol. of } N_2 \text{ and } O_2}{3}$ 

- (iii) Red phosphorus is regarded as a polymer consisting of chains of P<sub>4</sub> tetrahedra linked together. This makes red phosphorus denser and less reactive.
- (iv) In HNO<sub>3</sub>, the oxidation state of nitrogen is +5. Nitrogen can only be converted into lower oxidation states as +5 state

is the highest. Thus, it acts only as an oxidising agent. In nitrous acid,  $HNO_2$ , nitrogen is in +3 oxidation state. Thus, it can be lowered or raised. Hence,  $HNO_2$  acts both as an oxidising and a reducing agent.

(v) Nitrogen dioxide is present in HNO<sub>3</sub> which imparts yellow colour to the nitric acid. NO<sub>2</sub> is usually formed by decomposition of HNO<sub>3</sub> in sunlight.

$$4HNO_3 \xrightarrow{Sunlight} 4NO_2 + 2H_2O + O_2$$

**Example 3.** Explain the following with proper reason:

- (i) Nitrogen is a gas while other members of Vth group are solids.
- (ii) A bottle of liquor ammonia should be cooled before opening.
  - (iii) Ammonia has a higher boiling point than phosphine.
    [M.L.N.R. 1993]
  - (iv)  $PF_5$  is known but  $NF_5$  is not. [M.L.N.R. 1992]
- (v) The experimentally determined N—F bond length in  $NF_3$  is greater than the sum of single bond covalent radii of N and F. [LLT. 1995]

#### **Solution:**

- (i) The nitrogen atom is small in size. It can undergo lateral overlapping forming multiple bonds, *i.e.*, nitrogen molecule consists one sigma and two  $\pi$ -bonds (N=N). The discrete molecules are held together by weak van der Waals' forces. Thus, nitrogen is a gas. As the size increases, the lateral overlap is not strong and multiple bonds are not formed. Four atoms link together by single covalent bonds in tetrahedral form. The molecular masses become high and hence the rest of the members of Vth group are solids.
- (ii) Liquor ammonia has high vapour pressure at room temperature. It is cooled before opening as to reduce the vapour pressure inside the bottle in order to prevent bumping.
- (iii) Nitrogen being more electronegative, hydrogen bonding is observed in ammonia, *i.e.*, association of molecules occurs through hydrogen bonding. This property is absent in phosphine.
- (iv) Nitrogen cannot extend its valency from 3 to 5 due to absence of *d*-orbitals while phosphorus shows pentacovalency as *d*-orbitals are present in it.
- (v) The bond length is high due to repulsion of the bonded pair by both nitrogen and fluorine atoms. This is due to their smaller size and high electron density.
- **Example 4.** A colourless inorganic salt (A) decomposes completely at about 250°C to give only two products (B) and (C), leaving no residue. The oxide (C) is a liquid at room temperature and neutral to litmus paper while the gas (B) is a neutral oxide. White phosphorus burns in excess of (B) to produce a strong white dehydrating agent. Write balanced equations for the reactions involved in this process.

[I.I.T. 1996]

#### Solution:

Both (B) and (C) are neutral oxides. (B) helps in the combustion of white phosphorus. Thus, (B) can be nitrous oxide,  $N_2O$ . (A) is liquid at room temperature, thus it can be water,  $H_2O$ .

The inorganic salt (A) is ammonium nitrate,  $NH_4NO_3$  which on decomposition gives  $N_2O$  and  $H_2O$ .

$$\begin{array}{ccc} NH_4NO_3 & \longrightarrow & N_2O + 2H_2O \\ (A) & (B) & (C) \\ \hline \\ 10N_2O + P_4 & \longrightarrow & P_4O_{10} + 10N_2 \\ & & \\ & & \\ Dehydrating \\ & agent \end{array}$$

**Example 5.** -An aqueous solution of a gas (X) shows following reactions:

- (i) It turns red litmus blue.
- (ii) When added in excess to a copper sulphate solution, a deep blue colour is obtained.
- (iii) On addition to ferric chloride solution a brownish precipitate soluble in HNO<sub>3</sub> is obtained.

Identify (X) and give equations for the reactions in step (ii) and (iii). [Roorkee 1991]

#### Solution:

The gas (X) is  $NH_3$ .

Its aqueous solution is  $NH_4OH$  which turns red litmus to blue.

Step (ii)

$$FeCl_3 + 3NH_4OH \longrightarrow Fe(OH)_3 + 3NH_4Cl$$

$$Fe(OH)_3 + 3HNO_3 \longrightarrow Fe(NO_3)_3 + 3H_2O$$

$$Soluble$$

**Example 6.** Give the names and formulae of the compounds described below:

- (a) A chromium compound which on heating gives nitrogen and an oxide of chromium.
- (b) A compound of N, H and O which is used as a freezing salt and decomposes on heating giving a neutral oxide of nitrogen.
- (c) A compound of N, H, C and O which is used as a fertilizer.

#### **Solution:**

(a) Chromium compound is ammonium dichromate,  $(NH_4)_2Cr_2O_7$ .

$$(NH_4)_2Cr_2O_7 \longrightarrow N_2 + Cr_2O_3 + 4H_2O$$

(b) The compound is ammonium nitrate, NH<sub>4</sub>NO<sub>3</sub>.

$$NH_4NO_3 \longrightarrow N_2O + 2H_2O$$
Neutral oxide

(c) The compound is urea, NH<sub>2</sub>CONH<sub>2</sub>.

### **Example 7.** Answer the following:

- (a) Why elemental phosphorus does not exist as  $P_2$  like  $N_2$ ?
- (b) How  $NO_3^-$  and  $PO_3^-$  ions are differ structurally?
- (c) NCl<sub>3</sub> gets readily hydrolysed while NF<sub>3</sub> does not, why?
- (d) Oxides of nitrogen have open chain structures while those of phosphorus have closed chain or cage structures. Why is it so? Illustrate with one structural example for each type of the oxides.

#### Solution:

- (a) Nitrogen because of small size has a tendency to form multiple bonds and thus exist as a diatomic molecule,  $N \equiv N$ . Phosphorus has a comparatively larger size and it has no tendency to form multiple bonds and thus does not form diatomic molecule,  $P \equiv P$ . However, it prefers to form  $P_4$  molecules in which each P is linked to three other P atoms by three single covalent bonds and four P atoms lie at the corners of a regular tetrahedron.
- (b)  $NO_3$  ion exists as a free ion. It has trigonal planar shape as N is in  $sp^2$  hybridized state.

 $PO_3^-$  ion does not exist as free ion but in the polymeric form in which various  $PO_3^-$  units are linked through P-O-P bonds to form either linear or cyclic structures. The P is in  $sp^3$  hybridized state.

- (c) In NCl<sub>3</sub>, Cl has vacant *d*-orbitals to accept lone pair of electrons from oxygen atom of H<sub>2</sub>O molecule. Thus, hydrolysis is possible. In NF<sub>3</sub>, no *d*-orbitals are present.
- (d) Nitrogen on account of small size and high electronegativity has a strong tendency to form multiple bonds ( $p\pi p\pi$  bonds) with oxygen and form oxides with open chain structures. Phosphorus has no tendency to form  $p\pi p\pi$  bonds with oxygen due to its large size and prefers to form single bonds. As a result, closed chain or cage structure results.

**Example 8.** (a)  $NF_3$  does not have donor properties like ammonia. Explain.

- (b) PCl<sub>5</sub> acts as a chlorinating agent in organic reactions. Give reason.
- (c)  $PCl_5$  exists as  $[PCl_4]^+$   $[PCl_6]^-$  but  $PBr_5$  exists as  $[PBr_4]^+Br^-$ . Explain.

#### **Solution:**

(a) NF<sub>3</sub> has a pyramidal shape like NH<sub>3</sub> with one lone pair of electrons on N-atom.

The lone pair on N is in opposite direction to the N—F bond moments and therefore, it has a very little dipole moment. Thus, lone pair is not very effective and does not show donor properties. However, NH<sub>3</sub> has high dipole moment because its lone pair is in the same direction as the N—H bond moments. Electron density is high and thus, donor properties are observed.

- (b) The structure of PCl<sub>5</sub> is trigonal bipyramid. The axial P—Cl bonds are slightly larger than the equatorial P—Cl bonds. The molecule is, thus, less stable. It breaks upto lose two chlorine atoms present on axial positions and, thus, acts as a chlorinating agent.
- (c) The formation of both PCl<sub>5</sub> and PBr<sub>5</sub> is due to  $sp^3d$ -hybridization of phosphorus, *i.e.*, both have a trigonal bipyramidal geometry which is not a regular structure and, thus, is not very stable. To attain more stable structure, PCl<sub>5</sub> splits up into tetrahedral and octahedral structures.

$$2PCl_5 \Longrightarrow [PCl_4]^+ [PCl_6]^-$$
Tetrahedral Octahedral

But  $PBr_5$  does not split up in the same fashion. The anion  $[PBr_6]^-$  is not possible due to large size of Br atoms.  $PBr_5$ , therefore, splits up into stable tetrahedral structure as,

$$PBr_5 \Longrightarrow [PBr_4]^+Br^-$$
Tetrahedral

**Example 9.** (a) Can  $PCl_5$  act as an oxidising as well as a reducing agent? Justify.

- (b) Give the disproportionation reaction of  $H_3PO_3$ .
- (c) The HNH angle value is higher than HPH, HAsH and HSbH angles. Why?
- (d) Why  $NH_3$  is basic while  $BiH_3$  is only feebly basic? Explain.

#### Solution:

(a) Phosphorus can exhibit a maximum oxidation state of +5. In PCl<sub>5</sub>, the oxidation state of phosphorus is +5. Thus, it cannot increase its oxidation state beyond +5 and consequently it is unable to act as a reducing agent. However, it can act as an oxidising agent by undergoing decrease in oxidation state. For example,

$$PCl_5 + H_2 \longrightarrow PCl_3 + 2HCl$$
 $+5 + 3$ 
 $PCl_5 + Sn \longrightarrow 2PCl_3 + SnCl_4$ 

(b)  $H_3PO_3$  on heating is converted into  $H_3PO_4$  (oxidation state +5) and  $PH_3$  (oxidation state -3). Thus, this is a disproportionation reaction.

- (c) In all the hydrides of group 15 elements, the central atom undergoes  $sp^3$ -hybridisation. The three hybrid orbitals form sigma bonds with three hydrogen atoms and the fourth contains a lone pair of electrons. The lone pair-bond pair repulsions are larger than bond pair-bond pair repulsion. In ammonia both forces are equally present in opposite directions, hence the bond angle decreases from 109°28′ to 107°5′. However, as we go from N to Sb, the size increases and the repulsions between bond pair—bond pair go on decreasing and thus the bond angles keep on decreasing from NH<sub>3</sub> to SbH<sub>3</sub>.
- (d) The central atoms in both NH<sub>3</sub> and BiH<sub>3</sub> contain a lone pair of electrons and thus, both should behave as Lewis bases. But the size of Bi atom is much larger than the nitrogen atom. The electron density on nitrogen atom is much higher in comparison to Bi atom. Consequently, the tendency to donate the electron pair by N in NH<sub>3</sub> is much higher than the tendency of Bi in BiH<sub>3</sub>. Therefore, NH<sub>3</sub> is basic while BiH<sub>3</sub> is feebly basic.

**Example 10.** Illustrate, how does copper metal give different products on reaction with HNO<sub>3</sub>.

#### **Solution:**

Nitric acid acts as an oxidising agent as well as an acid when it reacts with copper. Dilute HNO<sub>3</sub> evolves nitric oxide while concentrated HNO<sub>3</sub> gives nitrogen dioxide.

$$2HNO_{3} \text{ (Dilute)} \longrightarrow H_{2}O + 2NO + 3[O]$$

$$[Cu + O \longrightarrow CuO] \times 3$$

$$[CuO + 2HNO_{3} \longrightarrow Cu(NO_{3})_{2} + H_{2}O] \times 3$$

$$3Cu + 8HNO_{3} \text{ (Dilute)} \longrightarrow 3Cu(NO_{3})_{2} + 2NO + 4H_{2}O$$

$$2HNO_{3} \text{ (Conc.)} \longrightarrow H_{2}O + 2NO_{2} + [O]$$

$$Cu + O \longrightarrow CuO$$

$$CuO + 2HNO_{3} \longrightarrow Cu(NO_{3})_{2} + H_{2}O$$

$$Cu + 4HNO_{3} \longrightarrow Cu(NO_{3})_{2} + 2NO_{2} + 2H_{2}O$$

# **SUMMARY AND IMPORTANT POINTS TO REMEMBER**

- 1. VA or 15th group of the periodic table consists of six elements—nitrogen, phosphorus, arsenic, antimony, bismuth and ununpentium. These elements are collectively known as **pnictogens** and their compounds **pnictides**.
- 2. These are p-block elements as the last differentiating electron is accommodated on np shell. They have general configuration of  $ns^2np^3$  configuration. All the p-orbitals of the outer shell are singly occupied.

$$\begin{array}{ccc}
ns & np \\
\downarrow\uparrow & \uparrow & \uparrow & \uparrow
\end{array}$$

These elements are not so reactive as half filled orbitals are present which are fairly stable. Nitrogen behaves as a noble element under ordinary conditions.

3. VA group is a mixed group of metals, metalloids and non-metals. Metallic nature increases as the atomic number increases.

Nitrogen and phosphorus combine with electropositive elements and form nitrides and phosphides. Bismuth and antimony form alloys.

- 4. Nitrogen is a gas, the phosphorus is a waxy solid and can pass into vapour state readily. The remaining elements are solids and possess metallic lustre.
  - Nitrogen is a diatomic molecule,  $N \equiv N$ . The molecule has one sigma and two  $\pi$ -bonds. The dissociation energy is very large (225 kcal mol<sup>-1</sup>) and thus, is a stable and inert under ordinary conditions.
  - P, As and Sb all exist as discrete tetratomic tetrahedral molecules, viz., P<sub>4</sub>, As<sub>4</sub> and Sb<sub>4</sub> as these are not capable of forming multiple bonds. The angle between X—X—X is 60°.
- 5. In VA or 15th group:
  - (a) density of the elements increases down the group.
  - (b) melting points increase from nitrogen to As and then decreases from As to Bi.
    - The lower values are due to formation of three covalent bonds instead of five covalent bonds due to inert pair effect.
  - (c) atomic radii increase down the group.
  - (d) ionisation energy decreases regularly on moving down the group.
    - The ionisation energy of N is very high due to small size.
  - (e) electronegativity decreases gradually on moving down the group.
  - (f) all the elements except bismuth show allotropy.
  - (g) N, P and As exhibit the property of catenation but this property is much less than IVA elements.
- 6. All the members can show +5 oxidation state toward oxygen. Nitrogen and phosphorus generally exhibit -3 oxidation state due to high electronegativity. +3 oxidation state is observed when only p electrons are used. Its stability increases due to inert pair effect.
  - Nitrogen besides -3, +3 and +5 oxidation states, exhibits a large number of oxidation states from -3 to +5. -3 in NH<sub>3</sub>, -2 in NH<sub>2</sub>·NH<sub>2</sub>, -1 in NH<sub>2</sub>OH, 0 in N<sub>2</sub>, +1 in N<sub>2</sub>O, +2 in NO, +3 in N<sub>2</sub>O<sub>3</sub>, +4 in N<sub>2</sub>O<sub>4</sub> or NO<sub>2</sub> and +5 in N<sub>2</sub>O<sub>5</sub> and HNO<sub>3</sub>.
- 7. These elements attain stable configuration by forming three covalent bonds. Except nitrogen, all other elements have *d*-orbitals in the valence shell. As a result, one of the two *ns*-electrons may be promoted to *nd*-orbitals to have five unpaired orbitals in the valence shell. These can be utilised to form five bonds. However, nitrogen can show a maximum covalency of 4 when it donates the *ns*-electron pair to Lewis acids.
  - Sb and Bi can lose three electrons to form  $M^{3+}$  ions. Both SbF<sub>3</sub> and BiF<sub>3</sub> are ionic solids.  $M^{3+}$  ions are not stable in solution. They are rapidly hydrolysed as SbO<sup>+</sup> and BiO<sup>+</sup> ions. However,  $M^{3+}$  ions are stable in strong acids.
- **8.** Nitrogen is found in free as well as combined state. It forms 75% by mass and 78% by vol. of atmosphere. In combined state, it occurs as nitrates, proteins and amino acids. Phos-

- phorus is eleventh most abundant element in combined state. It is never found free in nature. P is essential for life of both animals and plants. It is present in DNA, RNA, ADP, ATP, etc. As, Sb and Bi are not abundant.
- 9. Nitrogen is chemically inert under ordinary conditions as it has very high dissociation energy. At high temperatures, it can react with other elements. Phosphorus (white form) is extremely reactive. The strained structure of P<sub>4</sub> is responsible for this. The heavier elements are less reactive.
  - Only nitrogen in this group is capable of forming  $p\pi$ - $p\pi$  multiple bonds within itself and with carbon, oxygen, etc., on account of small size. Phosphorus and other members do not form  $p\pi$ - $p\pi$  multiple bonds but they show multiple bonding of  $d\pi$ - $p\pi$ .
- 10. (a) Oxides of type  $X_2O_3$ ,  $X_2O_4$  and  $X_2O_5$  are formed by the elements of group 15.
  - (b) Greater is the electronegativity more is the acidic nature of its oxides.
  - (c) Acidic nature of each type decreases from N to Bi.

(However, it shows feeble acidic character with strong alkali.)

Acidic nature of  $M_2O_4$  oxides also decreases from  $N_2O_4$  to  $Bi_2O_4$ .

- (d) Thermal stability decreases in each series from N to Bi.
- (e) In the oxides of a particular element, the acidic nature increases as the percentage of oxygen increases or the oxidation state increases.
- 11. (a) All the members of group 15 form oxyacids or oxoacids.
  - (b) The oxyacids of nitrogen are: hyponitrous acid (H<sub>2</sub>N<sub>2</sub>O<sub>2</sub>), nitroxylic acid (H<sub>2</sub>N<sub>2</sub>O<sub>4</sub>), nitrous acid (HNO<sub>2</sub>), nitric acid (HNO<sub>3</sub>), peroxynitric acid (HNO<sub>4</sub>).
    - Nitrous acid is unstable, weak monobasic acid, forms stable salts. This acts as an oxidising and a reducing agent. Nitric acid is a stable, strong monobasic acid. It is a strong oxidising agent.
    - (c) Phosphorus forms two types of oxyacids, one having P in +1 or +3 oxidation state, *i.e.*, phosphorus acids and other having P in +4 or +5 oxidation state, *i.e.*, phosphoric acids. Phosphorus acids act as reducing agents as they tend to disproportionate. The important oxyacids of phosphorus are: hypophosphorus acid (H<sub>3</sub>PO<sub>2</sub>), phosphorus acid (H<sub>3</sub>PO<sub>3</sub>), orthophosphoric acid (H<sub>3</sub>PO<sub>4</sub>), metaphosphoric acid (HPO<sub>3</sub>), hypophosphoric acid (H<sub>4</sub>P<sub>2</sub>O<sub>6</sub>) and pyrophosphoric acid (H<sub>4</sub>P<sub>2</sub>O<sub>7</sub>). The number of OH group or groups in oxoacids of phosphorus decides the basicity of the acid.

Acid  $H_3PO_2$   $H_3PO_3$   $H_3PO_4$   $HPO_3$   $H_4P_2O_6$   $H_4P_2O_7$  Basicity 1 2 3 1 4 4 Each oxoacid of phosphorus contains at least one P=O unit and one P—OH unit.

- (d) Arsenic forms two oxyacids—arsenious acid (H<sub>3</sub>AsO<sub>3</sub>) and arsenic acid (H<sub>3</sub>AsO<sub>4</sub>). Antimony forms only one acid H<sub>3</sub>SbO<sub>3</sub>. Bismuth also forms one stable oxoacid, HBiO<sub>3</sub> meta-bismuthic acid.
- (e) The strength and stability of oxoacids having the element in same oxidation state decreases down the group.
- 12. All the members of this group form hydrides of the type  $MH_3$ .
  - (a) All the hydrides are colourless gases.
  - (b) Their smell becomes more and more disagreeable from N to Bi.
  - (c) The poisonous nature increases from NH<sub>3</sub> to BiH<sub>3</sub>.
  - (d) NH<sub>3</sub> is highly soluble in water but other hydrides are less soluble.
  - (e) The basic character decreases from NH<sub>3</sub> to BiH<sub>3</sub>.
  - (f) Thermal stability decreases from NH<sub>3</sub> to BiH<sub>3</sub>. BiH<sub>3</sub> decomposes at room temperature.
  - (g) The reducing nature increases. This shows *M*—H bond strength decreases from NH<sub>3</sub> to BiH<sub>3</sub>.
  - (h) The shape of these hydrides is pyramidal. The formation is due to  $sp^3$  hybridization. The bond angle is never equal to ideal angle 109°28′. The actual angle in NH<sub>3</sub> is 106°5′.
  - Hydrogen bonding is present in NH<sub>3</sub>. No hydrogen bonding is present in other hydrides.
- 13. Except nitrogen, the rest of the elements of group 15 form two series of halides  $MCl_3$  and  $MCl_5$ . However, all form trihalides but one or more pentahalides are formed. Nitrogen does not form pentahalides due to absence of d-orbitals.
  - (a) All the trihalides are stable except NCl<sub>3</sub>, NBr<sub>3</sub> and NI<sub>3</sub>. The unstable nature is due to low polarity of N—X and a large difference in the size of N and Cl.
  - (b) The trihalides have distorted tetrahedral structure involving  $sp^3$  hybridization.
  - (c) The trihalides act as Lewis bases. This tendency decreases from N to Bi.
  - (d) Except NF<sub>3</sub> and PF<sub>3</sub>, all the trihalides are hydrolysed by water.
  - (e) Except N and Bi, other members form pentahalides especially fluorides.
  - (f) Pentahalides have a trigonal bipyramid shape  $(sp_s^3d)$  hybridization).
  - (g) Pentahalides decompose on heating into lower halides.
  - (h) Pentahalides are hydrolysed by water.
  - (i) X-ray studies have shown that solid PCl<sub>5</sub> is an ionic compound composed of [PCl<sub>4</sub>]<sup>+</sup>[PCl<sub>6</sub>]<sup>-</sup>. Solid PBr<sub>5</sub> exists as [PBr<sub>4</sub>]<sup>+</sup> Br<sup>-</sup>.
- 14. With the exception of nitrogen, all other elements of group 15 form sulphides. The sulphides of arsenic and antimony are soluble in yellow ammonium sulphide or ammonium sulphide and form thio-compounds.
- **15.** Nitrogen differs from the rest of the family members on account of following factors:
  - (a) small size of nitrogen atom.
  - (b) high value of electronegativity.
  - (c) absence of d-orbitals in the valency shell.
  - (d) tendency to form multiple bonds.

- 16. Scheele showed that air is a mixture of two gases: fire air (oxygen) and foul air (nitrogen). D.Rutherford named foul air as mephitic air (killer of life). Later on the element was found to be present in nitre and thus, the name nitrogen was proposed.
- 17. Nitrogen can be obtained either from air or from the nitrogen compounds. In the laboratory, it is obtained by heating a mixture of ammonium chloride and sodium nitrite (NH<sub>4</sub>NO<sub>2</sub>) or ammonium dichromate. Pure nitrogen is obtained by passing ammonia vapours on heated CuO. It is also formed by action of nitrous acid on urea.
- 18. Nitrogen is a colourless, odourless and tasteless gas. It is not poisonous but animals do not survive in its atmosphere due to absence of oxygen. It is non-combustible and does not help in combustion. It combines with oxygen, hydrogen, boron, silicon and certain metals under specific conditions. It combines with CaC<sub>2</sub> to form nitrolim (CaCN<sub>2</sub>+C) at 1000°C, which is used as a fertilizer.
- 19. Nitrogen forms three hydrides: (i) ammonia (NH<sub>3</sub>) (ii) hydrazine (NH<sub>2</sub>·NH<sub>2</sub>) and (iii) hydrazoic acid (N<sub>3</sub>H). Ammonia is obtained on a small scale by the action of caustic soda or lime on ammonium compounds, by reacting nitrides with water, by doing reduction of nitrates and nitrites with zinc and caustic soda, by heating ammonium compounds and by action of NaOH on urea.
- **20.** For drying of NH<sub>3</sub>, quicklime (CaO) is used. Other dehydrating agents like H<sub>2</sub>SO<sub>4</sub>, CaCl<sub>2</sub> and P<sub>2</sub>O<sub>5</sub> cannot be used as they react with NH<sub>3</sub>.
- 21. On large scale, ammonia is manufactured:(i) by Haber process (ii) by Bosch's process (iii) by cyanamide process or as a by-product during coal distillation.
- 22. NH<sub>3</sub> is lighter than air and is highly soluble in water due to hydrogen bonding. It can be easily liquefied at room temperature by application of pressure. Liquid NH<sub>3</sub> has a large heat of vaporisation. It is, therefore, used in ice plants. Ammonia is a Lewis base as it donates an electron pair. It forms ammonium salts with acids. It is oxidised to nitrogen. When chlorine in excess, an explosive substance NCl<sub>3</sub> is formed. Iodine flakes when rubbed with liquor ammonia form a dark brown precipitate of ammoniated nitrogen iodide (NH<sub>3</sub>NI<sub>3</sub>) which explodes readily on drying.
  - Aqueous ammonia (NH<sub>4</sub>OH) form many metal hydroxides. Some of them remain in solution in the form of complex compounds.
- 23. Alkaline solution of K<sub>2</sub>HgI<sub>4</sub> (Nessler's reagent) gives brown precipitate with NH<sub>3</sub> called iodide of Millon's base (H<sub>2</sub>NHgOHgI).
- 24. Ammonia is used for the manufacture of nitric acid, sodium bicarbonate and ammonium compounds. Ammonium sulphate, ammonium calcium nitrate, etc., are used as fertilizers. Ammonium nitrate is used in certain explosives. Ammonium hydroxide is used in laboratory. It is also used for the manufacture of urea and for making artificial silk. Liquid NH<sub>3</sub> is used in refrigeration.
- 25. Nitrogen forms five oxides: (i) N<sub>2</sub>O, nitrous oxide (laughing gas) (ii) NO, nitric oxide (iii) N<sub>2</sub>O<sub>3</sub>, nitrogen trioxide (iv) NO<sub>2</sub> or N<sub>2</sub>O<sub>4</sub>, nitrogen dioxide (v) N<sub>2</sub>O<sub>5</sub>, nitrogen pentoxide.

- (a) Except  $N_2O_5$ , all oxides of nitrogen are gases at room temperature.
- (b) N<sub>2</sub>O and NO are neutral oxides while N<sub>2</sub>O<sub>3</sub>, NO<sub>2</sub> and N<sub>2</sub>O<sub>5</sub> are acidic oxides. The acidic nature increases as percentage of oxygen increases.
- (c) N<sub>2</sub>O is a colourless gas with pleasant odour and sweet taste. When inhaled in moderate quantity, it produces hysterical laughter, hence named as laughing gas. N<sub>2</sub>O is a linear and unsymmetrical molecule.

$$[: \stackrel{\stackrel{-}{N}}{=} \stackrel{+}{N} = \stackrel{\stackrel{-}{O}}{:} \longleftrightarrow : \stackrel{+}{N} = \stackrel{\stackrel{-}{N}}{\longrightarrow} \stackrel{\stackrel{-}{O}}{:}]$$

It is used as anaesthetic in dental or other minor surgical operations in form of a mixture of  $N_2O$  and  $O_2$ .

- (d) NO is a colourless gas, slightly heavier than air. It is paramagnetic indicating the presence of unpaired electron in the molecule (:N •••• O:).
  - In the liquid and solid states, it forms a loose dimer,  $N_2O_2$ .
- (e) N<sub>2</sub>O<sub>3</sub> condenses to a blue coloured liquid at -30°C. The liquid when warmed decomposes into NO and NO<sub>2</sub>. It is called nitrous anhydride as forms nitrous acid with water. It is represented as O=N-O-N=O.
- (f) NO<sub>2</sub> is a brown coloured gas with pungent odour. The liquid and solid is entirely N<sub>2</sub>O<sub>4</sub> (dimer) at low temperature. The molecule is V-shaped with O—N—O bond angle 132° and N—O bond length 1.19 Å. The molecule is an odd electron molecule.
- (g) N<sub>2</sub>O<sub>5</sub> is a white crystalline solid. It is formed by action of P<sub>2</sub>O<sub>5</sub> with conc. HNO<sub>3</sub>. It reacts with water and forms nitric acid. It is, thus, known as nitric anhydride. It exists as a symmetrical molecule in gaseous state, O<sub>2</sub>NONO<sub>2</sub>. X-rays studies reveal that solid N<sub>2</sub>O<sub>5</sub> is ionic in nature, i.e., nitronium nitrate NO<sub>2</sub><sup>+</sup>NO<sub>3</sub><sup>-</sup>.
- 26. Nitrous acid is unknown in free state but known only in solutions. It forms two series of organic derivatives, the nitrites (R—ONO) and nitro compounds (R—NO<sub>2</sub>). It is, thus, considered to be tautomeric mixture of two forms (HON=O and H—N—O).
- 27. HNO<sub>3</sub>, nitric acid was earlier called as *aqua fortis* (meaning strong water). It is a monobasic acid. It reacts with basic oxides, carbonates, bicarbonates and hydroxides forming corresponding salts. It usually acquires yellow colour, due to its decomposition by sunlight into NO<sub>2</sub>. The yellow colour can be removed by warming it to 60–80°C and bubbling dry air through it. It has extremely corrosive action on skin and causes painful sores.

It acts as a strong oxidising agent. Non-metals are converted into highest oxyacids by hot and conc. HNO<sub>3</sub>. NO<sub>2</sub> gas is evolved (S to H<sub>2</sub>SO<sub>4</sub>; P to H<sub>3</sub>PO<sub>4</sub>, C to H<sub>2</sub>CO<sub>3</sub>; I<sub>2</sub> to HIO<sub>3</sub>; As to H<sub>3</sub>AsO<sub>4</sub>; Sb to H<sub>3</sub>SbO<sub>4</sub> and Sn to H<sub>2</sub>SnO<sub>3</sub>). Most of the metals except noble metals are attacked by HNO<sub>3</sub>. It plays double role in action on metals, *i.e.*, it acts as an acid as well as an oxidising agent. Before the hydrogen is allowed to escape, nitric acid is reduced into number of products such

as NO<sub>2</sub>, NO, N<sub>2</sub>O, N<sub>2</sub> or NH<sub>3</sub>. It also oxidises a number of compounds.

Concentration of nitric acid	Metal	Main products
Very Dilute HNO <sub>3</sub>	Mg, Mn	H <sub>2</sub> + metal nitrate
very Email Title3	Fe, Zn, Sn	NH <sub>4</sub> NO <sub>3</sub> + metal nitrate
	Pb, Cu, Ag, Hg	NO + metal nitrate
Dilute HNO <sub>3</sub>	Fe, Zn	N <sub>2</sub> O + metal nitrate
	Zn, Fe, Pb, Cu, Ag	NO <sub>2</sub> + metal nitrate
Conc. HNO <sub>3</sub>	-Sn	NO <sub>2</sub> + H <sub>2</sub> SnO <sub>3</sub> Metastannic acid
Conc. HNO <sub>3</sub>	Fe, Co, Ni, Cr, Al	rendered passive

- **28.** Noble metals like gold, platinum, iridium, rhodium, etc., dissolve in aqua-regia (3 parts conc. HCl plus one part conc. HNO<sub>3</sub>). Aqua-regia forms nascent chlorine which attacks noble metals.
- **29.** The replacement of one or more hydrogen atoms of an organic compound by a nitro group (—NO<sub>2</sub>) is known as nitration. The nitration occurs in presence of conc. H<sub>2</sub>SO<sub>4</sub> with the formation of nitronium ion, NO<sub>2</sub><sup>+</sup>.

$$HNO_3 + 2H_2SO_4 \Longrightarrow NO_2^+ + 2HSO_4^- + H_3O_4^+$$

Proteins are attacked by HNO<sub>3</sub> forming a yellow nitro compound called **xanthoprotein**.

A number of organic compounds are oxidised. Sawdust catches fire when HNO<sub>3</sub> is poured over it. Turpentine oil bursts into flame when treated with fuming HNO<sub>3</sub>. Cane sugar is oxidised to oxalic acid.

- **30.** HNO<sub>3</sub> is used in the manufacture of explosives like T.N.T., picric acid, nitroglycerine, etc. It is also used in the manufacture of fertilizers, artificial silk, dyes, drugs, perfumes, sulphuric acid, nitrates, etc. It is a laboratory reagent used as a solvent for metals.
- **31.** The name phosphorus has been derived from the property of glowing in the dark.

(Greek word, phos = light and phero = I carry.)

Phosphorus is extracted either from phosphorite or bone ash by the application of either retort process (old process) or electrothermal process (modern process). In the modern process, phosphorite is mixed with carbon and silica. The mixture is introduced into the electric furnace and heated at 1400–1600°C. Vapours of phosphorus are condensed under water. It is further purified by melting under acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and is redistilled.

- **32.** Phosphorus exists in a number of allotropic forms. These are:
  - (a) yellow or white phosphorus
  - (b) red phosphorus
  - (c) scarlet phosphorus
  - (d) black phosphorus

The main allotropic forms are yellow and red.

The yellow form is the common variety. This form is chemically active. It is a transparent waxy solid and can be easily cut with knife. It has garlic odour and is poisonous in nature. Vapours are also injurious. Persons working with phosphorus develop a disease known as phossy jaw.

This form undergoes slow combustion in contact with air and glows in dark. This property is called chemiluminescence. It readily catches fire giving dense fumes of P<sub>2</sub>O<sub>5</sub> and therefore, kept in water.

When heated in inert atmosphere at 240°C, it changes into red variety. It is odourless and non-poisonous in nature. It does not show phosphorescence. It is not active in nature. It is regarded as a polymer consisting of P<sub>4</sub> tetrahedral chains.

- 33. Yellow phosphorus is used as a rat poison. Red phosphorus is used in match industry and for making of HBr and HI. Radioactive phosphorus (P<sup>32</sup>) is used in the treatment of leukemia and other blood disorders. It is used for making incendiary bombs and smoke screens.
- 34. Phosphine is prepared by boiling yellow phosphorus with a concentrated solution of sodium hydroxide in inert atmosphere. Besides PH<sub>3</sub>, small amounts of H<sub>2</sub> and P<sub>2</sub>H<sub>4</sub> are also formed. As soon as the bubbles of the gas come in contact with air, they catch fire forming rings of smoke known as vortex rings. This combustion is due to presence of P<sub>2</sub>H<sub>4</sub>. Pure phosphine can be obtained by using alcoholic potassium hydroxide in place of aqueous NaOH. It is a colourless gas, heavier than air, garlic like odour and poisonous in nature. Pure PH3 does not spontaneously inflame. It burns in air or oxygen at 150°C. The spontaneous inflammability at the time of preparation (due to presence of P<sub>2</sub>H<sub>4</sub>) is used in making Holme's signals. The phosphine is less basic and more reducing than NH<sub>3</sub>. The bond angle H—P—H is 93°.
- 35. Phosphorus forms three important oxides. These exist in dimeric forms.
  - (i) Phosphorus trioxide (P<sub>4</sub>O<sub>6</sub>)
  - (ii) Phosphorus tetroxide (P<sub>4</sub>O<sub>8</sub>)
  - (iii) Phosphorus pentoxide (P<sub>4</sub>O<sub>10</sub>)

In the molecule of P<sub>4</sub>O<sub>6</sub>, the phosphorus atoms lie at the tetrahedral position with each other and the 6 oxygen atoms are inserted between them. Each P is bonded covalently to three O-atoms and each oxygen atom is bonded to two phosphorus atoms.

The structures of P<sub>4</sub>O<sub>8</sub> and P<sub>4</sub>O<sub>10</sub> are similar to P<sub>4</sub>O<sub>6</sub> with a difference that in P<sub>4</sub>O<sub>8</sub> two alternate P-atoms are also linked with an additional oxygen atom each and in P<sub>4</sub>O<sub>10</sub> each phosphorus atom is linked with an additional oxygen atom by a coordinate linkage.

Structure of P<sub>4</sub>O<sub>6</sub>

P<sub>4</sub>O<sub>10</sub> is most effective drying or dehydrating agent.

**36.** Following are some important compounds:

(i) Scheele's green

CuHAsO<sub>3</sub>

(ii) Graham salt

 $(NaPO_3)_6$ 

(iii) Paris green

(CH3COO)2Cu-3Cu(AsO2)2

(iv) Pearl white

**BiOCl** 

(v) Nitrophosphate

 $Ca(H_2PO_2)_2 + 2Ca(NO_3)_2$ 

(vi) Superphosphate of lime Ca(H<sub>2</sub>PO<sub>4</sub>)<sub>2</sub>H<sub>2</sub>O + 2CaSO<sub>4</sub>·2H<sub>2</sub>O

(vii) Thomas slag

2Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>·CaSiO<sub>3</sub>

(viii) Sindri fertilizer

(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>

(ix) Nangal fertilizer (CAN) Ca(NO<sub>3</sub>)<sub>2</sub>·NH<sub>4</sub>NO<sub>3</sub>

(x) Amatol

80% NH<sub>4</sub>NO<sub>3</sub> + 20% T.N.T.

(xi) Ammonal

NH<sub>4</sub>NO<sub>3</sub> + Al powder

(small quantity)

(xii) Swarts reagent

SbF<sub>3</sub>

(xiii) Tartaremetic (Potassium antimonyl tartarate)

- (xiv) Angeli's salt Na<sub>2</sub>N<sub>2</sub>O<sub>3</sub>·H<sub>2</sub>O 37. Arsenic trioxide is called white arsenic and is a poison. Traces
- of arsenic are detected by Marsh test. 38. Hydrazine is called diacid base and can form salts with one or two equivalents of an acid. Hydrazine (NH<sub>2</sub>·NH<sub>2</sub>) and its derivatives are used as rocket-fuels.

Hydrazoic acid (N<sub>3</sub>H) is a fairly strong acid, stronger than acetic acid but weaker than mineral acids. N<sub>3</sub>, azide is a pseudohalogen ion. Hydrazoic acid acts both as oxidising and a reducing agent.

- 39. Both NF<sub>3</sub> and NH<sub>3</sub> have pyramidal structures with bond angles 102° and 107° respectively. Their dipole moments are different-NF<sub>3</sub> (0.24 D) and NH<sub>3</sub> (1.48 D). The difference is due to the fact that while the dipole moment due to N-F bonds in NF<sub>3</sub> are in opposite direction to the direction of dipole moment of the lone pair on N-atom which partly cancel out, the dipole moments of N—H bonds in NH3 are in the same direction of the dipole moment of the lone pair on N which add up.
- 40. In case of phosphorus trihalides,  $PX_3$  (X = F, Cl, Br, I) the bond angle increases from PF<sub>3</sub> to PI<sub>3</sub>.
- 41. Hydroxylamine, NH2OH, is a hydroxy hydride of nitrogen. It is a derivative of ammonia. It is a weaker base than NH<sub>3</sub>. It behaves as a mild reducing agent as well as an oxidising
- 42. Some ammonium compounds decompose without evolving NH<sub>3</sub>.

$$\begin{array}{c} NH_4NO_2 \longrightarrow N_2 + 2H_2O \\ NH_4NO_3 \longrightarrow N_2O + 2H_2O \\ (NH_4)_2Cr_2O_7 \longrightarrow N_2 + Cr_2O_3 + 4H_2O \end{array}$$

# -••• PRACTICE PROBLEMS -•••-

## ■ Subjective Type Questions

#### 1. Answer the following:

- (i) Why nitrogen is less reactive at room temperature?
- (ii) NF<sub>5</sub> is not known. Why?
- (iii) Why BiH<sub>3</sub> is strongest reducing agent?
- (iv) Which oxide of nitrogen becomes brown when released in air?
- (v) Name two neutral oxides of nitrogen.

#### 2. Answer the following:

- (i) Why does PCl<sub>3</sub> fume in air?
- (ii) Which element of group 15 is found in abundance in nature?
- (iii) In which is the bond angle higher, PH<sub>4</sub><sup>+</sup> ion or PH<sub>3</sub> molecule?
- (iv) Are all the five bonds in PCl<sub>5</sub> molecule equivalent?
- (v) Name three allotropic forms of phosphorus. Which is most reactive?
- (vi) What does the word cryogen mean?

#### 3. Give reason:

- (a) Why is ammonia highly soluble in water?
- (b) Nitrogen dioxide is paramagnetic in gaseous state.
- (c) Why does NH<sub>3</sub> act as a Lewis base?
- (d) Why conc. H<sub>2</sub>SO<sub>4</sub> cannot be used as dehydrating agent for NH<sub>3</sub>?
- (e) Ammonia has higher boiling point than phosphine.

#### 4. Explain briefly, why:

- (a) White phosphorus is more reactive than red phosphorus?
- (b) Hydrazine is unstable?
- (c) Trihalides of nitrogen cannot be oxidised to pentahalides?
- (d) NO is paramagnetic whereas NO<sup>+</sup> is diamagnetic?
- (e) Does H<sub>3</sub>PO<sub>3</sub> act as a reducing agent but H<sub>3</sub>PO<sub>4</sub> does not?
- **5.** Give the names and formulae of the compounds described below:
  - (i) A compound of N, H and O which on heating gives laughing gas.
  - (ii) A compound of N, H and O which on heating gives nitrogen gas.
  - (iii) A compound of Ca, P and O which is found in bones.
  - (iv) A compound of N and H which is used as refrigerant.
  - (v) A compound of N and H which behaves like an acid.
  - (vi) A compound of N and H which is used as a rocket fuel.
  - (vii) A compound of N, H, S and O which is used as a fertilizer.
  - (viii) A compound of N, H and O which is used for making oximes.
  - (ix) Two neutral oxides of nitrogen.
  - (x) The oxyacid of phosphorus is used for the preparation of HBr and HI from bromides and iodides respectively.
- 6. Describe the action of heat on the following compounds:
  - (i) Ammonium nitrate
  - (ii) Ammonium nitrite
  - (iii) Ammonium chloride

- (iv) A mixture of NaNO2 and NH4Cl
- (v) Ammonium dichromate
- (vi) Orthophosphoric acid
- (vii) Phosphorus acid
- (viii) Hypophosphorus acid
- (ix) Copper nitrate
- (x) Silver nitrate
- 7. Complete and balance the following reactions:
  - (i)  $KNO_3 + FeSO_4 + H_2SO_4(conc.) \longrightarrow ....$
  - (ii)  $Mg + HNO_3 \longrightarrow \dots$
  - (iii)  $Cu + HNO_3 \longrightarrow NO + \dots + \dots$
  - (iv)  $Pb(NO_3)_2 \xrightarrow{\text{Heat}} PbO + \dots + \dots$
  - (v)  $CuSO_4 + NH_4OH(excess) \longrightarrow .....$
  - (vi)  $NH_3(excess) + Cl_2 \longrightarrow \dots + \dots$
  - (vii)  $NH_3 + Cl_2(excess) \longrightarrow \dots$
  - (viii) AgCl + NH<sub>4</sub>OH  $\longrightarrow$  ......
  - (ix)  $Ag(NH_3)_2Cl + HNO_3 \longrightarrow \dots$
  - (x)  $Ca_3(PO_4)_2 + SiO_2 + C \xrightarrow{Heat} CaSiO_3 + CO + \dots$
  - (xi)  $CaCN_2 + H_2O(steam) \longrightarrow CaCO_3 + \dots$
  - (xii)  $Ca_3(PO_4)_2 + H_3PO_4 \longrightarrow \dots$
  - (xiii)  $NH_3 + NaOCl \longrightarrow ..... + NaCl + H_2O$  [I.I.T. 1993]
  - (xiv)  $P_4O_{10} + PCl_5 \longrightarrow \dots$  [I.I.T. 1998]

#### 8. What happens when?

- (i) A mixture of air and ammonia is passed over heated platinum gauze. [M.L.N.R. 1990]
- (ii) Gold is treated with aqua-regia.
- [LLT. 1997]
- (iii) Water is added to calcium phosphide.
- (iv) Calcium phosphate is heated with a mixture of sand and carbon.
- (v) Phosphorus reacts with nitric acid to give equimolar ratio of nitric oxide and nitrogen dioxide.
- (vi) Zinc is treated with very very dilute nitric acid.
- (vii) Phosphine is treated with an acidified CuSO<sub>4</sub> solution. [M.L.N.R. 1990]
- (viii) Iodine reacts with concentrated nitric acid.

[M.L.N.R. 1992]

- (ix) Orthophosphoric acid is heated with nitric acid and ammonium molybdate.
- (x) Disodium hydrogen phosphate is added to ammonical solution of magnesium sulphate.
- (xi) Magnesium is burnt in air and the product is treated with water.
- (xii) Phosphine is passed through AgNO3 solution.
- (xiii) Phosphoric acid reacts with Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>F. [LI.T. 1998]

#### 9. How will you prepare?

- (i) Ammonia from calcium carbide.
- (ii) Nitrogen from ammonium chloride.
- (iii) Phosphine from phosphorus.

- (iv) Phosphorus from bone ash.
- (v) Nitrous oxide from dilute nitric acid.
- (vi) Nitrogen dioxide from concentrated nitric acid.
- (vii) Ammonium nitrate from nitric acid.
- (viii) Yellow phosphorus from orthophosphoric acid.
- (ix) Metaphosphoric acid from orthophosphoric acid.
- (x) Hydrogen from nitric acid.

#### 10. Answer the following:

- (i) How many unpaired electrons are present in the valency shell of VA group elements?
- (ii) How many covalent bonds nitrogen can form?
- (iii) What are the minimum and maximum oxidation states of nitrogen?
- (iv) Which oxyacid of nitrogen behaves both as an oxidising and a reducing agent?
- (v) Why NH<sub>3</sub> exists as liquid whereas other hydrides of the same group exist as gases?
- (vi) Which oxide of nitrogen is paramagnetic and coloured?
- (vii) What are the possible oxidation states for nitrogen? Give an example of each.
- (viii) What is the basicity of hypophosphorus acid?
- (ix) Which allotropic form of phosphorus is more active?
- (x) What is the shape of phosphorus molecule?

### 11. Arrange the following as directed:

- (i) N, P, As, Sb and Bi (increasing order of stability of +5 oxidation state)
- (ii) NCl<sub>3</sub>, PCl<sub>3</sub>, AsCl<sub>3</sub>, SbCl<sub>3</sub> and BiCl<sub>3</sub> (order of ease of hydrolysis)
- (iii) NH<sub>3</sub>, PH<sub>3</sub>, AsH<sub>3</sub> and SbH<sub>3</sub> (increasing order of basic nature)
- (iv) NH<sub>3</sub>, PH<sub>3</sub>, AsH<sub>3</sub>, SbH<sub>3</sub> and BiH<sub>3</sub> (increasing order of stability)

#### 12. How will you obtain?

- (a)  $N_2$  from a mixture of  $N_2$  and CO.
- (b) NH<sub>4</sub>Cl from a mixture of NH<sub>4</sub>Cl and KCl.
- (c) Nitrogen from a mixture of N<sub>2</sub> and O<sub>2</sub>.
- (d) NH<sub>3</sub> from a mixture of N<sub>2</sub> and NH<sub>3</sub>.
- (e) PH<sub>3</sub> from a mixture of PH<sub>3</sub> and NH<sub>3</sub>.
- (f)  $N_2$  from a mixture of  $N_2$  and  $CO_2$ .

#### 13. Write down the formulae of the following:

- (i) Sal ammoniac
- (ii) Laughing gas
- (iii) Superphosphate of lime
- (iv) Triple superphosphate
- (v) Nitrophosphate
- (vi) Leuna saltpetre
- (vii) Nitrochalk
- (viii) Sindri fertilizer
- (ix) CAN
- (x) Nitrolim
- 14. (a) Write the two resonance structures of N<sub>2</sub>O that satisfy the octet rule. [1.1.T. 1990; M.L.N.R. 1993]
  - (b) Give the structural formulae of phosphorus acid  $(H_3PO_3)$  and pyrophosphoric acid  $(H_4P_2O_7)$ .

- (c) Draw the structure of P<sub>4</sub>O<sub>10</sub> and identify the number of single and double P—O bonds. [I.I.T. 1996]
- (d) Draw the structure of P<sub>4</sub>O<sub>6</sub> and identify the number of single P—O bonds.
- (e) Write down the Lewis electron dot formula of the following:

NO, N<sub>2</sub>O<sub>5</sub>, HNO<sub>2</sub>, HNO<sub>3</sub>, PH<sub>4</sub>I, H<sub>3</sub>PO<sub>2</sub>, H<sub>3</sub>PO<sub>4</sub>.

(f) Write down the shapes of the following:

- 15. Write short notes on the following:
  - (a) Nitrogen fertilizers(b) Phosphorus fertilizer
  - (b) Phosphorus fertilizers
  - (c) Mixed fertilizers
  - (d) Action of nitric acid on metals
  - (e) Action of nitric acid on non-metals
  - (f) Nitrogen cycle
  - (g) Nitrogen fixation
  - (h) Oxidation states of nitrogen
  - (i) Oxides of nitrogen
  - (i) Nitrates
  - (k) Holme's signal
  - (l) Uses of nitric acid
  - (m) Passivity
- **16.** Describe the principle of manufacture with conditions of the following compounds:
  - (i) Ammonia by Haber process.
  - (ii) Nitric acid by Ostwald's process.
  - (iii) White phosphorus from bone ash by electrothermic method.
  - (iv) Ammonium sulphate from gypsum. [I.I.T. 1990]
  - (v) Superphosphate of lime.
  - (vi) Nitrolim.
  - (vii) Urea.
- 17. Explain the following with relevent reason:
  - (i) Nitric acid turns yellow in sunlight.

[Ans. HNO<sub>3</sub> decomposes to form yellow N<sub>2</sub>O<sub>4</sub> in sunlight.

$$4HNO_3 \xrightarrow{Sunlight} 2H_2O + 2N_2O_4 + O_2$$

(ii) Why nitrate and nitrite cannot be distinguished by the action of conc. H<sub>2</sub>SO<sub>4</sub>?

[Ans. Because both liberate brown fumes of NO<sub>2</sub> on heating with conc. H<sub>2</sub>SO<sub>4</sub>.]

(iii) Why NO<sub>2</sub> cannot be dried by means of NaOH solution?

[Ans. NO2 is an acidic gas. It is absorbed in NaOH.]

(iv) On heating Pb(NO<sub>3</sub>)<sub>2</sub> produces a pale yellow gas which on strong heating produces a brown gas.

[Ans. Lead nitrate first produces N<sub>2</sub>O<sub>4</sub> which is pale yellow. On further heating, it decomposes into nitrogen dioxide (brown in colour).

$$\begin{array}{c} \text{Pb}(\text{NO}_3)_2 \xrightarrow{\text{Heating}} & \text{N}_2\text{O}_4 \xrightarrow{\text{Heating}} & \text{NO}_2 \\ & \text{A pale} & & \text{A brown} \\ & & \text{yellow gas} & & \text{gas} \end{array}$$

(v) Water has the highest boiling point among NH<sub>3</sub>, PH<sub>3</sub>, HCl and H<sub>2</sub>O.

[Ans. Maximum hydrogen bonding is present in water as oxygen is the most electronegative among N, P, Cl and O.]

(vi) Nitric acid mostly forms oxides of nitrogen on reacting with metals while other acids react with metals to evolve hydrogen.

[Ans. In addition to being an acid, nitric acid is a strong oxidising agent. Before hydrogen is evolved, it reduces nitric acid into nitrogen oxides.]

(vii) Phosphine is prepared in an inert atmosphere of carbon dioxide or hydrogen.

[Ans. Phosphine, being highly inflammable, burns in air. It is therefore prepared in inert atmosphere.]

(viii) Red phosphorus is used for making matches.

[Ans. Red phosphorus is non-poisonous and has a high ignition point.]

(ix) Phosphorus pentoxide is used in the preparation of N<sub>2</sub>O<sub>5</sub>.

[Ans. P<sub>4</sub>O<sub>10</sub> is a strong dehydrating agent. It removes water molecules from nitric acid to form N<sub>2</sub>O<sub>5</sub>.

$$P_4O_{10} + 12HNO_3 \longrightarrow 4H_3PO_4 + 6N_2O_5$$
  
or  $P_4O_{10} + 4HNO_3 \longrightarrow 4HPO_3 + 2N_2O_5$ 

(x) Ammonia is used for refrigeration.

[Ans. Ammonia has high heat of vaporisation.]

(xi) The electronegativity of both nitrogen and chlorine is the same. But nitrogen is inert at room temperature whereas chlorine is highly reactive.

[Ans. Nitrogen molecule consists a strong triple bond whereas a chlorine molecule has only a single bond.]

(xii) Ammonia acts as a ligand.

[Ans. Due to the presence of a lone pair of electrons on nitrogen which it can donate to acceptor (a metal ion) and thus acts as a ligand.]

(xiii) Burning magnesium continues to burn in nitric oxide while burning sulphur is extinguished.

[Ans. The reaction between Mg and O<sub>2</sub> is highly exothermic, *i.e.*, the heat evolved is enough to decompose NO into N<sub>2</sub> and O<sub>2</sub> while the heat evolved during burning of sulphur is not sufficient to break NO.]

(xiv) NF<sub>3</sub> is not hydrolysed but NCl<sub>3</sub> is readily hydrolysed.
[Ans. Neither nitrogen nor fluorine possess vacant d-orbitals to form extra bond with lone pair of electrons on oxygen of water molecule. However, NCl<sub>3</sub> has vacant d-orbitals on chlorine atom.

$$NCl_3 + 3H_2O \longrightarrow NH_3 + 3HClO$$

(xv) Aluminium containers can be used for strong concentrated HNO<sub>3</sub>.

[Ans. Aluminium is rendered passive by conc. HNO<sub>3</sub> due to formation of a fine film of its oxide on its surface. This film does not allow the dissolution of aluminium metal in acid and thus Al-containers can be used to store conc. HNO<sub>3</sub>.]

(xvi) Pure PH<sub>3</sub> does not burn in air but impure sample of PH<sub>3</sub> burns in air.

[Ans. P<sub>2</sub>H<sub>4</sub>, the liquid hydride is always present in impure phosphine. It catches fire as soon as it comes in contact with air.]

(xvii) Phosphorus does not form phosphorus penta-iodide. [Ans. Due to large size of iodine, the effective overlapping between the orbitals of P and I is not possible to form covalent bonds.]

(xviii) Phosphorus acid is a dibasic acid.

[Ans. Phosphorus acid molecule, H<sub>3</sub>PO<sub>3</sub>, possesses two hydroxyl groups, *i.e.*, two replaceable hydrogen atoms.

(xix) Urea is a better nitrogenous fertilizer than ammonium sulphate.

[Ans. Urea on hydrolysis gives NH<sub>3</sub> and CO<sub>2</sub>. NH<sub>3</sub> is assimilated by plants and CO<sub>2</sub> goes to atmosphere, *i.e.*, no residue is left in soil. Ammonium sulphate on hydrolysis gives NH<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub>. NH<sub>3</sub> is assimilated while H<sub>2</sub>SO<sub>4</sub> is retained in soil making it acidic.]

(xx)  $(SiH_3)_3N$  is a weaker base than  $(CH_3)_3N$ . [I.I.T. 1995] [Ans. In  $(SiH_3)_3N$ , the lone pair of electrons on nitrogen is used up in  $p\pi$ - $d\pi$  back bonding. Such a  $p\pi$ - $d\pi$  bonding is not possible in  $(CH_3)_3N$  due to absence of d-orbitals in carbon. This accounts for more basic nature of  $(CH_3)_3N$  than  $(SiH_3)_3N$ .]

(xxi) Mg<sub>3</sub>N<sub>2</sub> when reacted with water gives off NH<sub>3</sub> but HCl is not obtained from MgCl<sub>2</sub> on reaction with water at room temperature. [L.I.T. 1995]

[Ans. MgCl<sub>2</sub> is a salt of a strong acid and a strong base so its hydrolysis is not possible whereas Mg<sub>3</sub>N<sub>2</sub> is a salt of a strong base, Mg(OH)<sub>2</sub>, and a weak acid, NH<sub>3</sub>, so it gets hydrolysed to give NH<sub>3</sub>.]

(xxii) Aqua-regia dissolves gold.

[Ans. Aqua-regia is a mixture of conc. HNO<sub>3</sub> and conc. HCl. Both react to give nascent chlorine which attacks gold and forms gold chloride which dissolves.]

(xxiii) Calcium cyanamide is used as a fertilizer.

[Ans. In soil, it is converted into urea which then decomposes into ammonia. This is assimilated by plants.

$$\begin{array}{c} \text{CaCN}_2 + \text{H}_2\text{O} + \text{CO}_2 & \longrightarrow \text{CN} \cdot \text{NH}_2 + \text{CaCO}_3 \\ & \text{Cyanamide} \\ \\ \text{CN} \cdot \text{NH}_2 + \text{H}_2\text{O} & \longrightarrow \text{NH}_2\text{CONH}_2 \end{array}$$

$$NH_2CONH_2 + H_2O \longrightarrow 2NH_3 + CO_2$$
 ]

(xxiv) Nitric oxide turns brown in air.

[Ans. Nitric oxide directly reacts with oxygen of the air forming brown fumes of  $NO_2$ .

$$2NO + O_2 \longrightarrow 2NO_2$$

(xxv) Copper dissolves in HNO3 but not in HCl.

[Ans. HNO<sub>3</sub> is an oxidising agent which converts copper into CuO which dissolves in HNO<sub>3</sub> in the form of copper nitrate.]

- 18. (i) An inorganic iodide (A) on heating with a solution of KOH gives a gas (B) and the solution of a compound (C).
  - (ii) The gas (B) on ignition in air gives a compound (D) and water.
  - (iii) Copper sulphate is reduced to the metal on passing (B) through the solution.
  - (iv) A precipitate of the compound (E) is formed on reaction of (C) with copper sulphate solution.

Identify (A) to (E) and give chemical equations for reactions at steps (i) to (iv). [Roorkee 1994]

[Hint: Gas (B) on ignition gives water, therefore, hydrogen is present in the gas.

An inorganic iodide with alkali (KOH) gives a gas (B), a hydrogen compound, so (A) may be NH<sub>4</sub>I or PH<sub>4</sub>I. As NH<sub>3</sub> does not reduce CuSO<sub>4</sub>, therefore, the compound (A) is PH<sub>4</sub>I.

(i) 
$$PH_4I + KOH \longrightarrow PH_3 + KI + H_2O$$
  
 $(A)$   $(B)$   $(C)$   
(ii)  $4PH_3 + 8O_2 \longrightarrow P_4O_{10} + 6H_2O$   
 $P_4O_{10} + 2H_2O \longrightarrow 4HPO_3$   
 $(D)$   
Metaphosphoric

(iv) 
$$2\text{CuSO}_4 + 4\text{KI} \longrightarrow \text{Cu}_2\text{I}_2 + 2\text{K}_2\text{SO}_4 + \text{I}_2$$
]  
(C) (E)

19. An orange solid (A) on heating gave a green residue (B), a colourless gas (C) and water vapour. The dry gas (C) on passing over heated magnesium gave a white solid (D). (D) on reaction with water gave a gas (E) which formed dense white fumes with HCl. Identify (A) to (E) and give the reactions.

[I.I.T. 1992]

[Hint: Formation of dense white fumes with HCl indicates that the gas (E) is NH<sub>3</sub>.

Ammonia is formed by hydrolysis of solid (D). Thus, (D) should be  $Mg_3N_2$ .

Formation of (D) indicates that gas (C) is  $N_2$ . Thus, (A) is ammonium dichromate.

$$\begin{array}{cccc} (NH_4)_2Cr_2O_7 & \longrightarrow & N_2 + Cr_2O_3 + 4H_2O \\ \text{Orange (A)} & (C) & \text{Green (B)} \end{array}$$
 
$$3Mg + N_2 & \longrightarrow & Mg_3N_2 \ (D)$$
 
$$Mg_3N_2 + 6H_2O & \longrightarrow & 3Mg(OH)_2 + 2NH_3 \\ NH_3 + HCl & \longrightarrow & NH_4Cl \ ]$$
 Dense white fumes

20. Gradual addition of KI solution to Bi(NO<sub>3</sub>)<sub>3</sub> solution initially produces a dark brown precipitate which dissolves in excess of KI to give a clear yellow solution. Write chemical equations for the above reactions. [LI.T. 1996]

[Hint: Bi(NO<sub>3</sub>)<sub>3</sub> undergoes hydrolysis forming nitric acid. Nitric acid liberates iodine from KI which dissolves in excess of KI giving clear yellow solution.

$$\begin{array}{c} \text{Bi}(\text{NO}_3)_3 \ + \ \text{H}_2\text{O} \ \longrightarrow \ [\text{Bi}(\text{OH})(\text{NO}_3)_2] \ + \ \text{HNO}_3 \\ 2\text{HNO}_3 \ \longrightarrow \ \text{H}_2\text{O} \ + \ 2\text{NO}_2 \ + \ \text{O} \\ 2\text{KI} \ + \ 2\text{HNO}_3 \ + \ \text{O} \ \longrightarrow \ 2\text{KNO}_3 \ + \ \text{H}_2\text{O} \ + \ \text{I}_2 \\ \text{(Dark brown ppt.)} \\ \text{I}_2 \ + \ \text{KI} \ \longrightarrow \ \ \ \ \ \text{KI}_3 \ ] \\ \text{Yellow solution} \end{array}$$

21. A colourless solid (A) liberates a brown gas (B) on acidification, a colourless alkaline gas (C) on treatment with NaOH and a colourless non-reactive gas (D) on heating. If heating of the solid (A) is continued, it completely disappears. Identify (A) to (D).

[Ans. 
$$(A) = NH_4NO_2$$
;  $(B) = NO_2$ ;  $(C) = NH_3$ ;  $(D) = N_2$ ]

22. A compound (A) on heating with an excess of caustic soda solution liberates a gas (B) which gives white fumes on exposure to HCl. Heating is continued to expel the gas completely. The resultant alkaline solution again liberates the same gas (B) with zinc powder. However, the compound (A) when heated alone, does not give nitrogen. Identify (A) and (B).

[Ans. 
$$(A) = NH_4NO_3$$
;  $(B) = NH_3$ ]

- 23. An inorganic compound (A) when heated decomposes completely to give only two gases (B) and (C). (B) is a neutral gas, fairly soluble in water and itself decomposes on heating to two different gases (D) and (E).
  - (A) when warmed with NaOH gives another gas (F) which turns mercurous nitrate paper black. After sometime the gas (F) ceases to evolve, however its supply is restored by treating residual solution with aluminium powder. Identify (A) to (F) and give necessary equations.

$$\begin{array}{c} \text{NH}_4\text{NO}_3 \xrightarrow{\text{Heat}} \text{N}_2\text{O} + 2\text{H}_2\text{O}; \\ 2\text{N}_2\text{O} \xrightarrow{\text{Heat}} 2\text{N}_2 + \text{O}_2 \\ \\ \text{NH}_4\text{NO}_3 + \text{NaOH} \longrightarrow \text{NaNO}_3 + \text{NH}_3 + \text{H}_2\text{O} \\ \\ \text{Al} + \text{NaOH} + \text{H}_2\text{O} \longrightarrow \text{NaAlO}_2 + 3\text{H} \\ \\ \text{NaNO}_3 + 8\text{H} \longrightarrow \text{NaOH} + \text{NH}_3 + 2\text{H}_2\text{O} \\ \end{array}$$

24. In the following reaction,

$$A + 2B + H_2O \longrightarrow C + 2D$$
  
 $(A = \text{HNO}_2, B = \text{H}_2\text{SO}_3, C = \text{NH}_2\text{OH}). \text{ Identify } D.$   
[LI.T. 1999]  
[Ans.  $\text{HNO}_2 + 2\text{H}_2\text{SO}_3 + \text{H}_2\text{O} \longrightarrow \text{NH}_2\text{OH} + 2\text{H}_2\text{SO}_4]$   
(A) (B) (C) (D)

- 25. (i) Sodium salt of an acid (A) is formed on boiling white phosphorus with NaOH solution.
  - (ii) On passing chlorine through phosphorus kept fused under water, another acid (B) is formed which on strong heating gives metaphosphorus acid.
  - (iii) Phosphorus on treatment with conc. HNO<sub>3</sub> gives an acid (C) which is also formed by the action of dilute H<sub>2</sub>SO<sub>4</sub> on powdered phosphorite rock.
  - (iv) (A) on treatment with a solution of HgCl<sub>2</sub> first gives a white precipitate of compound (D) and then a grey precipitate of (E).

Identify (A) to (E) and write balanced equations for the reactions at steps (i) to (iv). [Roorkee 2001] [Hint: (i)  $P_4 + 3NaOH + 3H_2O \longrightarrow$ 3NaH<sub>2</sub>PO<sub>2</sub> + PH<sub>3</sub> Sodium hypophosphite

Thus, acid (A) is H<sub>3</sub>PO<sub>2</sub>, i.e., hypophosphorus acid.

(ii) 
$$2P + 3Cl_2 \longrightarrow 2PCl_3$$
  
 $2PCl_3 + 6H_2O \longrightarrow 2H_3PO_3 + 6HCl_3$ 

$$Ca_3(PO_4)_2 + 3H_2SO_4 \longrightarrow 2H_3PO_4 + 3CaSO_4$$
  
(Phosphorite rock)

(iv) 
$$H_3PO_2 + 2H_2O \longrightarrow H_3PO_4 + 4H$$
  
 $2HgCl_2 + 2H \longrightarrow Hg_2Cl_2 + 2HCl$   
(D)

## Matching Type Questions

#### Match the following:

- [A] (a) Mephitic air
  - (b) Laughing gas

  - (c) Anhydride of HNO<sub>3</sub>
  - (d) Anhydride of HNO<sub>2</sub> (e) Anhydride of HPO<sub>3</sub>
  - (f) Dibasic acid
  - (g) Tribasic acid
  - (h) Acid hydride of nitrogen (viii) Nitrous oxide
  - Basic hydride of nitrogen
  - (j) Brown coloured gas
- [B] (a) CAN
  - (b) NPK
  - (c) Ammonium sulphate
  - (d) Nitrolim
  - (e) Ammonium nitrate
  - Salammoniac
  - (g) Explosive mixture
  - (h) Haber process
  - Ostwald's process (i)
  - Poisonous oxide
  - (k) Leuna saltpetre
  - Nitrochalk

6.

(v)

- (i) Phosphorus acid
- (ii) Hydrazoic acid
- (iii) Orthophosphoric acid
- (iv) Ammonia
- (v) Nitrogen dioxide
- (vi) Nitrogen pentoxide
- (vii) Phosphorus pentoxide
- (ix) Nitrogen
- (x) Nitrogen trioxide
- (i) Freezing salt
- (ii) Manufacture of NH3
- (iii) NH<sub>4</sub>NO<sub>3</sub>+CaCO<sub>3</sub>
- (iv) Arsenious oxide
- (v) Manufacture of HNO<sub>3</sub>
- (vi)  $NH_4NO_3 + (NH_4)_2SO_4$
- (vii) Nangal fertilizer
- (viii) Sindri fertilizer
- (ix) Calcium cyanamide
- (x) Ammonium chloride
- (xi) Mixed fertilizer
- (xii) Amatol

## Answers

#### **Answers**: Subjective Type Questions

- (i) The dissociation energy of nitrogen molecule is very high i.e., 941.4 kJ mol<sup>-1</sup>.
  - (ii) Nitrogen cannot extend its valency from 3 to 5 due to absence of d-orbitals.
  - (iii) BiH3 is least stable as Bi is bigger in size in comparison to the size of hydrogen.
  - (iv) Nitric oxide,  $2NO + O_2 \longrightarrow 2NO_2$ Colourless
  - (v) Nitrous oxide, N2O and nitric oxide, NO
- 2. (i) PCl<sub>3</sub> combines with moisture of air and undergoes hydrolysis giving fumes of HCl.

$$PCl_3 + 3H_2O \longrightarrow H_3PO_3 + 3HCl$$

- (ii) Phosphorus
- (iii) PH<sub>4</sub> ion
- (iv) No, Two axial P-Cl bonds are less stable than three equatorial P-Cl bonds. This is observed when PCl<sub>5</sub> is heated.

$$PCl_5 \longrightarrow PCl_3 + Cl_2$$

- (v) White or yellow, red and black. White phosphorus is most reactive.
- (vi) Freeze
- (a) Due to hydrogen bonding.
  - (b) Due to the presence of odd electron on nitrogen atom.
  - (c) Due to the presence of lone pair of electrons on nitrogen atom which can be donated.
  - (d) NH<sub>3</sub> combines with H<sub>2</sub>SO<sub>4</sub> and forms ammonium sulphate.
  - (e) Hydrogen bonding in NH3 makes it as an associated molecule.
- 4. (a) White phosphorus is more reactive due to higher angular strain in its molecule.

- (b) In hydrazine, there is N—N single bond with lone pair of electrons on each atom. Due to small size of nitrogen, there is considerable repulsion between these non-bonding electrons.
- (c) Because of non-availability of d-orbitals, nitrogen can not accommodate more than 8 electrons in its valence shell and therefore, its trihalides cannot be oxidised to pentahalides.
- (d) Nitric oxide is paramagnetic because of the presence of odd electron. When this electron is lost, NO<sup>+</sup> is formed which is diamagnetic.
- (e) H<sub>3</sub>PO<sub>3</sub> contains one P—H bond and acts as a reducing agent. H<sub>3</sub>PO<sub>4</sub> does not contain P—H bond.
- 5. (i) NH<sub>4</sub>NO<sub>3</sub> (ammonium nitrate); (ii) NH<sub>4</sub>NO<sub>2</sub> (ammonium nitrite); (iii) Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> (calcium phosphate); (iv) NH<sub>2</sub> (ammonia); (v) N<sub>3</sub>H (hydrazoic acid); (vi) N<sub>2</sub>H<sub>4</sub> (hydrazine); (vii) (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> (ammonium sulphate); (viii) NH2OH (hydroxylamine); (ix) N2O and NO; (x) H<sub>3</sub>PO<sub>4</sub> (orthophosphoric acid);

(i) 
$$NH_4NO_3 \longrightarrow N_2O + 2H_2O$$

(ii) 
$$NH_4NO_2 \longrightarrow N_2 + 2H_2O$$

(iii) 
$$NH_4C1 \rightleftharpoons NH_3 + HC1$$

(iv) 
$$\begin{aligned} \text{NaNO}_2 + \text{NH}_4\text{Cl} &\longrightarrow \text{NH}_4\text{NO}_2 + \text{NaCl} \\ \text{NH}_4\text{NO}_2 &\longrightarrow \text{N}_2 + 2\text{H}_2\text{O} \\ \hline \\ \text{NaNO}_2 + \text{NH}_4\text{Cl} &\longrightarrow \text{N}_2 + \text{NaCl} + 2\text{H}_2\text{O} \end{aligned}$$

 $(NH_4)_2Cr_2O_7 \longrightarrow N_2 + Cr_2O_3 + 4H_2O$ 

(vi) 
$$2H_3PO_4 \xrightarrow{250^{\circ}C} H_4P_2O_7 + H_2O$$
  
 $H_3PO_4 \xrightarrow{600^{\circ}C} HPO_3 + H_2O$ 

```
4H_3PO_4 \xrightarrow{\text{Red hot}} P_4O_{10} + 6H_2O
                                4H_3PO_3 \longrightarrow 3H_3PO_4 + PH_3
       (vii)
      (viii)
                                2H_3PO_2 \longrightarrow H_3PO_4 + PH_3
                            2Cu(NO_3)_2 \longrightarrow 2CuO + 2NO_2 + O_2
        (ix)
                               2AgNO_3 \longrightarrow 2Ag + 2NO_2 + O_2
         (x)
 7.
         (i)
                    2KNO_3 + H_2SO_4 \longrightarrow 2HNO_3 + K_2SO_4
                                 2HNO_3 \longrightarrow 2NO + H_2O + 3O
              [2FeSO_4 + H_2SO_4 + O \longrightarrow Fe_2(SO_4)_3 + H_2O] \times 3
                         [FeSO_4 + NO \longrightarrow FeSO_4 \cdot NO] \times 2
     2KNO_3 + 8FeSO_4 + 4H_2SO_4 \longrightarrow
                               3Fe_2(SO_4)_3 + 2FeSO_4 NO + K_2SO_4 + 4H_2O
                         Mg + 2HNO_3 \longrightarrow Mg(NO_3)_2 + H_2
         (ii)
                                 2HNO_3 \longrightarrow H_2O + 2NO + 3O
        (iii)
                 3Cu + 3O + 6HNO_3 \longrightarrow 3Cu(NO_3)_2 + 3H_2O
                        3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O
                             2Pb(NO_3)_2 \longrightarrow 2PbO + 4NO_2 + O_2
        (iv)
         (v)

**Answers : Matching Type Questions** 

## ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. Ammonium nitrate is formed in:
  - (a)  $Zn + v.dil. HNO_3 \longrightarrow$
- (b) Fe + v.dil. HNO<sub>3</sub> $\longrightarrow$
- (c) Sn + dil.  $HNO_3 \longrightarrow$
- (d) All

Ans. (d)

[Hint:  $4M + 10HNO_3 \longrightarrow 4M(NO_3)_2 + NH_4NO_3 + 3H_2O$ ]

- 2. A diatomic gas will be obtained in:
  - (a)  $KNO_3 + K \xrightarrow{Heat}$
- (b)  $NH_4NO_3 \xrightarrow{Heat}$

(c) both

(d) none

Ans. (a)

[Hint:  $2KNO_3 + 10K \longrightarrow 6K_2O + N_2$ ;  $NH_4NO_3 \longrightarrow N_2O + 2H_2O$ ]

Consider the following reaction,

$$NO_2 + NaOH \longrightarrow (A) + (B) + H_2O$$

which of the following is correct?

- (a) both (A) and (B) on heating with Na form  $N_2$
- (b) both (A) and (B) on treatment with Zn and NaOH produce NH<sub>3</sub>
- (c) both are correct
- (d) none is correct

Ans. (c)

[Hint:  $2NO_2 + 2NaOH \longrightarrow NaNO_3 + NaNO_2 + H_2O$ ; (A) (B)  $2NaNO_3 + 10Na \longrightarrow 6Na_2O + N_2$ ;  $NaNO_3 + 8H \xrightarrow{Zn/NaOH} NaOH + NH_3 + 2H_2O$ ;  $2NaNO_2 + 6Na \longrightarrow 4Na_2O + N_2$ ;  $NaNO_2 + 6H \xrightarrow{Zn/NaOH} NaOH + NH_3 + H_2O$ ]

- **4.** Ammonia will be obtained in :
  - (a)  $CaCN_2 + H_2O \longrightarrow$
- (b)  $NH_4H_2PO_4 \xrightarrow{Heat}$
- (c) both
- (d) none

Ans. (c)

[Hint:  $CaCN_2 + 3H_2O \longrightarrow CaCO_3 + 2NH_3$ ;  $NH_4H_2PO_4 \longrightarrow NH_3 + HPO_3 + H_2O$ ]

- 5.  $\text{NaH}_2\text{PO}_4 \xrightarrow{230^{\circ}\text{C}} \text{Na}_3(\text{P}_3\text{O}_9) \xrightarrow{640^{\circ}\text{C}} (\text{NaPO}_3)_n \rightarrow (D)$ compound (D) is:
  - (a) Bunsen's salt
- (b) Graham's salt
- (c) Reimann's salt
- '(d) Werner's salt

Ans. (b)

[ 'int: (D) is sodium hexametaphosphate, (NaPO<sub>3</sub>)<sub>6</sub>, which is called Graham's salt.]

- **6.** The compound  $(SiH_3)_3N$  is expected to be:
  - (a) pyramidal and more basic than (CH<sub>3</sub>)<sub>3</sub>N
  - (b) planar and less basic than (CH<sub>3</sub>)<sub>3</sub>N
  - (c) pyramidal and less basic than (CH<sub>3</sub>)<sub>3</sub>N
  - (d) planar and more basic than (CH<sub>3</sub>)<sub>3</sub>N

Ans. (b)

[Hint:  $(SiH_3)_3N$  is planar and less basic than  $(CH_3)_3N$  because lone pair of N atom is used to form  $d\pi - p\pi$  back bonding with Si-atom.]

- 7. Which one of the following compounds on strong heating evolves ammonia gas?
  - (a)  $(NH_4)_2Cr_2O_7$
- (b) NH<sub>4</sub>NO<sub>3</sub>
- (c) NH<sub>4</sub>NO<sub>2</sub>
- (d)  $(NH_4)_2SO_4$

Ans. (d)

[Hint:  $(NH_4)_2Cr_2O_7 \longrightarrow N_2$ ;  $NH_4NO_3 \longrightarrow N_2O$ ;  $NH_4NO_2 \longrightarrow N_2$ ;  $(NH_4)_2SO_4 \longrightarrow NH_3$ ]

8.  $H_3PO_4 \xrightarrow{250^{\circ}C} (X)$ 

(X), (Y) and (Z) are:

- (a) H<sub>4</sub>P<sub>2</sub>O<sub>7</sub>, HPO<sub>3</sub> and P<sub>4</sub>O<sub>10</sub>
- (b)  $HPO_3$ ,  $H_4P_2O_7$  and  $P_4O_{10}$
- (c) H<sub>4</sub>P<sub>2</sub>O<sub>6</sub>, H<sub>3</sub>PO<sub>3</sub> and P<sub>4</sub>O<sub>6</sub>
- (d) H<sub>4</sub>P<sub>2</sub>O<sub>6</sub>, HPO<sub>3</sub> and P<sub>4</sub>O<sub>6</sub>

Ans. (a)

[Hint: 
$$H_3PO_4 \xrightarrow{250^{\circ}C} H_4P_2O_7 \xrightarrow{600^{\circ}C} HPO_3 \xrightarrow{strongly} P_4O_{10}$$
]

- 9. Solid PCl<sub>5</sub> exists as:
  - (a) dimer P<sub>2</sub>Cl<sub>10</sub>
- (b) [PCl<sub>4</sub>]<sup>+</sup> [PCl<sub>6</sub>]
- (c)  $(PCl_3)(Cl_2)$
- (d) PCl<sub>5</sub> as such

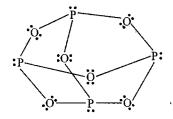

Ans. (b)

- 10. How many P—O bonds and how many lone pairs respectively are present in P<sub>4</sub>O<sub>6</sub> molecule?
  - (a) 12,4

- (b) 8, 8
- (c) 12, 16
- (d) 12, 12

Ans. (c)

[Hint: The structure of P<sub>4</sub>O<sub>6</sub> is the number of P—O bonds and lone pairs are shown. These are 12 and 16 respectively.]

- 11. Which of the following metals, Fe, Zn, Pb, Ag and Pt do not give metal nitrate on treatment with concentrated HNO<sub>3</sub>?
  - (a) Fe and Zn
- (b) Fe and Pt
- (c) Pb, Ag and Pt
- (d) Fe, Ag and Pt

Ans. (b)

- 12. The correct order of bond angle of NO<sub>2</sub><sup>+</sup>, NO<sub>2</sub> and NO<sub>2</sub><sup>-</sup> is: [J.E.E. (Orissa) 2006; C.B.S.E. 2008]
  - (a)  $NO_2^+ < NO_2 < NO_2^-$
- (b)  $NO_2^+ = NO_2^- < NO_2$
- (c)  $NO_2^+ > NO_2 > NO_2^-$
- (d)  $NO_2^+ > NO_2 < NO_2^-$

Ans. (c)

[Hint:

- 13. Which of the following halides is most acidic?
  - (a) PCl<sub>3</sub>

(b) SbCl<sub>3</sub>

(c) BiCl<sub>3</sub>

(d) CCl<sub>4</sub>

Ans. (a)

[Hint: In CCl<sub>4</sub>, carbon atom does not have *d*-orbitals to accommodate a lone pair of electrons and hence is not a Lewis acid. In PCl<sub>3</sub>, SbCl<sub>3</sub> and BiCl<sub>3</sub> central atom has empty *d*-orbitals in each case but electronegativity of P is maximum, hence PCl<sub>3</sub> is strongest acid.]

- 14. Among the following ions,  $p\pi d\pi$  overlap is present in:
  - (a) NO<sub>3</sub>

- (b)  $PO_4^{3}$
- (c)  $CO_3^{2-}$

(d)  $NO_2^-$ 

Ans. (b)

# **OBJECTIVE QUESTIONS**

-				
	_			

**Set I**: This set contains questions with single correct answer.

1.	Which one of the following pairs is obtained on heating		(a) it brings tears to eyes			
	ammonium dichromate? [J.E.E. (W.B.) 2008]		(b) it has high vapour pressure			
	(a) $N_2$ and $H_2O$ $\square$ (b) $N_2O$ and $H_2O$ $\square$		(c) it is corrosive liquid			
	(c) $NO_2$ and $H_2O$ $\square$ (d) $NO$ and $NO_2$ $\square$		(d) it is mild explosive			
2.	By mixing ammonium chloride to potassium nitrite and	14.	Which one of the following oxides of nitrogen is a colo	ured		
	heating, we get: (a) ammonium nitrate $\Box$ (b) KNH <sub>4</sub> (NO <sub>3</sub> ) <sub>2</sub> $\Box$		gas? (a) N <sub>2</sub> O <sub>2</sub>	П		
	(c) nitrogen $\Box$ (d) nitrogen dioxide $\Box$		(a) $N_2O_2$			
2	The salt which on heating gives a mixture of two gases is:	15.				
Э.	(a) NaNO <sub>3</sub>	15.	(a) NaH <sub>2</sub> PO <sub>2</sub>			
	(a) Nativo <sub>3</sub> $\Box$ (b) $Rivo_3$ $\Box$ (c) $Pb(NO_3)_2$ $\Box$ (d) $NH_4NO_3$ $\Box$		(a) $NaH_2PO_2$ $\Box$ (b) $NaH_2PO_3$ (c) $NaH_2PO_4$ $\Box$ (d) $Na_2HPO_4$			
1	Atomicity of phosphorus is:	16	Ammonia reacts with Nessler's reagent to give:	<b></b>		
ч.	(a) 1	10.	(a) deep blue precipitate $\square$ (b) white precipitate			
-	(c) 3		(c) green precipitate $\Box$ (d) brown precipitate	=		
5	Superphosphate of lime is:	17.				
٠.		1	present in solution is:	auon		
	7 3 7/2 7		(a) $Ag^+$			
	(b) $Ca(H_2PO_4)_2$		(c) $[Ag(NH_3)_2]^+$			
	(c) $Ca(H_2PO_4)_2 \cdot CaSO_4$	18.	When NH <sub>4</sub> OH is added to copper sulphate solution,	***		
	(d) $Ca(H_2PO_4)_2 \cdot H_2O \cdot 2CaSO_4 \cdot 2H_2O$		colour is obtained due to formation of:			
6.	Laughing gas is:		(a) $Cu(NH_3)_4SO_4$ $\Box$ (b) $Cu(NH_4SO_4)_2$			
	(a) NO $\Box$ (b) N <sub>2</sub> O $\Box$		(c) Cu(OH) <sub>2</sub>			
	(c) $N_2O_3$ $\square$ (d) $N_2O_5$ $\square$	19.	· · · · · · · · · · · · · · · · · · ·			
7.	Nitrous oxide is prepared in the laboratory by:		(a) precipitate of yellow colour is formed			
	(a) combination of nitrogen and oxygen $\Box$		(b) phosphorus gets free			
	(b) reduction of NO □		(c) oxide of nitrogen is formed			
	(c) reduction of nitric acid $\Box$		(d) ammonia is evolved			
	(d) thermal decomposition of $NH_4NO_3$	20.	Phosphorus is manufactured by heating in an electric fun	nace		
8. Ammonia is not used:			the mixture of:			
	(a) an anaesthesia		(a) bone ash and coke			
	(b) in medicine	1	(b) bone ash and silica			
	(c) in cold storages		(c) bone ash, silica and coke			
	(d) for preparation of artificial silk		(d) bone ash, NaCl and coke			
9.	Which one of the following is used for drying of ammonia?	21.	Which one of the compound is not known?	_		
	(a) conc. $H_2SO_4$ $\square$ (b) CaO $\square$ (c) $P_2O_5$ $\square$ (d) anhydrous $CaCl_2$ $\square$	1	(a) $NCl_5$			
10	(c) $P_2O_5$ $\square$ (d) anhydrous $CaCl_2$ $\square$ Phosphorus is kept in:	1 22	(c) AsCl <sub>5</sub> $\square$ (d) NCl <sub>3</sub>			
10.	(a) kerosene	22.	Nitrolim is obtained by passing nitrogen over:	<b></b>		
	(c) water		<ul><li>(a) heated mixture of Al<sub>2</sub>O<sub>3</sub> and carbon</li><li>(b) carborundum</li></ul>			
11.		1	• •			
	(a) $N_3H$ $\Box$ (b) $N_2H_4$ $\Box$	23.	(c) calcium carbide	<u></u>		
	(c) NH <sub>3</sub> $\square$ (d) N <sub>4</sub> H <sub>4</sub> $\square$	23.	(a) AsH <sub>3</sub>			
12.	Which one of the following is not used for the manufacture		(a) $Asi i 3$ $\Box$ (b) $Asi i 3$ (c) $H_2O$ $\Box$ (d) $PH_3$			
	of ammonia?	24	A certain element forms a solid oxide which dissolv			
(a) Haber process			water to form an acidic solution. The element is:	V3 III		
	(b) Cyanamide process		(a) S			
	(c) Ammonical mother liquor		(c) Na $\square$ (d) P			
	(d) Solvay ammonia process	25.				
13. It is recommended that ammonia bottles be opened after			with air. The gas X is:			
	cooling in ice for sometime. This is because:		(a) NH <sub>3</sub>			
		1	(c) $N_2O$ $\square$ (d) $NO_2$			

26.	Which one of the following is used as anaesthetic?	41.	Amongst the trihalides of nitrogen, which one is least ba	asic?
	(a) $NH_3$ $\Box$ (b) $N_2O$ $\Box$		(a) $NF_3$	
	(c) NO $\Box$ (d) NO <sub>2</sub> $\Box$		(c) $NBr_3$	
27.	The catalyst used in the manufacture of ammonia by Haber	42.	Which one of the following is the strongest base?	
	process is:	ŀ	(a) $AsH_3$ $\Box$ (b) $SbH_3$	
	(a) Pt $\Box$ (b) Fe $\Box$		(c) $PH_3$ $\square$ (d) $NH_3$	
	(c) Mo $\Box$ (d) $V_2O_5$ $\Box$	43.	Skin becomes yellow in conc. HNO <sub>3</sub> because:	
28.	The catalyst used in the manufacture of NO by Ostwald's	1	(a) the proteins are converted into xanthoproteins	
٠,	process is:		(b) HNO <sub>3</sub> acts as a dehydrating agent	$\Box$
•	(a) Pt		(c) nitrocellulose is formed	
	(c) Mo		(d) HNO <sub>3</sub> acts as an oxidising agent	
29.	The correct order of acidic nature of oxides is:		The number of P-O-P and P-OH bonds pro	esent
	(a) $N_2O_5 < N_2O_3 < NO_2 < NO < N_2O$	1	respectively in pyrophosphoric acid molecule are:	
	(b) $N_2\Theta < N\Theta < N_2O_3 < N\Theta_2 < N_2O_5$		(a) 2,2(b) 1,8	
	(c) $N_2O_5 < N_2O < N_2O_3 < NO < NO_2$	1	(c) $1,4$ $\Box$ (d) $1,2$	
	(d) $NO < N_2O < N_2O_3 < NO_2 < N_2O_5$	45.	Nitrates of all metals are:	
30.	Nitrogen dioxide cannot be obtained by heating:		(a) insoluble in water	
50.	(a) KNO <sub>3</sub>		(c) unstable	
•	(c) $Ca(NO_3)_2$	46.	A gaseous mixture contains O <sub>2</sub> and N <sub>2</sub> in the ratio of 1:	4 by-
31.	Ammonia solution dissolves fairly:	1	mass. The ratio of their molecules is:	•
51.	•		(a) 1:4	
	(a) $Hg_2Cl_2$ $\square$ (b) $PbCl_2$ $\square$ (c) $AgI$ $\square$ (d) $Cu(OH)_2$ $\square$		(c) 3:6	
32.	When ammonia is heated with CO <sub>2</sub> under pressure, the	47.	Which of the following will combine with Fe (II) ion to	form
32.	. <del>-</del>		a brown complex compound?	
	product is: (a) $(NH_4)_2CO_3$ $\square$ (b) $NH_2CONH_2$ $\square$		(a) $N_2O$ $\square$ (b) $NO$	
	(a) $(NH_4)_2CO_3$ $\square$ (b) $NH_2CONH_2$ $\square$ (c) $NH_2COONH_4$ $\square$ (d) $NH_4HCO_3$ $\square$		(c) $N_2O_3$ $\square$ (d) $NO_2$	
22		48.	Red phosphorus is made by heating yellow phosphorus	us in
33.	The percentage of nitrogen in urea is about:		the presence of an inert gas at temperature:	
	(a) 70		(a) 60°C	
24	(c) 47		(c) 240°C	
<i>5</i> 4.	A white precipitate is obtained on hydrolysis of:	49.	Phosphorus is used in:	
	(a) $PCl_5$	1	(a) photography	
25	(c) $BiCl_3$ $\Box$ (d) $AsCl_3$ $\Box$		(c) tubber industry	
<i>3</i> 3.	Industrial preparation of nitric acid by ostwald's process	50.	When phosphine is bubbled through a solution of s	ilver
	involves:		nitrate, is precipitated.	
	(a) oxidation of NH <sub>3</sub> $\square$ (b) reduction of NH <sub>3</sub> $\square$	1	(a) silver	
0.0	(c) hydrogenation of NH <sub>3</sub> □ (d) hydrolysis of NH <sub>3</sub> □		(c) silver oxide $\Box$ (d) none of these	
36.	When treated with nitric acid which of the following liberates	51.	When orthophosphoric acid is heated at 240°C, the	main
	hydrogen?		product formed is:	
	(a) zinc		(a) $HPO_3$ $\Box$ (b) $H_3PO_2$	
<b>~=</b>	(c) magnesium		(c) $H_3PO_3$ $\Box$ (d) $H_4P_2O_7$	
37.	Concentrated nitric acid oxidises cane sugar to:	52.	Complete manure is that which supplies:	
	(a) $CO_2$ and $H_2O$ $\square$ (b) $CO$ and $H_2O$ $\square$		(a) $S$ , $K$ and $N$ $\square$ (b) $N$ , $K$ and $P$	
	(c) CO, CO <sub>2</sub> and H <sub>2</sub> O $\square$ (d) oxalic acid and water $\square$		(c) S and N	
38.	White phosphorus reacts with caustic soda. The products	53.	Superphosphate of lime is obtained by treating:	
	are PH <sub>3</sub> and NaH <sub>2</sub> PO <sub>2</sub> . This reaction is an example of:		(a) calcium phosphate with HCl	
	[B.H.U. 2007]		(b) calcium phosphide with HCl	
	(a) oxidation $\square$ (b) reduction $\square$		(c) calcium phosphate with H <sub>2</sub> SO <sub>4</sub>	
	(c) neutralisation $\Box$ (d) disproportionation $\Box$		(d) calcium phosphate with NaOH	
39.		54.	PH <sub>3</sub> produces smoky rings when it comes in contact	with
	(a) sublimation $\Box$ (b) distillation $\Box$	4	air. This is because:	
	(c) dissolving in $CS_2$ $\square$ (d) heating in air $\square$		(a) it is inflammable	
40.	Which one of the acids is a dibasic acid?	i	(b) it combines with water vapour	
	[P.E.T. (Kerala) 2010]		(c) it combines with nitrogen	
	(a) $H_3PO_3$ $\Box$ (b) $H_3PO_2$ $\Box$		(d) it contains impurity of P <sub>2</sub> H <sub>4</sub>	
	(c) $HPO_2$ $\Box$ (d) $H_2PO_4$ $\Box$	1	<del>-</del> ·	

55.	The metal which becomes passive in contact with con	c.		(c) conc. $HNO_3 + NO_2$	
	HNO <sub>3</sub> is:	_		(d) conc. $HNO_3 + conc. H_2SO_4$	
			68.	The number of steps, in which orthophosphoric acid	1 1S
~~	( )			ionised, are:	
56.	Which gas is obtained when urea reacts with nitrous acid			(a) 1	
	\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \		60	(c) 3	Ц
			69.	Phosphorus is usually extracted from:	
57.	Nitrogen percentage is the highest in the fertilizer:			(a) phosphorite	
	•		70	(c) chlorapatite	ш
	( )		/0.	PCl <sub>5</sub> is kept in well stoppered bottles because:	
58.	When zinc reacts with very dilute nitric acid it produces:	_	ļ	<ul><li>(a) it is highly volatile</li><li>(b) it reacts readily with moisture</li></ul>	
	· · · · · · · · · · · · · · · · · · ·			(c) it reacts with oxygen $\Box$ (d) it is explosive	
=0	(-) <u>L</u>		71.		ш
59.	Which of the following-properties-of-white phosphorus a	re		(a) $P_2O_3$ $\square$ (b) $P_2O_4$	
	shared by red phosphorus?			(a) $1_{2}O_{3}$	
			72	Phosphate + conc. HNO <sub>3</sub> + (NH <sub>4</sub> ) <sub>2</sub> MoO <sub>4</sub> soln. $\longrightarrow$ Yell	
			/2.	precipitate. The composition of yellow precipitate is:	IOW
	2				- [7]
	· · · · · · · · · · · · · · · · · · ·		1		ᆸ
60.	The number of P—O—P bridges in the structure of P <sub>4</sub> O	10	72	(c) $(NH_4)_2PO_4\cdot 12MoO_3$ $\square$ (d) $NH_4PO_4\cdot MoO_3$	
	and P <sub>4</sub> O <sub>6</sub> are respectively:		13.	Which one of the materials is not used as a fertilizer	roi
				phosphorus?	<del></del>
				(a) Superphosphate of lime	
61.	Arsenic is detected by:	_		(b) Phosphatic slag	
	_ ``			(c) Guano	
			74	(d) Phosphorite mineral	
62.	Nitrogen molecule is chemically less active because of its		/4.	Which one of the following statements is wrong?	
	83			(a) Ammonia is more poisonous than phosphine	
				(b) Ammonia is more basic than phosphine	
	., 0			(c) Ammonia is more stable than phosphine	
62	(d) stable electronic configuration Which of the following statements is not true?	ш	75	(d) Ammonia is more soluble in water than phosphine	41
05.	(a) Nitrogen differs markedly from the other members of	ita	/5.	One of the acids listed below is formed from P <sub>2</sub> O <sub>3</sub> and	
	- · · · · · · · · · · · · · · · · · · ·			rest are formed from $P_2O_5$ . The acid formed from $P_2O_3$ is	
	•			(a) HPO <sub>3</sub>	
	(c) Nitrogen does not show a greater covalency than thr		76	(c) H <sub>3</sub> PO <sub>4</sub>	ш
	•		/0.	Concentrated nitric acid reacts with iodine to give:  (a) HI	
				(c) $HOIO_2$ $\Box$ (d) $HOIO_3$	
64.	Liquid ammonia is used in refrigerators because:		77.		
	<u> </u>		'''	(a) $SO_4^2$ $\Box$ (b) $SO_3$	
				(a) $50_4$	
				[Hint: $HNO_3 + H_2SO_4 \longrightarrow NO_2^+ + HSO_4^- + H_2O$ ]	
			78.	The reaction between $NH_2$ and $N_2O$ gives :	
65.	The yellow colour often shown by nitric acid can	be	"	(a) NO $\square$ (b) $N_2O_5$	
	removed by:			(c) $NH_2NH_2$ $\square$ (d) $N_3^-$	
	-			[Hint: $NH_2^- + N_2O \longrightarrow N_3^- + H_2O$	
				$NaNH_2 + H_2O \longrightarrow NaOH + NH_3$	
	(c) passing ammonia through acid		79.	,	orus
	(d) adding a little Mg powder			because:	
66.		ast		(a) its colour is red	
	number of moles of KOH?			(b) it is highly polymerised	
	(a) $H_3PO_4$			(c) it is tetratomic	
	$\Box$ (c) $H_3PO_3$ $\Box$ (d) $H_3PO_2$			(d) it is hard	
67.	Aqua-regia is:		80.		iride
*	(a) conc. $HNO_3 + 2$ conc. $HCl$	□.		of nitrous acid?'	
	(b) conc. $HNO_2 + 3$ conc. $HCI$	П	1	•	

	(a) NO	☐ (b) N <sub>2</sub> O <sub>3</sub>		94.	Which of the following f	luorides does not exist?	
	1 7	$\square  \text{(d) } N_2O_5$			(a) NF <sub>5</sub>	□ (b) PF <sub>5</sub>	П
81.		rihalide cannot be hydrolysed?			(c) AsF <sub>5</sub>	$\square  \text{(d) SbF}_5$	
01.	•	☐ (b) PCl <sub>3</sub>		95.	· · ·	over heated CuO, it is oxidised	
	· ·	☐ (d) SbCl <sub>3</sub>		10.	(a) HNO <sub>2</sub>	☐ (b) N <sub>2</sub> O	п.
	/-> ···	oond is stronger than P—O bond.	- 1		(a) 11NO <sub>2</sub> (c) N <sub>2</sub>	$\Box  (d) \text{ NO}_2$	
82.		pitals in the valence shell of ph		96.	· · · -		
OZ.	phorus is:	nais in the valence shell of pi	103-	90.		e isoelectronic. But in contrass	1 10
	(a) 5	□ (b) 3			CN, N <sub>2</sub> is chemically inc	en because or:	
		□ (d) 0			(a) low bond energy	•.	
	(c) 2	□ (a) 0			(b) absence of bond pola		
റാ	[Hint: 5d-orbitals]				(c) unsymmetrical electro		
83.	Which of the following is				<del>-</del>	number of electrons in bond	
	(a) N <sub>3</sub> H	$\square  \text{(b) } N_2H_4$			orbitals		
~4		$\square$ (d)_(CH <sub>3</sub> ) <sub>3</sub> N		97		sed on heating:	
84.		osphide on reaction with excess	s of		(a) $NH_4NO_3$	$\square$ (b) KNO <sub>3</sub>	
	water gives:				(c) NaNO <sub>2</sub>	$\square$ (d) Pb(NO <sub>3</sub> ) <sub>2</sub>	
	(a) one mole of phosphir			98.	Which oxide does not ac		
	(b) two moles of phospho				(a) NO	$\square$ (b) NO <sub>2</sub>	
	(c) two moles of phosph					$\square$ (d) $N_2O_5$	
	(d) two moles of phosph			99.	Of the following, which	h has three electron bond in	its
85.	•	to oxygen bonds in $N_2O_5$ is:	_		structure?		
	(a) 3	□ (b) 4			(a) Nitrous oxide	☐ (b) Dinitrogen trioxide	
	(c) 5	□ (d) 6 ', '			(c) Nitric oxide	☐ (d) Nitrogen pentoxide	
	O <sub>2</sub> 1	5 70		100.	When AgNO <sub>3</sub> is heated	strongly, the products formed	are:
	[Hint: $\frac{O_{1}}{2}N \stackrel{3}{=} O \stackrel{4}{=} 1$	v. 1			(a) NO and NO <sub>2</sub>

93.				108.		iven below, the correct decrea	sing
	(a) NCl <sub>3</sub>	☐ (b) PCl <sub>3</sub>			order of acid strength is		
	(c) AsCl-	□ (d) di			(i) H <sub>2</sub> AsO <sub>4</sub> (ii) H <sub>2</sub> SbO	$_4$ (iii) HNO <sub>3</sub> (iv) H <sub>3</sub> PO <sub>4</sub>	

	(a) $(iv) > (iii) > (i)$ (b) $(iii) > (iv) > (i) > (ii)$		120.	A metal X on heating in nitrogen gas gives Y. Y or	n treatment
	(c) $(iii) > (ii) > (iv) > (i)$			with H <sub>2</sub> O gives a colourless gas which when pass	ed through
109.	Among the following oxides, the lowest acidic is:			CuSO <sub>4</sub> solution gives a blue colour. Y is: [D	.C.E. 2000]
	(a) $P_4O_6$			(a) $Mg(NO_3)_2$ $\square$ (b) $Mg_3N_2$	
	(c) $As_4O_6$			(c) NH <sub>3</sub>	
110.	The basic character of the hydrides of Vth group elements		121.	In which of the following the bond angle is max	
	decreases in the order:				.S.E. 2001]
	(a) $NH_3 > PH_3 > AsH_3 > SbH_3$			(a) $NH_3$ $\square$ (b) $NH_4^+$	
	(b) $SbH_3 > AsH_3 > PH_3 > NH_3$			(c) $PCl_3$	ā
	(c) $NH_3 > NBH_3 > PH_3 > AsH_3$		122	Nitrogen forms N <sub>2</sub> but phosphorus is converted in	
	(d) $SbH_3 > PH_3 > AsH_3 > NH_3$		I.LaL.		.S.E. 2001]
111	Solid PCl <sub>5</sub> exists as:	<u></u>		(a) triple bond is present between phosphorus	
111.				(b) $p\pi$ - $p\pi$ bonding is weak	
	(a) $[PCl_4]^+[PCl_6]^ \Box$ (b) dimer $P_2Cl_{10}$			(c) $p\pi$ - $p\pi$ bonding is strong	
	(c) $[PCl_3][Cl_2]$ $\square$ (d) $PCl_5$ as such			(d) multiple bond is formed easily	
112.	Which of the following species is paramagnetic?		122	•	. —
	(a) $O_2^{2-}$		123.	In NO <sub>3</sub> ion, the number of bond pair and lo	ne pan or
	(c) CO $\square$ (d) CN $^{-}$			electrons on nitrogen atoms are:	N.C. 2002]
113.	The BCl <sub>3</sub> is a planar molecule whereas, NCl <sub>3</sub> is pyram	idal		[C.B.S.E. 2002; A.F.	
	because:			(a) 2, 2	
	(a) N—Cl bond is more covalent than B—Cl bond		124	(c) 1,3	
	(b) B—Cl bond is more polar than N—Cl bond		124.	A pale blue liquid which is obtained by reacting	•
	(c) hitrogen atom is smaller than boron				[I.I.T. 2008]
	(d) BCl <sub>3</sub> has no lone pair but NCl <sub>3</sub> has a lone pair of elec	tron		(a) $N_2O_3$	
				(c) $N_2O_4$	
114.	Nitrogen can be purified from the impurities of oxide	s of		[Hint: NO + NO <sub>2</sub> $\xrightarrow{-30^{\circ}\text{C}}$ N <sub>2</sub> O <sub>3</sub> (Pale blue)]	
	nitrogen and ammonia by passing through:		125.	The element which forms oxides in all the oxid	ation states
	(a) a solution of K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> acidified with H <sub>2</sub> SO <sub>4</sub>				.M.S. 2004]
	(b) concentrated HCl			(a) N	o o
	(c) alkaline solution of pyrogallol			(c) As	
	(d) a solution of KOH		126.		
115.	In white phosphorus (P <sub>4</sub> ) molecule which one is not corr		120.		[I.I.T. 2004]
	(a) Six P—P single bonds are present		-	-	[1.1.1. 2004]
	(b) Four P—P single bonds are present			(a) heating NH <sub>4</sub> NO <sub>2</sub>	
	(c) Four lone pairs of electron are present			(b) heating NH <sub>4</sub> NO <sub>3</sub>	
	(d) P P P bond angle is 60°			(c) treating Mg <sub>3</sub> N <sub>2</sub> with H <sub>2</sub> O	
116.	Which of the following is the correct statement for PF		2	(d) heating H <sub>2</sub> O <sub>2</sub> on NaNO <sub>2</sub>	
	(a) It is less basic than NH <sub>3</sub>		127.	Which one of the following oxides of nitrogen	
	(b) It is less poisonous than NH <sub>3</sub>				.M.C. 2004]
	(c) Electronegativity of PH <sub>3</sub> is greater than NH <sub>3</sub>			(a) $NO_2$ $\square$ (b) $N_2O$	
	(d) It does not show reducing properties			(c) $N_2O_3$ $\square$ (d) $N_2O_5$	
117.	The number of P—O—P bonds in cyclic metaphosph	oric	128.	In the electrothermal process, the compound di	
	acid is:	_		silica from calcium phosphate is : [C.E.T. (Karns	ataka) 2004]
	(a) zero $\Box$ (b) two			(a) calcium phosphide	
	(c) three $\Box$ (d) four			(b) phosphine	
118.	The hybridization of atomic orbitals of nitrogen in $NO_2^+$ ,	_		(c) phosphorus	
	and NH <sub>4</sub> are: [L.I.T. (S) 2	<i>(</i> 000]		(d) phosphorus pentoxide	
	(a) $sp$ , $sp^3$ and $sp^2$ respectively		129.	N <sub>2</sub> forms NCl <sub>3</sub> whereas P can form both PCl <sub>3</sub>	and PCl <sub>5</sub> .
	(b) $sp$ , $sp^2$ and $sp^3$ respectively				rissa) 2004]
	(c) $sp^2$ , $sp$ and $sp^3$ respectively			(a) P has d-orbitals which can be used for bond	ling but N <sub>2</sub>
	(d) $sp^2$ , $sp^3$ and $sp$ respectively			does not have	Ī
110		-	1		
119.		20001		(b) N atom is larger than P in size	
119.	Ammonia can be dried by: [I.I.T. (S) 2 (a) conc. $H_2SO_4$ $\square$ (b) $P_4O_{10}$	[000		<ul><li>(b) N atom is larger than P in size</li><li>(c) P is more reactive towards Cl than N</li></ul>	

130.	Which is used to produce smoke screens? [A.F.M.C. 2005]	140.	Match List-I with List-II and select the correct answer:
	(a) Zinc sulphide $\square$ (b) Calcium phosphide $\square$		[J.E.E. (Orissa) 2008]
	(c) Zinc phosphide		List-II List-II
131.	The percentage of p-character in the orbitals forming P-P		(Molecules) (Boiling points)
	bonds in $P_4$ is: [I.I.T. 2007]		(A) $NH_3$ (1) $290 K$
	(a) 25		(B) PH <sub>3</sub> (2) 211 K
	(c) 50		(C) $AsH_3$ (3) $186 K$
132.	Which of the following is the correct order of increasing		(D) SbH <sub>3</sub> (4) 264 K
	enthalpy of vaporisation? [P.M.T. (Kerala) 2007]	}	(E) BiH <sub>3</sub> (5) 240 K
	(a) $NH_3 < PH_3 < AsH_3$ $\square$ (b) $AsH_3 < PH_3 < NH_3$ $\square$		(a) A-3, B-2, C-5, D-4, E-1
		1	(b) A-5, B-3, C-2, D-4, E-1
			(c) A-1, B-4, C-5, D-2, E-3
100	(e) $AsH_3 < NH_3 < PH_3$		(d) A-1, B-2, C-3, D-4, E-5
133.	Chlorine reacts with excess of ammonia to form:	141	Phosphine, acetylene and ammonia ean be formed by
	[P.M.T. (Kerala) 2007]	171.	<u>.</u>
	(a) $NH_4Cl$ $\Box$ (b) $N_2 + HCl$ $\Box$		=
	(c) $N_2 + NH_4Cl$ $\square$ (d) $N_2 + NCl_3$ $\square$		(a) $Mg_3P_2$ , $Al_4C_3$ , $Li_3N$
	(e) $NCl_3 + HCl$		(b) $Ca_3P_2$ , $CaC_2$ , $Mg_3N_2$
134.	The following are some statements related to VA group	l · .	(c) $Ca_3P_2$ , $CaC_2$ , $CaCN_2$
	hydrides,	1.40	(d) $Ca_3P_2$ , $Mg_2C$ , $NH_4NO_3$
	(i) Reducing property increases from NH <sub>3</sub> to BiH <sub>3</sub>	142.	The number of P—O bonds and lone pair of electrons
	(ii) Tendency to donate lone pair decreases from NH <sub>3</sub> to		present in P <sub>4</sub> O <sub>6</sub> molecule are, respectively:
	BiH <sub>3</sub>	}	[E.A.M.C.E.T. 2008]
	(iii) Thermal stability of hydrides decreases from NH <sub>3</sub> to		(a) 12, 16
	$BiH_3$		(c) 8, 8
	(iv) Bond angle decreases from NH <sub>3</sub> to BiH <sub>3</sub>	143.	Hydrolysis of NCl <sub>3</sub> gives NH <sub>3</sub> and X. Which of the following
	The correct statements are: [E.A.M.C.E.T. (Engg.) 2007]		is X? [A.F.M.C. 2008]
	(a) (i), (ii), (iii) and (iv) $\square$ (b) (i), (iii) and (iv) $\square$		(a) HClO <sub>4</sub>
-	(c) (i), (ii) and (iv) $\Box$ (d) (i) and (iv) $\Box$		(c) HClO $\Box$ (d) HClO <sub>2</sub> $\Box$
135.	Which is in the decreasing order of boiling points of	144.	The shape of PCl <sub>3</sub> molecule is: [A.F.M.C. 2008]
	V group hydrides? [E.A.M.C.E.T. (Med.) 2007]		(a) trigonal bipyramidal  (b) tetrahedral
	(a) $NH_3 > PH_3 > AsH_3 > SbH_3$		(c) pyramidal
	(b) $SbH_3 > AsH_3 > PH_3 > NH_3$	145.	Which of the following is not correct? [C.P.M.T. 2008]
	(c) $PH_3 > NH_3 > AsH_3 > SbH_3$		(a) Hydrolysis of NCl <sub>3</sub> gives NH <sub>3</sub> and HClO
	(d) $SbH_3 > NH_3 > AsH_3 > PH_3$		(b) NH <sub>3</sub> is less stable than PH <sub>3</sub>
136.	N <sub>2</sub> O is isoelectronic with CO <sub>2</sub> and N <sub>3</sub> , which is the structure		(c) NH <sub>3</sub> is a weak reducing agent compared to PH <sub>3</sub>
	of $N_2O$ ? [J.E.E. (Orissa) 2007]	1	(d) Nitric oxide in solid state exhibits diamagnetic property
	(a) N	146.	The atomicity of phosphorus is $X$ and the PPP bond angle
	_ · · · · · · · ·		is Y. What are X and Y? [D.C.E. (Engg.) 2008]
	(c) $N^N$ O $\square$ (d) $N_N$ $\square$	1	(a) $X = 4$ , $Y = 90^{\circ}$
137.	The hybridization state of the central atom in PCl <sub>5</sub> is:		(c) $X = 3$ , $Y = 120^{\circ}$
	[D.C.E. (Engg.) 2007]	147.	The reaction of $P_4$ with X leads selectively to $P_4O_6$ . The X
	(a) $sp^3d$		is: [L.I.T. 2009]
	(c) $sp^3$ $\Box$ (d) $d^2sp^3$ $\Box$		(a) a dry O <sub>2</sub>
138.	Cl—P—Cl bond angles in PCl <sub>5</sub> molecule are:		(b) a mixture of $O_2$ and $N_2$
156.	- ·		(c) moist O <sub>2</sub>
	[V.I.T.E.E. 2008]		(d) O <sub>2</sub> in presence of aqueous NaOH
	(a) 120° and 90°		[Hint: N <sub>2</sub> prevents the further reaction of P <sub>4</sub> O <sub>6</sub> into P <sub>4</sub> O <sub>10</sub> .]
120	(c) 60° and 120°	148.	Atoms in P <sub>4</sub> molecule of white phosphorus are arranged
139.	Bond angles of NH <sub>3</sub> , PH <sub>3</sub> , AsH <sub>3</sub> and SbH <sub>3</sub> are in the order:	0.	regularly in the following way: [J.E.E. (W.B.) 2009]
	[J.E.E. (Orissa) 2008]		(a) at the corners of a cube
	(a) $PH_3 > AsH_3 > SbH_3 > NH_3$		(b) at the corners of an octahedron
	(b) $SbH_3 > AsH_3 > PH_3 > NH_3$		// · · · · · · · · · · · · · · · · · ·
	(c) $SbH_3 > AsH_3 > NH_3 > PH_3$	(	(d) at the corners of a tetrahedron (d) at the centre and corners of a tetrahedron
	(d) $NH_3 > PH_3 > AsH_3 > SbH_3$	t .	(a) at the contact and corners of a terraneuron

## **Objective Questions for IIT ASPIRANTS**

- 1. White phosphorus on reaction with limewater gives calcium salt of an acid (A) along with a gas (X). Which of the following is correct?
  - (a) (A) on heating gives (X) and  $O_2$
  - (b) The bond angle in (X) is less than that in case of ammonia
  - (c) (A) is a dibasic acid
  - (d) (X) is more basic than ammonia

[Hint: 
$$8P + 3Ca(OH)_2 + 6H_2O \longrightarrow 3Ca(H_2PO_2)_2 + 2PH_3$$
(X)

- (A) is H<sub>3</sub>PO<sub>2</sub> (Hypophosphorus acid). It is a monobasic acid. PH<sub>3</sub> is less basic than NH<sub>3</sub>. The bond angle in (X) is less than that present in NH<sub>3</sub>. H<sub>3</sub>PO<sub>2</sub> on heating gives orthophosphoric acid and phosphine (X).]
- 2. One mole of H<sub>3</sub>PO<sub>3</sub> on reaction with excess of NaOH gives:
  - (a) one mole of Na<sub>2</sub>HPO<sub>3</sub>
  - (b) two moles of Na<sub>2</sub>H<sub>2</sub>PO<sub>3</sub>
  - (c) two moles of Na<sub>2</sub>HPO<sub>3</sub>
  - (d) one mole of Na<sub>3</sub>PO<sub>3</sub>

[Hint: 
$$H_3PO_3 + 2NaOH \longrightarrow Na_2HPO_3 + 2H_2O$$
]

- 3. A diatomic gas will be obtained in:
  - (a) Cu + dil.  $HNO_3 \longrightarrow$
  - (b)  $(NH_4)_2Cr_2O_7 \xrightarrow{Heat}$
  - (c) both
  - (d) none

[Hint: 
$$3\text{Cu} + 8\text{HNO}_3 \longrightarrow 3\text{Cu}(\text{NO}_3)_2 + 2\text{NO} + 4\text{H}_2\text{O};$$
  
 $(\text{NH}_4)_2\text{Cr}_2\text{O}_7 \longrightarrow \text{N}_2 + \text{Cr}_2\text{O}_3 + 4\text{H}_2\text{O}]$ 

**4.** For NH<sub>2</sub>OH·HCl + NaNO<sub>2</sub>  $\longrightarrow$  (A)  $\xrightarrow{\text{Cu}}$  (B) + (X)<sub>gas</sub>, which of the following is correct?

- (a) (B) is an amphoteric oxide
- (b) (X) is a colourless, diamagnetic gas which combines with Al on heating
- (c) (X) can be produced by action of (Zn + NaOH) on NaNO<sub>2</sub>
- (d) none of the above

[Hint: 
$$NH_2OH \cdot HCl + NaNO_2 \longrightarrow N_2O \xrightarrow{Cu} CuO + N_2 (B) (X)$$
  
CuO is a basic oxide.  $N_2$  is a colourless, diamagnetic gas which combines with Al.  $2Al + N_2 \longrightarrow 2AlN$ .  
 $Zn + NaOH \cdot evolves \cdot H_2 \cdot which reduces \cdot NaNO_2 \cdot to form NH_3 \cdot gas. NaNO_2 + 6H \longrightarrow NaOH + NH_3 + H_2O.]$ 

- 5. If O<sub>2</sub> is removed from the formula of anhydride of HNO<sub>2</sub>, then the formula of the resulting compound satisfies which of the following properties?
  - (a) It produces tears in eyes (b) It supports combustion
  - (c) It is paramagnetic
  - (d) It cannot react with red hot copper
  - [Hint: The anhydride of HNO<sub>2</sub> is N<sub>2</sub>O<sub>3</sub>. If O<sub>2</sub> is removed, then the resulting compound is N<sub>2</sub>O. Nitrous acid does not produce tears in eyes and it is diamagnetic in nature. It supports combustion and reacts with hot copper.]
- 6. Which of the following is correct?
  - (a) N<sub>2</sub>O is a laughing gas and is angular in shape
  - (b) NO2 is a sweet smelling and is angular in shape
  - (c) NO is a colourless gas and acidic in nature
  - (d) NO<sub>2</sub> on reaction with NaOH gives a mixture of two salts

[Hint: N<sub>2</sub>O is a laughing gas and linear in shape. NO<sub>2</sub> is having pungent odour and angular in shape. NO is a colourless and neutral in nature. NO<sub>2</sub> on reaction with NaOH forms two salts NaNO<sub>2</sub> and NaNO<sub>3</sub>.

$$2NaOH + 2NO_2 \longrightarrow NaNO_2 + NaNO_3 + H_2O$$

- 7. When a mixture of NO and NO<sub>2</sub> is passed through an aqueous solution of ammonium sulphate, we get:
  - (a) a dibasic acid which has no dehydrating property
  - (b) a diatomic gas which on reaction with acetylene under electric spark gives a monobasic acid whose anion is pseudohalide
  - (c) a dibasic acid whose dinegative anion has all bonds equal with bond angle 90°
  - (d) a dibasic acid whose anhydride in solid state forms a cyclic trimer

[Hint: NO + NO<sub>2</sub> + (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> + H<sub>2</sub>O 
$$\rightarrow$$
 2NH<sub>4</sub>NO<sub>2</sub>+ H<sub>2</sub>SO<sub>4</sub>  $\downarrow$  2N<sub>2</sub> + 4H<sub>2</sub>O

$$N_2 + C_2H_2 \xrightarrow{\text{Electric}} 2HCN$$
  
CN is a pseudohalide.]

- Copper metal on treatment with dilute HNO3 produces a gas (X). (X) when passed through acidic solution of stannous chloride, a nitrogen containing compound (Y) is obtained. (Y) on reaction with nitrous acid produces a gas (Z). Gas (Z)is:
  - (a) NO

(b)  $N_2$ 

(c) NO<sub>2</sub>

(d)  $N_2O$ 

(c) NO<sub>2</sub> (d) N<sub>2</sub>O  
[Hint: Cu+dil.HNO<sub>3</sub> 
$$\rightarrow$$
 NO  $\xrightarrow{SnCl_2/HCl}$  NH<sub>2</sub>OH·HCl  $\xrightarrow{(Y)}$   $\xrightarrow{HNO_2}$  N<sub>2</sub>O] (Z)

- 9. A tetra-atomic molecule (A) on reaction with nitrogen (I) oxide, produces two substances (B) and (C). (B) is a dehydrating agent while substance (C) is a diatomic gas which shows almost inert behaviour. The substances (A), (B) and (C) are:
  - (a)  $P_4$ ,  $P_4O_{10}$ ,  $N_2$

(b)  $P_4$ ,  $N_2O_5$ ,  $N_2$ 

(c)  $P_4, P_2O_3, Ar$ 

(d)  $P_4, P_2O_3, O_2$ 

[Hint: 
$$P_4 + 10N_2O \longrightarrow P_4O_{10} + 10N_2$$
]

- 10. The number of P—O—P and P—O—H bonds present respectively in pyrophosphoric acid molecule are:
  - (a) 1, 2

(b) 2, 2

(c) 1, 4

(d) 1, 8

[Hint: The structure of pyrophosphoric acid is

There are one P-O-P and four P-O-H bonds.]

- 11. Which of the following is a cyclic oxoacid?
  - (a)  $H_4P_2O_7$

(b)  $H_4P_2O_6$ 

(c)  $H_5P_5O_{15}$ 

(d)  $H_3P_3Q_9$ 

[Hint: H<sub>3</sub>P<sub>3</sub>O<sub>9</sub> is a cyclic trimetaphosphoric acid.

12. The equivalent mass of phosphoric acid (H<sub>3</sub>PO<sub>4</sub>) in the reaction, NaOH +  $H_3PO_4 \longrightarrow NaH_2PO_4 + H_2O_5$ , is:

(a) 25

(b) 49

(c) 59

(d) 98

[Hint: Only one hydrogen atom of H<sub>3</sub>PO<sub>4</sub> is replaced, so its equivalent mass is equal to its molecular mass.]

13. The oxyacid of phosphorus in which phosphorus has the lowest oxidation state is:

(a) hypophosphorus acid

(b) orthophosphoric acid

(c) pyrophosphoric acid

(d) metaphosphoric acid

[Hint: 
$$H_3PO_2$$
, O.S.  $P = +1$ ;  $H_3PO_4$ , O.S.  $P = +5$ ;  $H_4P_2O_7$ , O.S.  $P = +5$ ;  $HPO_3$ , O.S.  $P = +5$ ]

- 14. Which is/are correct statements about P<sub>4</sub>O<sub>6</sub> and P<sub>4</sub>O<sub>10</sub>?
  - (a) Both form oxoacids H<sub>3</sub>PO<sub>3</sub> and H<sub>3</sub>PO<sub>4</sub> respectively
  - (b) In P<sub>4</sub>O<sub>6</sub> each P is joined to three O and in P<sub>4</sub>O<sub>10</sub> each P is linked to four O atoms
  - (c) Both
  - (d) None
- 15. Blue liquid which is formed at -30°C by mixing of two gases is:

(a) N<sub>2</sub>O

(b)  $N_2O_5$ 

(c)  $N_2O_3$ 

(d)  $N_2O_4$ 

[Hint: NO+NO<sub>2</sub>  $\xrightarrow{-30^{\circ}\text{C}}$  N<sub>2</sub>O<sub>3</sub> (Pale blue colour)]

- 16. For H<sub>3</sub>PO<sub>3</sub> and H<sub>3</sub>PO<sub>4</sub>, the correct choice is:
  - (a) H<sub>3</sub>PO<sub>3</sub> is dibasic and reducing
  - (b) H<sub>3</sub>PO<sub>3</sub> is dibasic and non-reducing
  - (c) H<sub>3</sub>PO<sub>4</sub> is tribasic and reducing
  - (d) H<sub>3</sub>PO<sub>3</sub> is tribasic and non-reducing
- 17. The compound molecular in nature in gas phase but ionic in solid state is:
  - (a) PCl<sub>3</sub>

(b) CCl<sub>4</sub>

(c) PCl<sub>5</sub>

(d) POCl<sub>3</sub>

[Hint: PCl<sub>5</sub> exists as [PCl<sub>4</sub>]<sup>+</sup>[PCl<sub>6</sub>] in solid state.]

- 18. The decreasing order of the boiling points of the following hydrides is:
  - (i)  $NH_3$  (ii)  $PH_3$  (iii)  $AsH_3$  (iv)  $SbH_3$  (v)  $H_2O$
  - (a) (v) > (iv) > (i) > (iii) > (ii)
  - (b) (v) > (i) > (ii) > (iii) > (iv)
  - (c) (ii) > (iv) > (iii) > (i) > (v)
  - (d) (iv) > (iii) > (i) > (ii) > (v)

[Hint: B.pts:  $NH_3 = -33^{\circ}C$ ;  $PH_3 = -89^{\circ}C$ ;  $AsH_3 = -63$ ;  $SbH_3 = -9$ ;  $H_2O = 100^{\circ}C$ 

**4.** (b) 1. (b) 3. (c) 5. (b) **6.** (d) 7. (b) 8. (d) **2.** (a) **9.** (a) 10. (c) 11. (d) **12.** (d) 17. (c) 13. (a) 14. (c) 15. (c) 16. (a) 18. (a)

## **Assertion-Reason Type Questions**

The following questions consist of two statements as Assertion (A) and Reason (R). While answering these questions choose correctly any one of the following responses.

- (a) If both (A) and (R) are true and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are true but (R) is not the correct explanation of (A).
- (c) If (A) is true but (R) is false.
- (d) If (A) is false but (R) is true.
- (e) If both (A) and (R) are false.
- 1. (A) HNO<sub>3</sub> is stronger than HNO<sub>2</sub>.
  - (R) In HNO<sub>3</sub> there are two nitrogen to oxygen bonds whereas in HNO<sub>2</sub> there is only one. [I.I.T. 1998]
- 2. (A)  $P_4$  is more reactive than  $N_2$ .
  - (R) P—P single bond is much more weaker as compared toN≡N triple bond.
- 3. (A) Although PF<sub>5</sub>, PCl<sub>5</sub> and PBr<sub>5</sub> are known, the pentahalides of nitrogen have not been observed.
  - (R) Phosphorus has lower electronegativity than nitrogen.
    [I.I.T. 1995]

**4.** (A) Nitrogen is unreactive at room temperature but becomes reactive at elevated temperatures or in presence of a catalyst.

(R) In nitrogen molecule, there is extensive delocalization of electrons. [A.I.I.M.S. 1996]

- 5. (A) PH<sub>3</sub> is more basic than NH<sub>3</sub>.
  - (R) Electronegativity of N is more than phosphorus.
- (A) H<sub>3</sub>PO<sub>3</sub> and H<sub>3</sub>PO<sub>4</sub> are tribasic acids as they contain three hydrogen atoms each.
  - (R) Both H<sub>3</sub>PO<sub>3</sub> and H<sub>3</sub>PO<sub>4</sub> are reducing in nature.
- 7. (A) For drying ammonia gas, the common dehydrating agents like H<sub>2</sub>SO<sub>4</sub>, CaCl<sub>2</sub> or P<sub>2</sub>O<sub>5</sub> cannot be used.
  - (R) H<sub>2</sub>SO<sub>4</sub>, CaCl<sub>2</sub> or P<sub>2</sub>O<sub>5</sub> react with NH<sub>3</sub>.
- 8. (A) Phosphorite mineral cannot be used as a fertilizer of phosphorus.
  - (R) Superphosphate of lime is used as a fertilizer of phosphorus.
- 9. (A) H<sub>3</sub>PO<sub>3</sub> is a dibasic acid.
  - (R) There are two H-atoms directly attached to P.

[A.I.I.M.S. 2007]

# THOUGHT TYPE QUESTIONS

#### THOUGHT 1

Nitrogen, phosphorus and potassium are regarded as essential plant nutrients. After a few years of continuous cultivation, the soil becomes poorer and poorer in materials supplying nitrogen, phosphorus and potassium to plants. If the soil is not compensated, it would become less productive and infertile. In order to maintain soil fertility, it is necessary to add materials containing nitrogen, phosphorus and potassium in the form of fertilizers. Chemical substances which are added to the soil as to make up the deficiency of essential elements are called chemical fertilizers. Every chemical compound of nitrogen, phosphorus and potassium cannot be used as a fertilizer. Substances to be used as fertilizers must have the following characteristics:

- (a) it must be soluble in water
- (b) it should be easily assimilated by plants
- (c) it should be stable
- (d) it should not disturb the pH of the soil
- (e) it should be cheap

The important nitrogeneous fertilizers are:

- (a) ammonium sulphate
- (b) calcium cyanamide

- (c) calcium ammonium nitrate
- (d) urea
- (e) basic calcium nitrate

The important phosphatic fertilizers are:

- (a) calcium superphosphate
- (b) nitrophosphate
- (c) triple phosphate
- (d) phosphatic slag

The commonly used potassium fertilizers are:

- (a) potassium nitrate
- (b) potassium chloride
- (c) potassium sulphate

Fertilizers containing N, P and K in suitable adjusted proportions are known as NPK fertilizers.

- 1. Which one of the following substances is used as a fertilizer?
  - (a)  $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$
  - (b) Ca(CN)<sub>2</sub>
  - (c)  $Ca(H_2PO_4)_2H_2O\cdot 2(CaSO_4\cdot 2H_2O)$
  - (d) CaSO<sub>4</sub>
- 2. Fertilizer having highest percentage of nitrogen is :
  - (a) urea

- (b) calcium cyanamide
- (c) ammonium nitrate
- (d) ammonium sulphate

Elen	nents of Group VA or 15 (E	lements of Nitrogen and Phosp
3.	Sindhri fertilizer is chemical	lv known as :

  - (a) 3, 1

(b) 2, 2

(c) 1; 2

(d) 1, 3

#### THOUGHT 4

There are some deposits of nitrates and phosphates in earth's crust. Nitrates are more soluble in water. Nitrates are difficult to reduce under the laboratory conditions but microbes do it easily. Ammonia forms large number of complexes with transition metal ions. Hybridization easily explains the ease of sigma donation capability of NH<sub>3</sub> and PH<sub>3</sub>. PH<sub>3</sub> is a flammable gas and is prepared from white phosphorus. [I.I.T. 2008]

- 1. Among the following, the correct statement is:
  - (a) Phosphates have no biological significance in humans
  - (b) Between nitrates and phosphates, phosphates are less abundant in earth's crust
  - (c) Between nitrates and phosphates, nitrates are less abundant in earth's crust
  - (d) Oxidation of nitrates is possible in soil
- Among the following, the correct statement is:
  - (a) Between NH<sub>3</sub> and PH<sub>3</sub>, NH<sub>3</sub> is a better electron donor because the lone pair of electrons occupies spherical s-orbital and is less directional.
  - (b) Between NH3 and PH3, PH3 is a better electron donor because the lone pair of electrons occupies sp<sup>3</sup>-orbital and is more directional.
  - (c) Between NH<sub>3</sub> and PH<sub>3</sub>, NH<sub>3</sub> is a better electron donor because the lone pair of electrons occupies  $sp^3$ -orbital and is more directional.
  - (d) Between NH3 and PH3, PH3 is a better electron donor because the lone pair of electrons occupies spherical s-orbital and is less directional.
- White phosphorus on reaction with NaOH gives PH<sub>3</sub> as one of the products. This is a:
  - (a) dimerization reaction
  - (b) disproportionation reaction
  - (c) condensation reaction
  - (d) precipitation reaction
  - [Hint:  $P_4^0 + 3NaOH + 3H_2O \rightarrow 3NaH_2PO_2 + PH_3$ ]

## BRAIN STORMING PROBLEMS

- Write down the two compounds of Vth or 15th group elements which are covalent in vapour state but ionic in solid state. [Ans.  $N_2O_5$ ,  $PCl_5$ ]
- Write the formula of:
  - (i) Scheele's green
- (iii) Graham salt
- (ii) Paris green
- (iv) Pearl white
- (i) CuHAsO3;
- (ii) (CH<sub>3</sub>COO)<sub>2</sub>Cu.3Cu(AsO<sub>2</sub>)<sub>2</sub>
- (iii) (NaPO<sub>3</sub>)<sub>6</sub>;
- (iv) BiOCl]
- Explain why all P—F bonds in PF<sub>5</sub> are not equivalent? [Ans. Phosphorus in PF<sub>5</sub> lie in  $sp^3d$  hybrid state, out of five P-F bonds, three are equatorial bonds which have different length.]
- 5. Write comment on non-existance of PI<sub>5</sub>?
- Although phosphorus pentabromide exists in the vapour phase as PBr<sub>5</sub> molecules, in the solid phase the substance is ionic and has the structure [PBr<sub>4</sub>] +Br. What is the expected geometry of PBr<sub>4</sub><sup>+</sup>?

[Ans. Tetrahedral]

7. With the help of NH<sub>3</sub>, O<sub>2</sub>, Pt and H<sub>2</sub>O, write equations for preparation of N<sub>2</sub>O from these substances.

[Hint: 
$$4NH_3(g) + 5O_2(g) \xrightarrow{Pt} 4NO(g) + 6H_2O(g)$$
  
 $2NO(g) + O_2(g) \longrightarrow 2NO_2(g)$   
 $3NO_2(g) + H_2O(l) \longrightarrow 2HNO_3(aq.) + NO(g)$   
 $HNO_3(g) + NH_3(aq.) \longrightarrow NH_4NO_3(aq.)$   
 $NH_4NO_3(aq.) \xrightarrow{\Delta} NH_4NO_3(s)$   
 $NH_4NO_3(s) \xrightarrow{\Delta} N_2O(g) + 2H_2O(g)$ ]

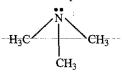

- 8. Give the formula of:
  - (i) Polyphosphoric acid
  - (ii) Polymetaphosphoric acid
  - (iii) Sodium triphosphate
  - (iv) Trimetaphosphate

Ans.

- (i)  $H_{n+2} P_n O_{3n+1}$ ;
- (ii)  $(HPO_3)_n$ ;
- (iii) Na<sub>5</sub>P<sub>3</sub>O<sub>10</sub> ;
- (iv) Na<sub>3</sub>P<sub>3</sub>O<sub>9</sub>]
- 9. Write down the formula of those compounds of phosphorus which are used as:
  - (i) detergent additive
- (ii) in soft drink
- (iii) in tooth powder
- (iv) animal feed additive

- [Ans.
- (i) Na<sub>5</sub>P<sub>3</sub>O<sub>10</sub>;
- (ii) H<sub>3</sub>PO<sub>4</sub>;
- (iii) CaHPO<sub>4</sub>·2H<sub>2</sub>O;
- (iv) CaHPO<sub>4</sub>·2H<sub>2</sub>O]
- 10. Comment on the structure of trimethyl amine [(CH<sub>3</sub>)<sub>3</sub>N] and trisilyl amine [(SiH<sub>3</sub>)<sub>3</sub>N].

[Hint: Trimethyl amine has pyramidal structure like NH3 because lone pair of electron is present at nitrogen.

Trisilyl amine has planar structure because lone pair of nitrogen is donated to vacant d-orbital of silicon.]

- 11. Explain why NF<sub>3</sub> has no donor property of electrons but PF<sub>3</sub> has, and PF3 forms several complexes.
- What is composition of Devarda's alloy? Which gas is evolved when this alloy is treated with HNO3? [Ans. Al 45%; Zn 5%; Cu 50%; NH<sub>3</sub>(g)]
- 13. When HNO<sub>3</sub> is added to conc. H<sub>2</sub>SO<sub>4</sub> we get NO<sub>2</sub><sup>+</sup> and  $NO_3^-$ ; explain this fact.

[Hint: 2HNO<sub>3</sub> 
$$\xrightarrow{\text{Conc. H}_2\text{SO}_4}$$
  $N_2\text{O}_5$  +  $H_2\text{O}_5$ 

In polar solvent, N<sub>2</sub>O<sub>5</sub> gives solvated ions NO<sub>2</sub><sup>+</sup> and NO<sub>3</sub><sup>-</sup>.]

14. Explain why nitride of lithium (Li<sub>3</sub>N) is more stable than nitride of potassium (K<sub>3</sub>N)?

[Hint: Lattice energy of Li<sub>3</sub>N is very high.]

15. In oxidation of  $P_4$  to  $P_4O_6$  we cannot use pure  $O_3$ ; we use mixture of O<sub>3</sub> and N<sub>2</sub>. What is the reason behind it?

[Hint: Pure O<sub>2</sub> will oxidise P<sub>4</sub>O<sub>6</sub> to P<sub>4</sub>O<sub>10</sub>.]

- 16. Arrange the following as indicated:
  - (a) As<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>3</sub>, N<sub>2</sub>O<sub>3</sub> (Decreasing acid strength)
  - (b) P<sub>2</sub>O<sub>5</sub>, N<sub>2</sub>O<sub>5</sub>, As<sub>2</sub>O<sub>3</sub>, Bi<sub>2</sub>O<sub>5</sub>, Sb<sub>2</sub>O<sub>5</sub>

(Decreasing acid strength)

- (c) N<sub>2</sub>O<sub>5</sub>, N<sub>2</sub>O<sub>5</sub>, N<sub>2</sub>O<sub>4</sub>, N<sub>2</sub>O<sub>3</sub>, NO (Increasing acid strength)
- (d) P<sub>2</sub>O<sub>5</sub>, Bi<sub>2</sub>O<sub>5</sub>, N<sub>2</sub>O<sub>5</sub>, Sb<sub>2</sub>O<sub>5</sub>, As<sub>2</sub>O<sub>3</sub> (Decreasing stability)
- (e) NBr<sub>3</sub>, NCl<sub>3</sub>, NF<sub>3</sub> (Decreasing stability)
- (f) NI<sub>3</sub>, NBr<sub>3</sub>, NCl<sub>3</sub>, NF<sub>3</sub> (Increasing Lewis base strength)
- (g) BiCl<sub>3</sub>, NCl<sub>3</sub>, PCl<sub>3</sub>, AsCl<sub>3</sub>, SbCl<sub>3</sub>

(Decreasing trend of hydrolysis)

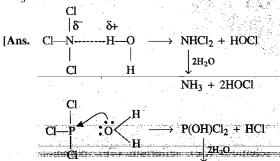

- (h) PF<sub>3</sub>, PCl<sub>3</sub>, PBr<sub>3</sub>, PI<sub>3</sub> (Decreasing Lewis acid strength)
- (i) H<sub>3</sub>SbO<sub>4</sub>, H<sub>3</sub>AsO<sub>4</sub>, H<sub>3</sub>PO<sub>4</sub>, HNO<sub>3</sub>

(Decreasing solubility in water)

[Ans. (a)  $N_2O_3 > P_2O_3 > As_2O_3$ 

(b)  $N_2O_5 > P_2O_5 > As_2O_5 > Sb_2O_5 > Bi_2O_5$ 

- (c)  $N_2O < NO < N_2O_3 < N_2O_4 < N_2O_5$
- (d)  $P_2O_5 > As_2O_3 > Sb_2O_5 > N_2O_5 > Bi_2O_5$
- (e)  $NF_3 > NCl_3 > NBr_3$
- (f)  $NF_3 < NCl_3 < NBr_3 < NI_3$
- (g)  $NCl_3 > PCl_3 > AsCl_3 > SbCl_3 > BiCl_3$
- (h)  $PF_3 > PCl_3 > PBr_3 > PI_3$
- (i)  $HNO_3 > H_3PO_4 > H_3AsO_4 > H_3SbO_4$ .]
- 17. What are the products formed by hydrolysis of NCl<sub>3</sub> and PCl<sub>3</sub>?

$$H_3PO_3 + 2HCl$$

- **18.** NF<sub>3</sub> is stable but NCl<sub>3</sub> and NI<sub>3</sub>, are unstable and explosive. Explain why?
  - **[Hint:** In NF<sub>3</sub>, there is strong  $p\pi$ - $p\pi$  bonding due to large electronegativity difference between N(3) and F(4). On the other hand, there, is weak  $p\pi$ - $p\pi$  bonding in NCl<sub>3</sub> and NI<sub>3</sub>, hence these compounds are unstable and explosive.]
- 19. Complete the following reactions:
  - (a)  $[Fe(CO)_5] + NO \longrightarrow$
  - (b)  $KNO_3 + KNO_2 + Cr_2O_3 \longrightarrow$
  - (c)  $Cr^{2+} + H^{+} + NO \longrightarrow$
  - (d)  $SO_2 + NO + H^+ \longrightarrow$
  - (e)  $MnO_4^- + NO + H^+ \longrightarrow$

- (f)  $SO_3^{2-} + NO_2^{-} + H^+ \longrightarrow$
- [Ans. (a)  $[Fe(CO)_5] + 2NO \xrightarrow{\Delta} [Fe(CO)_2(NO)_2] + 3CO$
- (b)  $3KNO_2 + KNO_3 + Cr_2O_3 \xrightarrow{\Delta} 2K_2CrO_4 + 4NO$
- (c)  $3Cr^{2+} + NO + 3H^{+} \longrightarrow NH_2OH + 3Cr^{3+}$
- (d)  $SO_2 + 2NO + H_2O \longrightarrow N_2O + H_2SO_4$
- (e)  $3MnO_4^- + 5NO + 4H^+ \longrightarrow 5NO_3^- + 3Mn^{2+} + 2H_2O$
- (f)  $SO_3^{2-} + 2NO_2^- + 2H^+ \longrightarrow SO_4^{2-} + 2NO_1^- + H_2O_1^-$
- 20. Answer the following questions:
  - (a) What is Swart's reagent?
  - (b) Give chemical formula of Vortex ring.
  - (c) Cold fire and Phossy Jaw are related to.....
  - (d) Which gas of nitrogen is used as anaesthetic in dental surgery?
  - (e) Give the chemical formula of phosphorus sulphide present in 'strike anywhere matches'.
  - (f) What is 'Ghost light'?
  - (g) What is the chemistry of Holme's signal?
  - [Ans. (a) SbF<sub>3</sub> is a fluorinating agent called Swart's reagent.
    - (b) White smokes of P<sub>2</sub>O<sub>5</sub> is called Vortex ring.
    - (c) White phosphorus.
    - (d) N<sub>2</sub>O
    - (e) P<sub>4</sub>S<sub>3</sub>
    - (f) Bones glow in dark due to oxidation of white phosphorus present. The phenomenon is called chemiluminescence.
    - (g) Mixture of CaC<sub>2</sub> and Ca<sub>3</sub>P<sub>2</sub> filled in container with a hole is thrown into sea or river, so that following reactions take place:

$$CaC_2 + 2H_2O \longrightarrow Ca(OH)_2 + C_2H_2$$

$$Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3 \text{ or } P_2H_4$$

P<sub>2</sub>H<sub>4</sub>, catches fire. The acetylene produces a bright luminous flame which serves as a signal to approaching ship or boat (Holme's signal).]

## INTEGER ANSWER Tupe Outstions

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. How many nitrogen oxides are known?
- 2. How many lone pairs are present in nitrogen molecule?
- 3. In group 15 elements, the number of unpaired electrons in valence shell is:
- 4. How many P—O—P bonds are present in P<sub>4</sub>O<sub>8</sub>?
- 5. When excess of ammonia and chlorine react, nitrogen and ammonium chloride are formed. Write the balanced equation and find out how many ammonium chloride molecules are involved in the balanced equation?
- 6. How many  $\sigma$ -bonds are present in  $N_2O_3$ ?
- 7. What is the basicity of pyrophosphoric acid?
- **8.** In solid PCl<sub>5</sub> molecule, how many P—Cl bonds are present in the cation?

### Answers

- 1. (5) Five oxides are known. These are  $N_2O$ , NO,  $N_2O_3$ , NO<sub>2</sub> and  $N_2O_5$ .
- 2. (2) Nitrogen molecule has a triple bond and each nitrogen atom is associated with a lone pair of electrons. :N == N:
- 3. (3) The valence shell in group 15 elements is  $ns^2np^3$  i.e., all the three p-orbitals are occupied by single electron each.
- 4. (6) The structure of  $P_4O_8$  is :  $O \leftarrow P \xrightarrow{O} O \xrightarrow{P} O P \rightarrow O$
- 5. (6)  $2NH_3 + 3Cl_2 \longrightarrow N_2 + 6HCl$   $6NH_3 + 6HCl \longrightarrow 6NH_4Cl$   $8NH_3 + 3Cl_2 \longrightarrow N_2 + 6NH_4Cl$
- **6.** (4) The structure of  $N_2O_3$  is  $O^1 = N^2 O^3 N^4 = O$
- 7. (4)  $H_4P_2O_7$ . It has four OH groups.
- 8. (4) [PCl<sub>4</sub>]<sup>+</sup>[PCl<sub>6</sub>]<sup>-</sup>

6	Bi (83)	Po (84)	At (85)
. 7	Uup (115)	Uuh (116)	

#### 11.1 POSITION IN PERIODIC TABLE

Group 16 or VIA of the extended form of periodic table consists of six elements—oxygen (O), sulphur (S), selenium (Se), tellurium (Te), polonium (Po) and ununhexium (Uuh)\*. This family is known as oxygen family. These (except polonium and ununhexium) are the ore forming elements and thus called **chalcogens.** These are *p*-block elements as the last differentiating electron is accommodated on *np* shell. These elements have six electrons in their valency shell and thus placed in the VIth group.

The elements oxygen and sulphur are common while selenium, tellurium and polonium are comparatively rare. Oxygen is the most abundant element and is found both in free as well as in combined state. Oxygen makes up 20.9% by volume and 23% by mass of atmosphere. Most of the oxygen present in the atmosphere is produced by photosynthesis in plants. It also occurs in the form of ozone in the upper atmosphere which protects us from the harmful radiations of the sun. Oxygen makes up 46.6% by mass of the earth's crust. Sulphur is the sixteenth most abundant element and constitutes 0.034% by mass of the earth's crust. It occurs mainly in combined form. The member, polonium is radioactive in nature. The inclusion of these elements in the same subgroup is justified on the basis of same electronic configuration and similarities as well as gradation in their physical and chemical properties.

Like other groups, the first element oxygen differs from other elements of the group in several respects.

#### 3 1. Electronic Configuration

The distribution of electrons in various energy shells of the atoms of these elements is given as below:

Element	At. No.	-	With inert gas core	
Oxygen	8	2, 6	$1s^2$ , $2s^2$ $2p^4$	[He] $2s^2 2p^4$
Sulphur	16	2, 8, 6	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^4$	[Ne] $3s^2 3p^4$
Selenium	34	2, 8, 18, 6	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^4$	[Ar] $3d^{10}$ , $4s^2 4p^4$
Tellurium	52	2, 8, 18, 18, 6	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ , $5s^2$ $5p^4$	[Kr] $4d^{10}$ , $5s^2$ $5p^4$
Polonium	84	2, 8, 18, 32, 18, 6	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ $4f^{14}$ , $5s^2$ $5p^6$ $5d^{10}$ , $6s^2$ $6p^4$	[Xe] $4f^{14}$ , $5d^{10}$ , $6s^2$ $6p^4$
Ununhexium	116	2, 8, 18, 32, 32, 18, 6	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ $4f^{14}$ , $5s^2$ $5p^6$ $5d^{10}$ $5f^{14}$ ,	[Rn] $5f^{14}$ , $6d^{10}$ , $7s^2$ $7p^4$
		. `	$6s^2 6p^6 6d^{10}, 7s^2 7p^4$	

<sup>\*</sup>Recently a new element with atomic number 116 (Ununhexium) has been discovered. It is a synthetic and radioactive element. It is not very stable element. Not much is known about its properties.

All have six electrons in their outermost shell, *i.e.*, they have electronic structure  $s^2p^4$ . The penultimate shell contains 2 electrons in oxygen, 8 electrons in sulphur and 18 electrons in Se, Te, Po and Uuh. This explains why oxygen differs from sulphur and these two from the remaining elements.

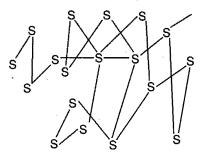

#### 2. Physical Characteristics

(a) Physical state: Oxygen is a gas while others are solids. Oxygen molecule is diatomic while the molecules of other elements are more complex. Sulphur, selenium and tellurium exist as staggered 8-atom rings. However, the tendency to exist in 8-atom rings is maximum with sulphur and decreases as we go down the group. In  $S_8$  molecule, every sulphur atom is in  $sp^3$  hybridized state involving both bonding and non-bonding pairs of electrons.

Fig. 11.1 Staggered ring structure of sulphur molecule, S<sub>8</sub>

[Oxygen atom has the tendency to form multiple bonds ( $p\pi$ — $p\pi$  interaction) with other oxygen atom on account of small size while this tendency is missing in sulphur atom. The bond energy of oxygen-oxygen double bond (O=O) is quite large (about three times that of oxygen-oxygen single bond, O—O = 34.9 kcal mol<sup>-1</sup>) while sulphur-sulphur double bond (S=S) is not so large (less than double of sulphur-sulphur single bond, S—S = 63.8 kcal mol<sup>-1</sup>). As a result, —O—O—O— chains are less stable as compared to O=O molecule while —S—S—S— chains are more stable than S=S molecule. Therefore, at room temperature, while oxygen exists as a diatomic gas molecule, sulphur exists as S<sub>8</sub> solid.]

The plastic sulphur which is formed by pouring liquid sulphur into water contains zig-zag long chains of sulphur atoms.

At temperatures above the boiling points, sulphur forms a red vapour, which turns to yellow as temperature is increased. In vapour there exist  $S_8$ ,  $S_6$  and  $S_2$  molecules. Above 1000°C, there exist only  $S_2$  molecule, which has structure like  $O_2$ .

(b) Metallic and non-metallic character: Metallic character increases with the increase of atomic number. Oxygen

and sulphur are distinctly non-metallic. Selenium and tellurium show both non-metallic and metallic characters but polonium is definitely a metal.

- (c) There is a gradual gradation in physical properties:
- (i) Atomic and ionic radii: The atomic radii of the elements of group 16 are smaller than those of the corresponding elements of group 15. The atomic radii of the elements of this group increase gradually on moving down the group.

The smaller atomic radii of group 16 elements as compared with corresponding elements of groups 15 are due to the increased effective nuclear charge with increase in greater attraction towards nucleus. The attraction brings contraction in size. The gradual increase on moving down the group is due to the increase in the number of electron shells from member to member.

In the formation of anions, two electrons are being added to an atom. Therefore, the effective nuclear charge is reduced and hence, the electron closed expands. Thus, the negative ions  $(M^2)$  are bigger in size than the corresponding atoms. Like atomic radii, ionic radii also increase gradually on moving down the group.

(ii) Ionisation energy: The ionisation enthalpies are high and thus the elements do not lose the electrons to form positive ions easily. The values decrease as the atomic number increases from O to Po and thus the tendency to form positive ion increases gradually, *i.e.*, metallic nature increases.

	О	S	Se	Te	Po
Ionisation energy $\Delta_i H_1$ (kJ mol <sup>-1</sup> )	1314	1000	941	869	813
,	3388	2251	2045	1790	· –

The ionisation energies of first three elements of group 16 are less than corresponding elements of group 15 inspite of the fact that nuclear charge increases. The abnormal behaviour is due to symmetrical and more stable electronic configuration of N, P and As as compared to O, S and Se respectively.

Decreases gradually

However, the second ionisation values of group 16 elements are higher than those of group 15.

(iii) Electronegativity: Electronegativity decreases gradually. Oxygen is second most electronegative element after fluorine.

This decrease indicates a change from non-metallic to metallic character.

(iv) Melting and boiling points: The melting and boiling points increase gradually with increase in atomic number.

O S Se Te

Melting point (°C) -219 119 217 450

(Monoclinic)

Boiling point (°C) -183 445 688 990

(v) Electron affinity: Group 16 elements have high electron affinities. On moving from oxygen to sulphur, the  $EA_1$  value increases and then decreases from S to Po:

Element O S Se Te Po  $EA_1 (kJ mol^{-1})$  -141 -200 -195 -190 -183

The electron density in 2p energy shell in oxygen is high due to small size of oxygen atom and thus, there is some resistance to the incoming electron and thereby the  $EA_1$  of oxygen is comparatively low. Sulphur has maximum value and on moving from S to Po, the  $EA_1$  values decrease due to increased size.

(d) Allotropy: All the elements show allotropy:

 Element
 Allotropic forms

 Oxygen
 Ordinary oxygen and ozone

 Sulphur
 Rhombic, monoclinic, plastic, amorphous

 Selenium
 Red form (non-metallic), grey form (metallic form)

 Tellurium
 Crystalline and amorphous

 Polonium
 α and β forms (Both are metallic forms)

(e) Catenation: Oxygen and sulphur show the property of catenation. The property is more pronounced in sulphur. H—O—O—H, H—S—S—H, H—S—S—H, H—S—S—H, H—S—S—H, the peroxides and polysulphides are fairly stable.

Note: Catenated compounds of sulphur are the following:

- (i) Polysulphides:  $S_n^{2-}$  where n = 2, 3, 4, etc.
- (ii) Sulphanes: X—S<sub>n</sub>—X, where X = I, Cl, CN, etc. Compounds corresponding to n ~ 100 have been reported.
- (iii) Polysulphonic acids: These have general formula HO<sub>3</sub>S—S<sub>n</sub>—SO<sub>3</sub>H compounds corresponding to n ~ 22 have been reported. These are also called thionic acids.
- (f) Oxidation states: As the configuration of outermost shell is  $ns^2$   $np^4$ , these elements try to gain or share two electrons in order to attain inert gas configuration. Oxygen being highly electronegative shows -2 oxidation state in its compounds except in oxygen fluorides and most of the metal oxides are ionic and contain oxygen as dinegative anion,  $O^{2-}$ . Since, the electronegativity decreases, the tendency to exhibit -2 oxidation state decreases as we go down in the group. However, positive oxidation states are exhibited by S, Se, Te and Po. In addition to +2 oxidation state, +4 and +6 oxidation states are observed. This is due to the availability of d-orbitals in these elements. Oxygen has no d-orbitals and hence cannot show +4 and +6 oxidation states while sulphur can have 2, 4 or 6 unpaired orbitals forming 2, 4 or 6 covalent bonds.

S-atom	3 <i>s</i>	3 <i>p</i>		
(Ground state)	$\uparrow\downarrow$	$\uparrow\downarrow\uparrow\uparrow$		+2
S-atom (Excited state)	$\uparrow\downarrow$	$\uparrow \uparrow \uparrow \uparrow$	$\uparrow$	+4
S-atom (Doubly excited state)	$\uparrow$	$\boxed{\uparrow   \uparrow   \uparrow}$	$\uparrow$	+6

Thus, oxygen is never more than divalent while other members may be divalent, tetravalent and hexavalent. The compounds having +4 oxidation state show both oxidising and reducing properties while compounds having +6 oxidation states are only oxidising.

(g) Multiple bonding: Oxygen atom has the tendency to form multiple bonds ( $p\pi$ – $p\pi$  interaction) with the other oxygen atom on account of small size and high electronegativity. However, the rest of the elements do not form  $p\pi$ – $p\pi$  multiple bonds due to their large size. Sulphur and higher members of group 16 possess vacant d-orbitals in their valence shell. They use these orbitals to form  $d\pi$ – $p\pi$  bonds. However, this tendency is maximum and stronger in sulphur and decreases from sulphur onwards.

#### 3. Trends in Chemical Reactivity

Oxygen is the most reactive element of the group despite it has high bond dissociation energy of oxygen molecule (493.4 kJ mol<sup>-1</sup>) as nearly all its reactions are exothermic. Once initiated, these reactions continue spontaneously. Oxygen directly combines with almost all the metals except noble metals, all the non-metals except noble gases and halogens and many compounds under suitable conditions. The oxides are generally stable compounds. The elements such as W, Pt, Au, halogens and noble gases which do not directly combine with oxygen, form compounds with oxygen indirectly.

After oxygen, sulphur is quite reactive element especially at high temperatures which help in breaking of S—S bonds. Sulphur burns in air and reacts directly with carbon, phosphorus, arsenic and many metals. Oxidising acids oxidise it into  $SO_2$  and alkalies dissolve it to give sulphides and thiosulphates. It reacts with  $H_2$  and halogens. The sulphides are stable compounds and many metals are found in nature in the form of sulphides.

However, the reactivity of group 16 elements decreases from oxygen to polonium.

Selenium and tellurium combine with highly electropositive elements such as alkali and alkaline earth metals. Se and Te combine with oxygen, fluorine and chlorine. In general, the compounds of selenium and tellurium are less stable than oxygen and sulphur.

Some important trends in chemical reactivity of elements of group 16 are discussed here.

#### (a) Hydrides

All the elements of this group form the hydrides of type  $H_2M$  where, M = O, S, Se, Te and Po, *i.e.*,

 $H_2O$  is obtained by burning hydrogen in the atmosphere of oxygen while  $H_2S$ ,  $H_2Se$  and  $H_2Te$  are obtained by the action of acids on sulphides, selenides and tellurides.

FeS + 
$$H_2SO_4 \longrightarrow FeSO_4 + H_2S$$
  
Na<sub>2</sub>Se +  $H_2SO_4 \longrightarrow Na_2SO_4 + H_2Se$ 

(i) Physical state: Water is colourless, odourless liquid while other hydrides are colourless, poisonous gases with bad odours.

- (ii) Volatility: Water has low volatility (high boiling point) as hydrogen bonding brings association.  $H_2S$  has high volatility as no hydrogen bonding is present. Volatility decreases from  $H_2S$  to  $H_2$ Te due to increase in molecular masses of the hydrides.
- (iii) Covalent character: As the electronegativity difference between M and H decreases, the covalent character of these hydrides increases from  $H_2O$  to  $H_2Te$ . Water molecule is highly polar. It has high dielectric constant and hence acts as an excellent solvent for inorganic compounds.
- (iv) Thermal stability: The thermal stability decreases as the atomic mass increases. Water dissociates at  $2000^{\circ}$ C while tellurium hydride,  $H_2$ Te, decomposes at room temperature. This is due to an increase in M—H bond length.
- (v) Acidic nature: The hydrides are all weak acids and dissociate to varying degrees to give  $H^+$  ions. The acidic strength increases from  $H_2O$  to  $H_2Te$  as it is evident from the values of dissociation constants.

$$H_2O$$
  $H_2S$   $H_2Se$   $H_2Te$  Dissociation  $1.0 \times 10^{-14}$   $1.0 \times 10^{-7}$   $1.7 \times 10^{-4}$   $2.3 \times 10^{-3}$  constant (25°C)

The increasing trend can be explained on the basis of dissociation energies. The dissociation energies decrease as the bond length M—H increases from oxygen to tellurium. This facilitates the release of proton. The acidic nature can also be explained on the basis of charge density on  $M^{2-}$  anion. The charge density on the  $M^{2-}$  ion decreases as the size of M-atom increases from oxygen to tellurium. The decrease in charge density is responsible for the decrease in dissociation energies and thereby increasing the tendency to furnish proton.

- (vi) Reducing nature: All hydrides except  $H_2O$  act as reducing agents. The reducing nature increases as the atomic number of the central atom increases. This is due to weakening of M—H bond as the bond length increases with increase of size of M-atom.
- (vii) Burning:  $H_2S$ ,  $H_2Se$ ,  $H_2Te$  and  $H_2Po$  burn in atmosphere of oxygen with blue flame forming dioxides.

$$2H_2S + 3O_2 \longrightarrow 2H_2O + 2SO_2$$

(viii) Shape: All these hydrides are V-shaped. In these hydrides, the central atom is  $sp^3$ -hybridized. The bond angles are 104.5°, 92.5°, 91° and 90° in  $H_2O$ ,  $H_2S$ ,  $H_2Se$  and  $H_2Te$ , respectively.

This can be explained on the basis of decreasing electronegativity of central atom and decreasing tendency of  $sp^3$ -hybridization.

#### Other hydrides

Oxygen and sulphur have a tendency to form polyoxides and polysulphides which are comparatively less stable. The two common examples are  $H_2O_2$  (hydrogen peroxide) and  $H_2S_2$  (hydrogen disulphide). They decompose on heating.

$$2H_2O_2 \longrightarrow 2H_2O + O_2$$

$$H_2S_2 \longrightarrow H_2S + S$$

Hydrogen polysulphides (H— $S_n$ —H', n may be 2, 3, 4, 5) are yellow oily liquids which possess a more strong odour than  $H_2S$ .

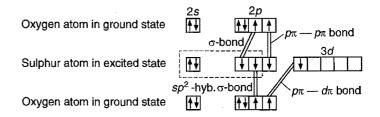

#### (b) Oxides

The most important oxides are of the type  $MO_2$  and  $MO_3$ .  $SO_2$  and  $SeO_2$  are acidic oxides and are soluble in water.  $TeO_2$  and  $PoO_2$  are insoluble in water. These are amphoteric oxides as they dissolve in both acids and bases.

$$SO_2 + H_2O \longrightarrow H_2SO_3$$
 (Sulphurous acid)  
 $SeO_2 + H_2O \longrightarrow H_2SeO_3$  (Selenous acid)  
 $TeO_2 + 2NaOH \longrightarrow Na_2TeO_3 + H_2O$   
 $Sodium \ tellurite$   
 $2TeO_2 + HNO_3 \longrightarrow 2TeO_2 \cdot HNO_3 \ or \ Te_2O_3 \cdot (OH)NO_3$   
Basic nitrate

 $SO_2$  is a gas,  $SeO_2$  is a volatile solid and  $TeO_2$  is a white non-volatile solid. All the dioxides possess different structures.  $SO_2$  is an angular molecule with an O—S—O angle of 119.5°. The sulphur undergoes  $sp^2$ -hybridization. Both the bonds have same bond lengths. This suggests resonance in the molecule.

 $SeO_2$  has the same structure as  $SO_2$  in the gaseous state but the solid has a chain like structure which is not planar.

$$O_{p\pi} = \frac{\sigma}{p\pi} S_{p\pi} = \frac{\sigma}{d\pi} O \longrightarrow O_{p\pi} = \frac{\sigma}{d\pi} S_{p\pi} = \frac{\sigma}{d\pi} O \longrightarrow O_{p\pi} = \frac{\sigma}{d\pi} S_{p\pi} = \frac{\sigma}{d\pi} O$$

Fig. 11.2 Formation of SO<sub>2</sub> molecule

TeO<sub>2</sub> and PoO<sub>2</sub> are crystalline ionic solids.

**Trioxides:** SO<sub>3</sub>, SeO<sub>3</sub> and TeO<sub>3</sub> are acidic in nature.

$$SO_3 + H_2O \longrightarrow H_2SO_4$$
 (Sulphuric acid)  
 $SeO_3 + H_2O \longrightarrow H_2SeO_4$  (Selenic acid)  
 $TeO_3 + 3H_2O \longrightarrow H_6TeO_6$  (Telluric acid)

The acidic nature decreases on moving down the group.  $SO_3$  is a gas and has plane triangular structure. The structure of  $SO_3$  is similar to that of  $SO_2$  except for the fact that lone pair of electrons of sulphur atom is donated to third oxygen atom. According to another view, the true structure of  $SO_3$  molecule is considered to be resonance hybrid of the following structures.

$$0 \longrightarrow 0 \longrightarrow 0 \longrightarrow 0 \longrightarrow 0$$

$$0 \longrightarrow 0 \longrightarrow 0 \longrightarrow 0$$

$$0 \longrightarrow 0 \longrightarrow 0$$

$$0 \longrightarrow 0 \longrightarrow 0$$

In the solid state, SO<sub>3</sub> exists as a cyclic trimer or a linear chain.

Cyclic trimer of SO<sub>3</sub>

Linear chain of SO<sub>3</sub>

Solid selenium trioxide is a cyclictetramer [Se<sub>4</sub>O<sub>12</sub>].

#### (c) Oxyacids or oxoacids

Sulphur forms a number of oxyacids but selenium and tellurium form only two series of oxyacids, the -ous and -ic acids.

$H_2SO_3$	$H_2SeO_3$	$H_2TeO_3$
Sulphurous acid	Selenous acid	Tellurous acid
Salts: Sulphite	Selenites	Tellurites
$H_2SO_4$	$H_2SeO_4$	H <sub>2</sub> TeO <sub>4</sub> or H <sub>6</sub> TeO <sub>6</sub>
Sulphuric acid	Selenic acid	Telluric acid
Sulphates	Selenates	Tellurates

Oxyacids with S—S linkages are called thioacids and with O—O linkages are termed peroxy acids. Thionic acids have two—SO<sub>3</sub>H groups linked either directly or through a S—chain (polythionic acids).

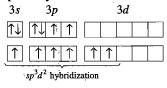

With increase oxidation number, the acid strength of oxyacid of an element increases, *i.e.*, sulphuric acid is stronger than sulphurous acid. In the oxyacids of group 16 elements in same oxidation state, the acidic nature decreases from S to Te. The -ous acids act as reducing agents while -ic acids act as oxidising

agents. These properties decrease from S to Te. Oxyacids are dibasic in nature.

#### (d) Halides

S, Se and Te form hexafluorides showing the maximum valency of six. They all involve  $sp^3d^2$  hybridization.

Sulphur atom in ground state
Sulphur atom in excited state

Thus, hexafluorides possess octahedral structure.

These are colourless gases. SF<sub>6</sub> is extremely inert.

Se $F_6$  is slightly reactive while Te $F_6$  is hydrolysed by water.

 $\text{TeF}_6 + 6\text{H}_2\text{O} \rightarrow 6\text{HF} + \text{H}_6\text{TeO}_6$ 

No other halogen forms the hexahalides due to larger size of Cl, Br and I.

Many tetrahalides are known. SF<sub>4</sub> is a gas, SeF<sub>4</sub> is a liquid while TeF<sub>4</sub> is a solid. S, Se, Te

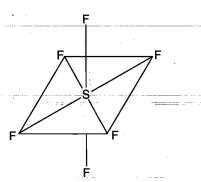

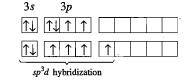

Fig. 11.3

and Po form tetrachlorides and bromides while Te and Po form tetraiodides. All tetrahalides possess trigonal bipyramid structure with  $sp^3d$  hybridization.

Sulphur atom in ground state Sulphur atom in excited state

Four unpaired electrons form bonds with four halogen atoms and one position is occupied by lone pair.

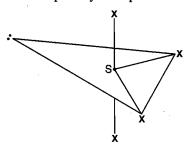

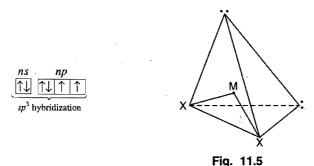

Fig. 11.4

 $SF_4$  is very reactive and is readily hydrolysed by water to give  $SO_2$  and HF inspite of the fact that average bond energy in  $SF_4$  is greater than  $SF_6$ . This is due to the presence of empty 3d-orbitals in sulphur atom in  $SF_4$ . It is used as fluorinating agent for many inorganic and organic compounds.

All the elements except selenium form stable dichlorides and dibromides. Di-iodides are not formed. Dihalides form tetrahedral molecules due to  $sp^3$  hybridization.

The bond angle is less than 109°28' due to the presence of lone pairs. The bond angle is 103° in SCl<sub>2</sub>, 101.5° in OF<sub>2</sub> and 98° in TeBr<sub>2</sub>.

Dimeric monohalides as  $S_2F_2$ ,  $S_2Cl_2$  and  $S_2Br_2$  are known. Their structure is similar to  $H_2O_2$ .

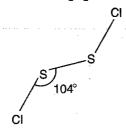

Fig. 11.6

[Note: As fluorine is more electronegative than oxygen, the compounds of oxygen and fluorine are called fluorides. For example, OF<sub>2</sub> is named oxygen difluoride. The compounds of oxygen and other halogens are called oxides as oxygen is more electronegative than chlorine, bromine and iodine. For example, ClO<sub>2</sub> is called chlorine dioxide and I<sub>2</sub>O<sub>5</sub> is named iodine pentoxide.]

#### (e) Oxyhalides

Only S and Se form oxyhalides. They are called thionyl and selenyl halides.

SOF <sub>2</sub>	· SOCl <sub>2</sub>	SOBr <sub>2</sub>
SeOF <sub>2</sub>	SeOCl <sub>2</sub>	SeOBr <sub>2</sub>

These react with water readily.

$$SOCl_2 + H_2O \longrightarrow SO_2 + 2HCl$$

In addition, sulphuryl halides are also known.

$$SO_2X_2$$

These may be regarded as derivatives of H<sub>2</sub>SO<sub>4</sub> where both the —OH groups have been replaced by two halogens atoms.

#### 11.2 ABNORMAL BEHAVIOUR OF OXYGEN

Oxygen differs from rest of the members of VIA group elements. The abnormal behaviour is attributed due to the following inherent characteristics:

- (i) Small size
- (ii) High electronegativity
- (iii) Non-availability of d-orbitals in the valency shell.

#### Points of difference

- (i) Oxygen is a gas while others are solids.
- (ii) It is diatomic molecule, while the rest are complex molecules, e.g.,  $S_8$ ,  $S_{e_8}$  with puckered ring structure.
- (iii) Oxygen is highly non-metallic due to high value of electronegativity.
- (iv) Oxygen is more ionic in its compounds. The dinegative anion  ${\rm O}^{2-}$  is quite common. The dinegative anions of other members are less common.
- (v) Oxygen exhibits an oxidation state of only -2 except in OF<sub>2</sub> and peroxides. It does not show +4 and +6 oxidation states as shown by other members.
- (vi) Oxygen molecule is highly stable. The two atoms are held together by multiple bonds. The bonds are fairly strong and bond energy is quite high (117 kcal per mole). It is only at a high temperature that these bonds are broken and oxygen atoms react with other materials. Thus, ordinary oxygen is not active under ordinary conditions.
- (vii) Hydrogen bonding is present in water and many other compounds due to high electronegativity of oxygen. On account of this, water boils at higher temperature.
- (viii) Oxygen molecule is paramagnetic in nature in gaseous, liquid and solid states. It is weakly attracted by a magnet. It has been explained by molecular orbital theory that oxygen molecule has two unpaired electrons.
  - (ix) Oxygen is the most abundant element in the earth's crust.
- (x) Metals like Cu, Ag, Hg, etc., show lesser affinity with O<sub>2</sub> to form oxide than with sulphur to form sulphide. It is due to polarizing power of Cu<sup>2+</sup>, Ag<sup>+</sup>, Hg<sup>2+</sup> ion, owing to which they form strong bond with S<sup>2-</sup>.

#### 11.4 OXYGEN

**Historical:** Priestley and Schoole obtained oxygen within a few months of each other by heating suitable oxygen compounds. Schoole called it vital air or fire air. Lavoisier regarded it as an essential constituent of all acids and named it oxygen (oxus = acid, gennas = maker).

**Occurrence:** Oxygen occurs in the atmosphere to the extent of about 21% by volume (23% by mass). This percentage remains constant by the operation of the highly complex process termed **photosynthesis**. It is an essential ingredient in all living matter and is of great importance in respiration and combustion. It is most abundant element and forms about one half of the earth's crust. It forms a large part of nearly all the rocks and is present to the extent of 89% by weight in water.

#### **M** Preparation

Oxygen can be obtained in the laboratory by following methods:

(i) From oxides: (a) By thermal decomposition of the oxides of metals which are in lower part of electrochemical series.

$$2\text{HgO} \xrightarrow{450^{\circ}\text{C}} 2\text{Hg} + \text{O}_2; \quad 2\text{Ag}_2\text{O} \xrightarrow{350^{\circ}\text{C}} 4\text{Ag} + \text{O}_2$$

(b) By the thermal decomposition of higher oxides.

$$3MnO_2 \xrightarrow{\text{Heat}} Mn_3O_4 + O_2; \ 2Pb_3O_4 \xrightarrow{\text{Heat}} 6PbO + O_2$$

$$2BaO_2 \xrightarrow{\text{Heat}} 2BaO + O_2$$

- (c) By action of conc. H<sub>2</sub>SO<sub>4</sub> on MnO<sub>2</sub>.
  - $2MnO_2 + 2H_2SO_4 \longrightarrow 2MnSO_4 + 2H_2O + O_2$
- (d) By action of water on sodium peroxide (oxone).

$$2Na_2O_2 + 2H_2O \longrightarrow 4NaOH + O_2$$

(ii) From salts: (a) Alkali nitrates on heating evolve oxygen.

$$2NaNO_3 \longrightarrow 2NaNO_2 + O_2$$
;  $2KNO_3 \longrightarrow 2KNO_2 + O_2$ 

(b) K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, KMnO<sub>4</sub> and KClO<sub>3</sub> decompose at high temperatures evolving oxygen.

$$4K_{2}Cr_{2}O_{7} \xrightarrow{400^{\circ}C} 4K_{2}CrO_{4} + 2Cr_{2}O_{3} + 3O_{2}$$

$$2KMnO_{4} \xrightarrow{250^{\circ}C} K_{2}MnO_{4} + MnO_{2} + O_{2}$$

$$2KClO_{3} \xrightarrow{400^{\circ}C} 2KCl + 3O_{2}$$

(c) By heating KMnO<sub>4</sub> or  $K_2Cr_2O_7$  with concentrated  $H_2SO_4$ .  $4KMnO_4 + 6H_2SO_4 \rightarrow 2K_2SO_4 + 4MnSO_4 + 6H_2O + 5O_2$  $2K_2Cr_2O_7 + 8H_2SO_4 \rightarrow 2K_2SO_4 + 2Cr_2(SO_4)_3 + 8H_2O + 3O_2$ 

(d) By adding H<sub>2</sub>O<sub>2</sub> to acidified KMnO<sub>4</sub> solution.

$$2KMnO_4 + 3H_2SO_4(dil.) \rightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$

$$\frac{[H_2O_2 + O \rightarrow H_2O + O_2] \times 5}{2KMnO_4 + 3H_2SO_4 + 5H_2O_2 \rightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 5O_2}$$

Pure oxygen is obtained by this reaction.

Laboratory preparation: The usual laboratory method consists in heating of a mixture of potassium chlorate and manganese dioxide in ratio of 4:1. KClO<sub>3</sub> evolves oxygen at 375°C. At this temperature, it melts and converted into potassium perchlorate which decomposes at higher temperature to evolve oxygen. When MnO<sub>2</sub> is added, it starts giving oxygen at 250°C. Here MnO<sub>2</sub> acts as a catalyst.

 $MnO_2$  used for this purpose should be completely free from carbon as  $KClO_3$  and carbon mixture is explosive in nature. The mixture should be first heated gently and then strongly when it is ensured that there is no vigorous reaction.

#### Properties

Oxygen is a colourless, odourless and tasteless gas. It is little heavier than air and is slightly soluble in water. This small amount of dissolved oxygen in water supports the respiration of fish and other aquatic animals. It is soluble in alkaline pyrogallol. It can be liquefied to a pale blue liquid (b.pt.–183°C) by compressing the gas at a very low temperature. It is transformed into a blue solid on further cooling (freezing point = -218.4°C). Although  $O_2$  has an even number of electrons, two of them are unpaired, making the molecule **paramagnetic**; since it behaves like a tiny magnet and is attracted to a magnetic field. It exhibits allotropy. Its allotropic modification is ozone  $(O_3)$ . There are three isotopes of oxygen with mass numbers 16, 17 and 18 ( $O^{16}$ ,  $O^{17}$  and  $O^{18}$ ).  $O^{16}$  is the main one with an abundance of nearly 99.8%. The others are  $O^{17}$  (0.04%) and  $O^{18}$  (0.2%).

Oxygen is not a combustible gas, but it is a strong supporter of combustion. It is very active element. It directly combines with almost all metals (except noble metals) and non-metals (except zero group elements and halogens) and reacts with many compounds under suitable conditions. In fact, all the chemical reactions of oxygen are oxidation reactions. Except very few, the reactions with oxygen are exothermic in nature. A flame may also be produced in certain cases.

#### **■** Reactions with metals

(a) Active metals react at room temperature forming respective oxides.

$$4Na + O_2 \longrightarrow 2Na_2O$$
  
 $2Ca + O_2 \longrightarrow 2CaO$ 

However, Na, K, Rb, etc., further combine with oxygen to form peroxides and superoxides.

of in peroxides and superoxides.
$$M \xrightarrow{O_2} M_2O \xrightarrow{O_2} M_2O_2 \xrightarrow{O_2} MO_2$$
Normal oxide Peroxide Super oxide
$$(Li_2O) \qquad (Na_2O_2) \qquad (KO_2, RbO_2, CsO_2)$$

(b) Magnesium burns in atmosphere of  $O_2$  to form magnesium oxide.

$$2Mg + O_2 \longrightarrow 2MgO$$

(c) Metals like Fe, Al combine with dioxygen on heating.

$$4Al + 3O_2 \longrightarrow 2Al_2O_3$$
  
 $4Fe + 3O_2 \longrightarrow 2Fe_2O_3$ 

#### **■** Reactions with nonmetals

Most of the nonmetals react with oxygen under high temperatures and form respective oxides. For example,

$$\begin{array}{c} \text{Hydrogen}: \ 2\text{H}_2 + \text{O}_2 & \xrightarrow{\text{or-electric} \\ \text{discharge}} & \text{Water} \\ \\ \text{Nitrogen}: \quad \text{N}_2 + \text{O}_2 & \xrightarrow{\text{3273 K}} & \text{2NO} \\ \text{Nitric oxide} \\ \\ \text{Sulphur}: \quad -\text{S} + \text{O}_2 & \xrightarrow{\text{Heat}} & \text{SO}_2 \\ \text{Sulphur dioxide} \\ \\ \text{Carbon}: \ 2\text{C} + \text{O}_2 & \xrightarrow{\text{Heat}} & \text{2CO} \\ \text{Carbon monoxide} \\ \\ \text{C} + \text{O}_2 & \xrightarrow{\text{Heat}} & \text{CO}_2 \\ \text{(Excess)} & \text{Carbondioxide} \\ \\ \text{Phosphorus}: \ \text{P}_4 + 5\text{O}_2 & \xrightarrow{\text{Heat}} & \text{P}_4\text{O}_{10} \\ \text{Phosphorus pentoxide} \\ \end{array}$$

#### **Reactions with compounds**

Oxygen is an oxidising agent. It oxidises many compounds under specific conditions. Some examples are given here.

$$2NO + O_2 \longrightarrow 2NO_2$$

$$4HCl + O_2 \xrightarrow{700 \text{ K}} 2H_2O + Cl_2 \quad \text{(Deacon's process)}$$

$$4NH_3 + 5O_2 \xrightarrow{1073 \text{ K}} 4NO + 6H_2O \quad \text{(Ostwald's process)}$$

$$2SO_2 + O_2 \xrightarrow{723 \text{ K}} 2SO_3 \quad \text{(Contact process)}$$

$$2ZnS + 3O_2 \longrightarrow 2ZnO + 2SO_2$$

$$C_xH_y + \left(x + \frac{y}{4}\right)O_2 \longrightarrow XCO_2 + \frac{y}{2}H_2O$$

#### Structure

The diatomic oxygen molecule has an unusual electronic structure. It is believed that two oxygen atoms in the molecule are bonded by a covalent double bond.

$$\ddot{\circ}$$
: $\ddot{\circ}$ : $\ddot{\circ}$ : $\ddot{\circ}$ : $\ddot{\circ}$ = $\ddot{\circ}$ :

However, the above structure is not supported by its paramagnetic nature. It has been suggested that between the two oxygen atoms only one covalent bond is established leaving two unpaired electrons, one in each atom.

This structure although can explain paramagnetic behaviour yet it does not explain high dissociation energy of oxygen molecule and does not conform to the octet rule.

Another structure, involving 3-electron bonds, has been suggested by **Pauling.** Two oxygen atoms are joined by one 2-electron bond and two 3-electron bonds. The structure accounts for two unpaired electrons and for the high dissociation energy but is contrary to octet rule.

$$:0$$
: $:0$ :

A better explanation for the existence of two unpaired electrons (paramagnetic behaviour) and a very high dissociation energy of  $O_2$  molecule has been provided by molecular orbital theory according to which the structure of  $O_2$  molecule is given below:

$$KK\sigma(2s)^2\sigma^*(2s)^2\sigma(2p_x)^2\pi(2p_y)^2\pi(2p_z)^2\pi^*(2p_y)^1\pi^*(2p_z)^1$$
  
Bond order in this case is  $\frac{1}{2}(8-4)=2$ 

#### **⊠** Uses

- (i) Oxygen mixed with helium or carbon dioxide is used for artificial respiration.
- (ii) Liquid oxygen is an important constituent of fuels used in rockets.
- (iii) Liquid oxygen mixed with finely divided carbon acts like a dynamite in coal mining.
- (iv) Oxygen is used for production of oxy-hydrogen or oxy-acetylene flames which are employed for cutting and welding purposes.
  - (v) Oxygen is used as an oxidising agent in several reactions.
- (vi) Oxygen is used in the manufacture of large number of compounds such as phenol, ethylene oxide, sulphur dioxide, sulphuric acid, nitric acid, chlorine, etc.
- (vii) <sup>18</sup>O is used as a tracer in the study of tracer mechanisms.

## 11.5 OXIDES

Oxygen combines nearly with all other elements except inert gases, noble metals and halogens. The binary compounds of oxygen with other elements are called oxides. However, the compounds of oxygen and fluorine (OF<sub>2</sub>, O<sub>2</sub>F<sub>2</sub>) are not called as oxides but oxygen fluorides as fluorine is more electronegative than oxygen.

Oxides may be prepared by the following general methods:

1. By burning of elements such as C, P, S, Na, K, Mg, etc., in air or oxygen atmosphere.

$$C + O_2 \longrightarrow CO_2$$
 (Carbon burns with flush light)  
 $S + O_2 \longrightarrow SO_2$  (Sulphur burns with blue light)  
 $4Na + O_2 \longrightarrow 2Na_2O$  (Sodium burns with yellow light)

$$4K + O_2 \longrightarrow 2K_2O$$
 (Potassium burns with violet light)  $2Mg + O_2 \longrightarrow 2MgO$  (Magnesium burns with white light)

2. By strongly heating carbonates, hydroxides or nitrates.

$$Cu(OH)_2 \longrightarrow CuO + H_2O$$

$$CaCO_3 \longrightarrow CaO + CO_2$$

$$2Pb(NO_3)_2 \longrightarrow 2PbO + 4NO_2 + O_2$$

$$2Al(OH)_3 \longrightarrow Al_2O_3 + 3H_2O$$

$$CuCO_3 \longrightarrow CuO + CO_2$$

$$2Ba(NO_3)_2 \longrightarrow 2BaO + 4NO_2 + O_2$$

(The carbonates, hydroxides of alkali metals do not decompose on heating and nitrates of alkali metals form nitrites on heating.)

3. The oxides of some of the non-metals and weak metals can be formed by the oxidation of the element with nitric acid.

C + 4HNO<sub>3</sub>(conc.) 
$$\longrightarrow$$
 CO<sub>2</sub> + 4NO<sub>2</sub> + 2H<sub>2</sub>O  
Si + 4HNO<sub>3</sub>(conc.)  $\longrightarrow$  SiO<sub>2</sub> + 4NO<sub>2</sub> + 2H<sub>2</sub>O  
Sn + 4HNO<sub>3</sub>(conc.)  $\longrightarrow$  SnO<sub>2</sub> + 4NO<sub>2</sub> + 2H<sub>2</sub>O

#### Classification of Oxides

(Based on Chemical Behaviour)

(i) Acidic oxides: The oxides which dissolve in water to form oxyacids are called acidic oxides. These are also called acid anhydrides of corresponding acids. The oxides combine with bases to form salts and water and with basic oxides form salts only.

These oxides are generally formed by non-metals. Examples are:

 $CO_2$ ,  $B_2O_3$ ,  $SiO_2$ ,  $N_2O_3$ ,  $NO_2$ ,  $N_2O_5$ ,  $P_4O_6$ ,  $P_4O_8$ ,  $P_4O_{10}$ ,  $SO_2$ ,  $Cl_2O_7$ ,  $I_2O_5$  and by metals in higher oxidation states such as  $SnO_2$ ,  $V_2O_5$ ,  $CrO_3$ ,  $Mn_2O_7$ , etc.

$$\begin{array}{c} \text{CO}_2 + \text{H}_2\text{O} \longrightarrow \text{H}_2\text{CO}_3 \\ \text{SO}_3 + \text{H}_2\text{O} \longrightarrow \text{H}_2\text{SO}_4 \\ \text{SO}_2 + \text{H}_2\text{O} \longrightarrow \text{H}_2\text{SO}_3 \\ \text{N}_2\text{O}_5 + \text{H}_2\text{O} \longrightarrow \text{2HNO}_3 \\ \text{N}_2\text{O}_3 + \text{H}_2\text{O} \longrightarrow \text{2HNO}_2 \\ \text{P}_4\text{O}_6 + 6\text{H}_2\text{O} \longrightarrow \text{4H}_3\text{PO}_3 \\ \text{P}_4\text{O}_{10} + 6\text{H}_2\text{O} \longrightarrow \text{4H}_3\text{PO}_4 \\ \text{Cl}_2\text{O}_7 + \text{H}_2\text{O} \longrightarrow \text{2HClO}_4 \\ \text{SnO}_2 + \text{H}_2\text{O} \longrightarrow \text{H}_2\text{SnO}_3 \\ \text{Mn}_2\text{O}_7 + \text{H}_2\text{O} \longrightarrow \text{2HMnO}_4 \\ \text{CrO}_3 + \text{H}_2\text{O} \longrightarrow \text{H}_2\text{CrO}_4 \\ \end{array}$$

[Some of the oxides form two oxyacids. These are called mixed anhydrides.

$$2NO_2 + H_2O \longrightarrow HNO_2 + HNO_3$$
  
 $P_4O_8 + 6H_2O \longrightarrow 2H_3PO_3 + 2H_3PO_4$ 

$$\begin{array}{c} \text{SiO}_2 \ + \ 2\text{NaOH} \longrightarrow \text{Na}_2\text{SiO}_3 \ + \ \text{H}_2\text{O} \\ \text{Oxide} \qquad \text{Base} \qquad \qquad \text{Salt} \qquad \text{Water} \\ \\ B_2\text{O}_3 \ + \ 6\text{NaOH} \longrightarrow 2\text{Na}_3\text{BO}_3 \ + \ 3\text{H}_2\text{O} \\ \\ P_4\text{O}_{10} \quad + \ 12\text{NaOH} \longrightarrow 4\text{Na}_3\text{PO}_4 \ + \ 6\text{H}_2\text{O} \\ \text{Acidic oxide} \qquad \qquad \text{Salt} \\ \\ \text{SiO}_2 \ + \ \text{CaO} \longrightarrow \text{CaSiO}_3 \\ \\ \text{SO}_3 \ + \ \text{PbO} \longrightarrow \text{PbSO}_4 \\ \end{array}$$

(ii) Basic oxides: The oxides which either dissolve in water to form alkalies or combine with acids to form salts and water or combine with acidic oxides to form salts are called basic oxides. These oxides are formed by metals. Oxides may be ionic or covalent in nature.

$$Na_2O + H_2O \longrightarrow 2NaOH$$
 $CaO + H_2O \longrightarrow Ca(OH)_2$ 
 $CuO + H_2SO_4 \longrightarrow CuSO_4 + H_2O$ 
 $FeO + H_2SO_4 \longrightarrow FeSO_4 + H_2O$ 
 $BaO + 2HC1 \longrightarrow BaCl_2 + H_2O$ 
 $PbO + SO_3 \longrightarrow PbSO_4$ 

(iii) Neutral oxides: The oxides which neither combine with acids nor with bases to form salts.

Examples: CO, H<sub>2</sub>O, N<sub>2</sub>O, NO, etc.

(iv) Amphoteric orides: The oxides which react with acids and bases both are termed amphoteric.

**Examples :** ZnO,  $Al_2O_3$ , BeO,  $Sb_2O_3$ ,  $Cr_2O_3$ , PbO,  $PbO_2$ , etc.

$$ZnO + 2NaOH \longrightarrow Na_2ZnO_2 + H_2O$$
  
 $ZnO + 2HCl \longrightarrow ZnCl_2 + H_2O$   
 $Al_2O_3 + 2NaOH \longrightarrow 2NaAlO_2 + H_2O$   
 $Al_2O_3 + 6HCl \longrightarrow 2AlCl_3 + 3H_2O$   
 $PbO + 2NaOH \longrightarrow Na_2PbO_2 + H_2O$   
 $PbO + H_2SO_4 \longrightarrow PbSO_4 + H_2O$   
 $Cr_2O_3 + 2NaOH \longrightarrow Na_2Cr_2O_4 + H_2O$   
 $Cr_2O_3 + 3H_2SO_4 \longrightarrow Cr_2(SO_4)_3 + 3H_2O$ 

(v) Compound or mixed oxides: Oxides which behave as mixture of two simple oxides.

#### **Examples:**

$$Pb_3O_4(2PbO + PbO_2)$$
,  $Fe_3O_4(FeO + Fe_2O_3)$ ,  $Mn_3O_4(2MnO + MnO_2)$ 

(vi) Peroxides: The oxides when treated with dilute acids form hydrogen peroxide. These oxides are considered as derivatives of  $H_2O_2$  and contain peroxo linkage in their molecules.

**Examples :** 
$$Na_2O_2$$
,  $K_2O_2$ ,  $BaO_2$ , etc.  
 $Na_2O_2 + H_2SO_4(dil.) \longrightarrow Na_2SO_4 + H_2O_2$ 

$$BaO_2 + H_2SO_4(dil.) \longrightarrow BaSO_4 + H_2O_2$$

Na<sub>2</sub>O<sub>2</sub> can be written as Na—O—O—Na. The linkage —O—O— is called peroxo linkage.

(vii) Dioxides: Like peroxides, these also contain excess of oxygen but do not form  $H_2O_2$  with dilute acids. They evolve chlorine with concentrated HCl and oxygen with concentrated  $H_2SO_4$ .

Examples: PbO<sub>2</sub>, MnO<sub>2</sub>

$$MnO_2 + 4HCl \text{ (conc.)} \longrightarrow MnCl_2 + Cl_2 + 2H_2O$$

$$2MnO_2 + 2H_2SO_4 \text{ (conc.)} \longrightarrow 2MnSO_4 + O_2 + 2H_2O$$

(viii) Suboxides: The oxides which contain less oxygen than expected from the normal valency of the elements are termed suboxides.

**Examples:** Carbon suboxide, C<sub>3</sub>O<sub>2</sub>; lead suboxide, Pb<sub>2</sub>O; nitrous oxide, N<sub>2</sub>O.

(ix) Superoxides: These oxides contain  $O_2^-$  ion. The superoxides known are  $KO_2$ ,  $RbO_2$  and  $CsO_2$ . These react with water to give hydrogen peroxide and oxygen.

$$12KO_2 + 2H_2O \longrightarrow 2KOH + H_2O_2 + O_2$$

#### 11.6 OZONE

**Historical:** In 1758, **Van Marum** observed a rotten smell when an electric discharge was passed through air. In 1840, **Schonbien** attributed that the rotten smell was due to formation of a new gas which he named **ozone**. The name ozone comes from the Greek word "ozo" meaning "smell". In 1866, **Sorret** established its formula, O<sub>3</sub>, and pointed out that the ozone is an allotrope of oxygen.

Occurrence: Ozone is present in sufficient amounts in the atmosphere at higher altitudes, *i.e.*, 12 to 15 miles above earth's surface. It is formed from oxygen present there, under the influence of ultraviolet rays from sun. Near earth's surface it is decomposed by dust particles. In small amounts, it occurs near the sea side or big lakes where it is formed by slow evaporation of water.

#### **Laboratory Preparation**

Ozone is obtained by passing silent electric discharge through dry oxygen. It is believed that some of the oxygen molecules dissociate and then atomic oxygen combines with oxygen molecules to form ozone.

$$O_{2} \xrightarrow{\text{Energy}} O + O$$

$$O_{2} + O \longrightarrow O_{3}$$

$$3O_{2} \Longrightarrow 2O_{3} - \text{energy}$$

The mixture obtained consists of 5-10% ozone by volume and the mixture is called **ozonised oxygen.** The apparatus used for this purpose is known as ozoniser. The commonly used ozonisers are:

(i) Siemen's ozoniser and (ii) Brodie's ozoniser

#### (i) Siemen's ozoniser

It consists of two concentric metal or glass tubes sealed together at one end (Fig. 11.7).

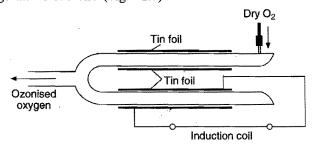

Fig. 11.7

The inner surface of inner tube and outer surface of the outer tube are coated with tin foil. The inner and outer coatings are connected with the two terminals of an induction coil. A current of dry oxygen at low temperature is passed in from one end. When the current is put on, the oxygen is partially converted into ozone. Ozonised oxygen come out from other end and is collected. It contains about 10% ozone, the percentage can be increased upto 15% if temperature is lowered to 5°C.

#### (ii) Brodie's ozoniser

It is shown in Fig. 11.8. The annular space is surrounded on both sides by dilute sulphuric acid in which platinum electrodes are dipped. These electrodes are connected to an

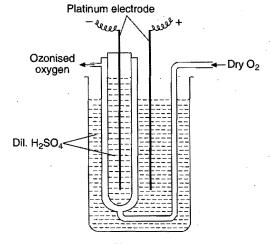

Fig. 11.8

induction coil. Oxygen passing through the annular space is subjected to silent electric discharge and is partially converted into ozone.

#### **Recovery of Pure Ozone from Ozonised Oxygen**

The ozonised oxygen is passed through a spiral cooled by liquid air. Ozone condenses as its condensation temperature is –112.4°C. The liquid ozone thus obtained may contain some dissolved oxygen. This liquid is fractionally distilled to get pure ozone.

#### **Some Reactions Forming Ozone**

(i) Fluorine reacts with water at a very low temperature when mixture of ozonised oxygen is formed.

$$\begin{array}{l}
2F_2 + 2H_2O \longrightarrow 4HF + O_2 \\
3F_2 + 3H_2O \longrightarrow 6HF + O_3
\end{array}$$
Ozonised oxygen

(ii) By action of ultra-violet rays, oxygen can be converted into ozone.

$$O_2 \xrightarrow{UV} O + O$$

$$O_2 + O \longrightarrow O_3$$

(iii) The electrolysis of acidified water with high current density and platinum anode yields ozone on the anode. Nascent oxygen discharged at anode combines with molecular oxygen to form ozone.

#### Properties

#### Physical properties:

- (a) It is a pale blue gas with a characteristic strong smell.
- (b) It can be liquefied to pale blue liquid at −112.4°C. At −249.7°C, it forms violet black crystals.
  - (c) It is heavier than air.
- (d) It is slightly soluble in water but more soluble in turpentine oil, glacial acetic acid, or carbon tetrachloride.
- (e) When inhaled in small amounts, it causes headache and nausea.
  - (f) It is diamagnetic in nature.

#### Chemical properties:

(a) **Decomposition:** It is unstable and decomposes completely into oxygen at 300°C.

$$2O_3 \xrightarrow{\text{Heat}} 3O_2 + 68 \text{ kcal}$$

 $MnO_2$ , platinum black, silver, lead dioxide, etc., decompose ozone at ordinary temperature, *i.e.*, they catalyse its decomposition.

**(b) Oxidising nature:** Due to the ease with which it can liberate nascent oxygen, it acts as a powerful oxidising agent. The potential equation is:

$$O_3 \longrightarrow O_2 + O$$

The oxidation potential in acid medium is +2.07 V.

$$O_3 + 2H^+ + 2e^- \longrightarrow O_2 + H_2O \qquad E^\circ = +2.07 \text{ V}$$

[There are only three more substances which have oxidation potentials higher than +2.07 V. These are fluorine, atomic oxygen and oxygen fluoride, OF<sub>2</sub>]. Due to high value of oxidation potential it acts as a strong oxidising agent.

**Examples:** (i) It oxidises HCl into Cl<sub>2</sub>, HBr into Br<sub>2</sub> and HI into iodine.

$$O_{3} \longrightarrow O_{2} + O$$

$$2HCl + O \longrightarrow H_{2}O + Cl_{2}$$

$$2HCl + O_{3} \longrightarrow H_{2}O + Cl_{2} + O_{2}$$

(ii) Acidified ferrous sulphate into ferric sulphate.

$$\begin{array}{c}
O_3 \longrightarrow O_2 + O \\
\hline
2FeSO_4 + H_2SO_4 + O \longrightarrow Fe_2(SO_4)_3 + H_2O \\
\hline
2FeSO_4 + H_2SO_4 + O_3 \longrightarrow Fe_2(SO_4)_3 + H_2O + O_2
\end{array}$$

(iii) It liberates iodine from neutral KI solution.

$$O_{3} \longrightarrow O_{2} + O$$

$$2KI + H_{2}O + O \longrightarrow 2KOH + I_{2}$$

$$2KI + H_{2}O + O_{3} \longrightarrow 2KOH + I_{2} + O_{2}$$

(iv) Lead sulphide (black) is oxidised to lead sulphate (colourless).

$$\begin{array}{c}
[O_3 \longrightarrow O_2 + O] \times 4 \\
PbS + 4O \longrightarrow PbSO_4 \\
\hline
PbS + 4O_3 \longrightarrow PbSO_4 + 4O_2
\end{array}$$

Similarly, CuS, ZnS and CdS are oxidised to  $CuSO_4$ ,  $ZnSO_4$  and  $CdSO_4$ , respectively.

(v) It oxidises nitrites into nitrates, sulphites into sulphates, arsenites to arsenates, manganate to permanganate and ferrocyanide to ferricyanide.

$$\begin{array}{c} NaNO_2 + O_3 \longrightarrow NaNO_3 + O_2 \\ Na_2SO_3 + O_3 \longrightarrow Na_2SO_4 + O_2 \\ Na_3AsO_3 + O_3 \longrightarrow Na_3AsO_4 + O_2 \\ Sodium \ arsenite \qquad Sodium \ arsenate \\ 2K_2MnO_4 + H_2O + O_3 \longrightarrow 2KMnO_4 + 2KOH + O_2 \\ Potassium \\ manganate \qquad permanganate \\ 2K_4Fe(CN)_6 + H_2O + O_3 \longrightarrow 2K_3Fe(CN)_6 + 2KOH + O_2 \end{array}$$

$$2K_4Fe(CN)_6 + H_2O + O_3 \longrightarrow 2K_3Fe(CN)_6 + 2KOH + O_2$$
Potassium
ferrocyanide

Potassium
ferricyanide

(vi) Moist iodine is oxidised to iodic acid.

$$\frac{[O_3 \longrightarrow O_2 + O] \times 5}{I_2 + H_2O + 5O \longrightarrow 2HIO_3}$$

$$\frac{I_2 + H_2O + 5O_3 \longrightarrow 2HIO_3 + 5O_2}{Iodic acid}$$

Similarly; moist sulphur, phosphorus and arsenic are oxidised to their corresponding oxyacids.

$$\begin{array}{c} S + H_2O + 3O_3 \longrightarrow H_2SO_4 + 3O_2 \\ 2P + 3H_2O + 5O_3 \longrightarrow 2H_3PO_4 + 5O_2 \\ 2As + 3H_2O + 5O_3 \longrightarrow 2H_3AsO_4 + 5O_2 \end{array}$$

(vii) H<sub>2</sub>S is oxidised to sulphur.

$$H_2S + O_3 \longrightarrow H_2O + S + O_2$$

(viii) Alkaline KI is oxidised to potassium iodate and periodate.

$$KI + 3O_3 \longrightarrow KIO_3 + 3O_2$$
Potassium iodate

 $KI + 4O_3 \longrightarrow KIO_4 + 4O_2$ 
Pot. periodate

(ix) Dry iodine is oxidised to yellow powder, I<sub>4</sub>O<sub>9</sub>.

$$\begin{array}{c}
[O_3 \longrightarrow O_2 + O] \times 9 \\
2I_2 + 9O \longrightarrow I_4O_9 \\
\hline
2I_2 + 9O_3 \longrightarrow I_4O_9 + 9O_2
\end{array}$$

(x) Silver metal is blackened due to alternate oxidation of the metal and reduction of oxide.

$$\begin{array}{c} 2 Ag + O_3 \longrightarrow Ag_2O + O_2 \\ Ag_2O + O_3 \longrightarrow 2Ag + 2O_2 \end{array}$$

(xi) Mercury in presence of ozone is oxidised to suboxide which dissolves in mercury. It starts sticking to glass and loses mobility. Hence, mercury loses its meniscus in contact with ozone. This is termed as the tailing of mercury.

$$2Hg + O_3 \longrightarrow Hg_2O + O_2$$

(xii) Ozone reacts with KOH and forms potassium ozonide, KO3, which is an orange coloured solid and contains paramagnetic O<sup>3-</sup> ion.

$$2KOH + 5O_3 \longrightarrow 2KO_3 + 5O_2 + H_2O$$

In all above reactions, oxygen is evolved.

There are few reactions in which whole of the oxygen is used up in the process of oxidation.

1. Oxidises SO<sub>2</sub> to SO<sub>3</sub>.

$$3SO_2 + O_3 \longrightarrow 3SO_3$$

2. Acidified stannous chloride is oxidised to stannic chloride.

$$3SnCl_2 + 6HCl + O_3 \longrightarrow 3SnCl_4 + 3H_2O$$

(c) Bleaching property: It is a good bleaching agent. The bleaching action is due to its oxidising action on the organic matter.

It bleaches oil, ivory, flour, starch, waxes, wood pulp, etc.

(d) Formation of ozonides: Ozone reacts with unsaturated organic compounds containing double bonds. The products formed are known as ozonides. The ozonides break up when treated with water to form carbonyl compounds. The process is called **ozonolysis**. H<sub>2</sub>O<sub>2</sub> is evolved in most of the cases.

$$R$$
—CH = CH— $R'$  + O<sub>3</sub> — O CH $R'$ —O Ozonide

$$O \leftarrow CHR - O \rightarrow R - CH = O + R' - CH = O + H_2O_2$$

$$CHR' - O \rightarrow R - CH = O + R' - CH = O + H_2O_2$$
Mixture of Aldehydes

(e) Reaction with peroxide: Reaction of ozone with peroxide results in their mutual reduction with the liberation of oxygen.

$$BaO_2 + O_3 \longrightarrow BaO + 2O_2$$
  
 $H_2O_2 + O_3 \longrightarrow H_2O + 2O_2$ 

#### Uses

- (i) As a germicide and disinfectant for sterilizing water and improving the atmosphere of crowded places like tube railways, mines and cinema halls.
- (ii) As a bleaching agent for oils, flour, ivory, wax and delicate fabrics.
  - (iii) In the manufacture of artificial silk, synthetic silk,

synthetic camphor and potassium permanganate (by oxidation of potassium manganate).

- (iv) It is used for detecting the position of double bond in the unsaturated organic compounds.
- (v) In destroying odours that arise from cold storage rooms, kitchens of big hotels or slaughter houses.

#### Structure of Ozone

Trambaruls (1953) and Hughes (1956) have pointed out from the studies of ozone by electron diffraction that ozone molecule is V-shaped with a bond angle of 116.8° and O-O bond length 1.278 Å. The central oxygen atom in ozone is  $sp^2$ -hybridized.

The bond length is intermediate between that for a single bond (1.48 Å as in  $H_2O_2$ ) and for a double bond (1.21 Å as in O<sub>2</sub>). Ozone is, therefore, considered to be a resonance hybrid of the following two forms:

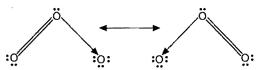

Fig. 11.10

**Tests of ozone:** (i) It has a strong rotten smell.

- (ii) Metallic mercury loses its fluidity in contact with ozone.
- (iii) It turns an alcoholic solution of benzidine brown.
- (iv) It turns an alcoholic solution of tetramethyl base violet.
- (v) It turns starch-iodide paper blue.

Ozone (O<sub>3</sub>)

11.7 SULPHUR

The name sulphur has been derived from Sanskrit word *Sulveri* meaning killer of copper. The elementary nature of sulphur was established by **Lavoisier** in 1777.

**Occurrence:** It is widely distributed in nature both in free and combined state. The free sulphur is found in the volcanic regions of Sicily, Iceland, Japan, Mexico and Louisiana and Texas states of U.S.A. Sulphur in American deposits occurs at a depth of about 700–1200 feet while Sicily deposits are associated with 75% clay and gypsum. These are the two main sources of world supply of sulphur. In small quantities, it occurs in New Zealand, Russia, Baluchistan (Pakistan) and Kangra (India).

It occurs in abundance in the combined state as:

(i) **Sulphide ores,** e.g., Zinc blende or sphalerite (ZnS), galena (PbS), cinnabar (HgS), copper pyrites (CuFeS<sub>2</sub>) and iron pyrites (FeS<sub>2</sub>). Iron pyrite is called "fool's gold" because of its misleading resemblance to gold metal.

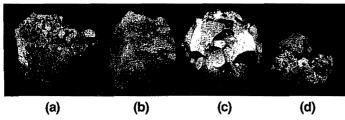

Fig. 11.11 Sulphide ores (from left to right): (a) Galena, PbS; (b) Cinnabar, HgS; (c) Pyrite, FeS<sub>2</sub>; and (d) Sphalerite, ZnS

- (ii) Sulphate ores, e.g., Gypsum (CaSO<sub>4</sub>·2H<sub>2</sub>O), barytes (BaSO<sub>4</sub>), Epsom salt (MgSO<sub>4</sub>·7H<sub>2</sub>O) and celesite (SrSO<sub>4</sub>).
- (iii) H<sub>2</sub>S and SO<sub>2</sub> in volcanic gases. H<sub>2</sub>S in spring waters, coal gas, sewage gas, etc.
- (iv) Organic compounds of plant and animal origin, e.g., onion, garlic, mustard, eggs, proteins, hair, wool, etc., contain organic sulphur compounds.

Sulphur is also found as deposits of the native element (brium-stone), which are formed by bacterial action on H<sub>2</sub>S.

**Extraction:** (i) To extract underground sulphur, **Frasch process** is used. Three concentric pipes are sunk deep into the ground. Super heated water at 170°C is forced down through the outer pipe into sulphur deposits, which heats the rock above the melting point of sulphur, 119°C. By this way sulphur gets melted. Compresed air blown through innermost pipe forcess the molten sulphur to come out through the third pipe,

as a liquid to the surface where it is allowed to solidify. 99.5% pure sulphur is obtained by this process.

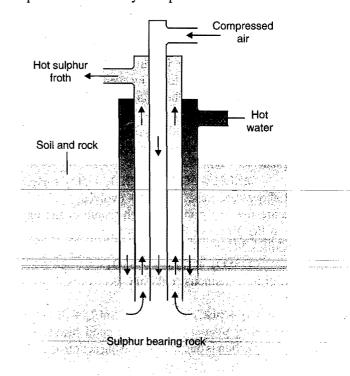

Fig. 11.12 The Frasch process for extraction of sulphur

(ii) Sulphur as a byproduct: (a) From alkali waste of Leblanc's process: The alkali waste (mainly CaS) is suspended in water and carbon dioxide is circulated. Hydrogen sulphide is liberated which is burnt in an insufficient supply of air.

$$CaS + H2O + CO2 \longrightarrow CaCO3 + H2S$$

$$2H2S + O2 \longrightarrow 2H2O + 2S$$
(Air)

(b) From the spent oxides of the gas works: It contains ferric sulphide  $(Fe_2S_3)$ . It is exposed to air for a few days when sulphur is deposited.

$$2Fe_2S_3 + 3O_2 \longrightarrow 2Fe_2O_3 + 6S$$

(c) From iron pyrites: Iron pyrites is a good source of sulphur. It is recovered when pyrite is distilled.

$$3FeS_2 \xrightarrow{\quad Distillation \quad } Fe_3S_4 + 2S$$

Pure sulphur is obtained by boiling impure sulphur at 444°C. The vapours of sulphur evolved are condensed on the cold walls as a light yellow powder.

#### Allotropic Forms

Sulphur exists in several allotropic forms, the important ones are described ahead:

1. Rhombic or octahedral or α-sulphur: This is the common form of sulphur. It is pale yellow in colour. It melts at 114.5°C. Its specific gravity is 2.06. It is insoluble in water but readily soluble in carbon disulphide. It dissolves to some extent in benzene, alcohol and ether. It is a crystalline variety and consists of S<sub>8</sub> structural units packed together into octahedral shape. This is the stable variety at ordinary temperature and all other forms gradually change into this form. This form gets converted into monoclinic form when heated above 96°C.

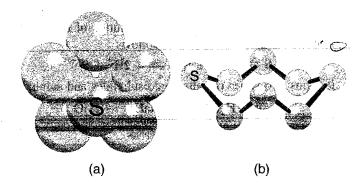

Fig. 11.13 Structure of S<sub>8</sub> molecule

2. Monoclinic or prismatic or  $\beta$ -sulphur: This form is formed by melting sulphur in a dish and cooling till crust is formed. Two holes are made in the crust and liquid is poured out. On removing the crust, needle shaped crystals of monoclinic sulphur are obtained.

This form of sulphur is stable above 95.6°C. The crystals are amber yellow in colour and have specific gravity of 1.96. Crystals melt at 119°C. It is also soluble in carbon disulphide. Below 95.6°C, it changes into rhombic form. Thus, 95.6°C is the transition temperature.

Rhombic sulphur 

95.6°C → Monoclinic sulphur

3. Plastic sulphur: This is obtained when boiling sulphur is poured into cold water. It is soft rubber like mass which hardens on standing and gradually changes into rhombic sulphur. It is amber-brown in colour and has specific gravity of 1.95. It is insoluble in CS<sub>2</sub> and has no sharp melting point. It consists of a completely random arrangement of chains of sulphur atoms.

#### Action of heat on sulphur

Ordinary sulphur melts at 114°C to a pale yellow mobile liquid. On heating further instead of becoming more mobile, it grows thicker. The colour changes to reddish brown and then to almost black. At about 180°C, the viscosity increases so much that it cannot be poured out by inverting the container. At about 200°C the viscosity begins to decrease and at its boiling point of 444°C, the liquid is again mobile. No definite explanation of these observations is known uptil now.

Uses: Sulphur is used:

- (i) in the manufacture of SO<sub>2</sub>, H<sub>2</sub>SO<sub>4</sub>, CS<sub>2</sub>, matches, gun powder, fire works, etc.
- (ii) as a disinfectant for houses and for destroying bacteria, fungi, insects, etc. (vapours of sulphur are poisonous for bacteria, etc., but not for human beings).
- (iii) for vulcanising rubber and in the manufacture of sulphur dyes.
  - (iv) in medicine, for internal as well as external applications.

#### 11.8 COMPOUNDS OF SULPHUR

The main compounds of sulphur are,

- 1. Hydrogen sulphide or sulphuretted hydrogen (H<sub>2</sub>S)
- 2. Oxides of sulphur
- 3. Oxyacids of sulphur

#### 1. Hydrogen Sulphide or Sulphuretted Hydrogen (H<sub>2</sub>S)

**Occurrence:** It occurs in volcanic gases, sewage gases, coal gas and in several spring waters. It is found in small amounts in atmosphere, where it comes from the heating of coal and decay of animal and vegetable matter containing sulphur compounds.

**Laboratory preparation**: Hydrogen sulphide is obtained in the laboratory by the action of dilute sulphuric acid on ferrous sulphide.

$$FeS + H_2SO_4 \longrightarrow FeSO_4 + H_2S$$

As the gas is required intermittently in the laboratory, it is prepared in the well known Kipp's apparatus (Fig. 11.14).

The gas obtained is always impure as it is contaminated with hydrogen. Pure hydrogen sulphide can be prepared by the action of pure HCl on antimony sulphide.

$$Sb_2S_3 + 6HC1 \longrightarrow 2SbCl_3 + 3H_2S$$

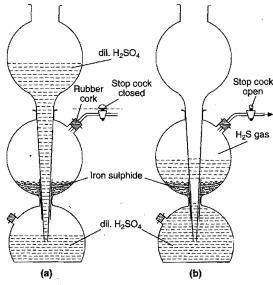

Fig. 11.14

#### **■** Properties

**Physical properties:** (a) It is a colourless gas with unpleasant odour of rotten eggs.

- (b) It is slightly heavier than air and moderatory soluble in cold water. The solubility decreases in hot water.
- (c) It is poisonous in nature. It produces headache when inhaled in small quantities but may cause death when inhaled for a long time.
- (d) It can be easily liquefied by pressure. The boiling point is about -60°C. It freezes to a transparent solid at -85.6°C.

**Chemical properties:** (a) Combustibility: The gas burns with a blue flame in oxygen or air forming sulphur dioxide and water.

$$2H_2S + 3O_2 \longrightarrow 2H_2O + 2SO_2$$

In restricted supply of oxygen, sulphur is formed due to incomplete combustion.

$$2H_2S + O_2 \longrightarrow 2H_2O + 2S$$

**(b) Thermal decomposition:** The gas is not so stable as water. It decomposes on heating. The decomposition starts at 310°C and completes at 1700°C.

$$H_2S \longrightarrow H_2 + S$$

- (c) Reducing nature: Hydrogen sulphide acts as a strong reducing agent as it decomposes evolving hydrogen. The following are the important examples of its reducing action:
  - (i) It reduces halogens into corresponding hydracids.

$$H_2S + X_2 \longrightarrow 2HX + S$$
  $(X_2 = F_2, Cl_2, Br_2 \text{ or } I_2)$ 

(ii) It reduces ferric chloride to ferrous chloride.

$$2FeCl_3 + H_2S \longrightarrow 2FeCl_2 + 2HCl + S$$

(iii) Sulphur dioxide is reduced to sulphur in presence of moisture.

$$SO_2 + 2H_2S \longrightarrow 3S + 2H_2O$$

The occurrence of sulphur in volcanic regions is attributed due to the above reaction as both gases are present in volcanic gases.

(iv) H<sub>2</sub>O<sub>2</sub> is reduced to water.

$$H_2O_2 + H_2S \longrightarrow 2H_2O + S$$

(v)  $O_3$  is reduced to  $O_2$ .

$$H_2S + O_3 \longrightarrow H_2O + S + O_2$$

(vi) HNO<sub>3</sub> is reduced to NO<sub>2</sub>.

$$2HNO_3 \longrightarrow H_2O + 2NO_2 + O$$

$$H_2S + O \longrightarrow H_2O + S$$

$$2HNO_3 + H_2S \longrightarrow 2NO_2 + S + 2H_2O$$

(vii) H<sub>2</sub>SO<sub>4</sub> is reduced to SO<sub>2</sub>.

$$\begin{array}{c} H_2SO_4 \longrightarrow H_2O + SO_2 + O \\ H_2S + O \longrightarrow H_2O + S \\ \hline H_2SO_4 + H_2S \longrightarrow 2H_2O + SO_2 + S \end{array}$$

[Note:  $H_2S$  cannot be dried by conc.  $H_2SO_4$  because it oxidises  $H_2S$  to

It is therefore dried by passing through CaCl<sub>2</sub> or P<sub>4</sub>O<sub>10</sub>.]

(viii) Acidified KMnO<sub>4</sub> is decolourised.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$
$$[H_2S + O \longrightarrow H_2O + S] \times 5$$

$$2KMnO_4 + 3H_2SO_4 + 5H_2S \longrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 5S$$

(ix) Acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is reduced forming green chromic sulphate.

$$K_2Cr_2O_7 + 4H_2SO_4 \rightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$
  
 $[H_2S + O \rightarrow H_2O + S] \times 3$ 

$$K_2Cr_2O_7 + 4H_2SO_4 + 3H_2S \rightarrow K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 3S$$

(d) Acidic nature: The aqueous solution of H<sub>2</sub>S acts as a weak dibasic acid. It ionises as follows:

$$H_2S \rightleftharpoons H^+ + HS^- \rightleftharpoons 2H^+ + S^-$$

It forms two series of salts, hydrosulphides and sulphides.

$$\begin{array}{c} NaOH + H_2S \longrightarrow \underset{Sodium\, hydro-}{NaHS} + H_2O \\ & \\ & \\ sulphide \end{array}$$

$$2NaOH + H_2S \longrightarrow Na_2S + 2H_2O$$
 Sodium sulphide

(e) Reaction with metals and metal oxides: H<sub>2</sub>S reacts with metals and metal oxides to form corresponding sulphides.

$$\begin{split} 2\text{Na} + \text{H}_2\text{S} &\longrightarrow \text{Na}_2\text{S} + \text{H}_2 \\ \text{Cu} + \text{H}_2\text{S} &\longrightarrow \text{CuS} + \text{H}_2 \\ 2\text{Ag} + \text{H}_2\text{S} &\longrightarrow \text{Ag}_2\text{S} + \text{H}_2 \\ \text{Pb} + \text{H}_2\text{S} &\longrightarrow \text{PbS} + \text{H}_2 \\ \text{CaO} + \text{H}_2\text{S} &\xrightarrow{\text{Heat}} \text{CaS} + \text{H}_2\text{O} \\ \text{ZnO} + \text{H}_2\text{S} &\xrightarrow{\text{Heat}} \text{ZnS} + \text{H}_2\text{O} \end{split}$$

- (f) Action on salts: Hydrogen sulphide reacts with salts of various metals forming corresponding sulphides. The metal sulphides can be divided into three groups.
- (i) Sulphides precipitated in acidic medium: These are sulphides of Hg, Ag, Pb, Cu, Bi, Cd, As, Sb and Sn.

$$\begin{array}{c} \text{CuSO}_4 + \text{H}_2\text{S} \longrightarrow \text{CuS} + \text{H}_2\text{SO}_4 \\ \text{Pb}(\text{CH}_3\text{COO})_2 + \text{H}_2\text{S} \longrightarrow \text{PbS} + 2\text{CH}_3\text{COOH} \\ \text{CdSO}_4 + \text{H}_2\text{S} \longrightarrow \text{CdS} + \text{H}_2\text{SO}_4 \\ \text{HgS}, \text{CuS}, \text{PbS} \longrightarrow \text{Black} \\ \text{Bi}_2\text{S}_3 \longrightarrow \text{Brown} \\ \text{CdS} \longrightarrow \text{Yellow} \end{array} \right\} \quad \begin{array}{c} \text{Insoluble in yellow} \\ \text{ammonium sulphide} \\ \text{SnS}_2, \text{As}_2\text{S}_3 \longrightarrow \text{Yellow} \\ \text{Sb}_2\text{S}_3 \longrightarrow \text{Orange} \\ \text{SnS} \longrightarrow \text{Chocolate} \end{array} \right\} \quad \begin{array}{c} \text{Soluble in yellow} \\ \text{ammonium sulphide} \\ \end{array}$$

(ii) Sulphides precipitated in alkaline medium: These are the sulphides of Zn, Co, Ni, Mn and Fe.

$$MnCl_2 + H_2S \longrightarrow MnS + 2HCl$$
  
 $Ni(NO_3)_2 + H_2S \longrightarrow NiS + 2HNO_3$ 

$$ZnSO_4 + H_2S \longrightarrow ZnS + H_2SO_4$$

CoS, NiS; Black, ZnS; White, MnS; Flesh coloured

- (iii) Sulphides which are precipitated neither in acidic nor in alkaline medium: These are the sulphides of Cr, Al, Mg, Ba, Sr, Ca, K and Na.
- (g) Formation of polysulphides: Polysulphides of metals are obtained by passing  $H_2S$  through their hydroxides.

$$Ca(OH)_2 + H_2S \longrightarrow CaS + 2H_2O$$
  
 $CaS + 4H_2S \longrightarrow CaS_5 + 4H_2$ 

On passing excess of H<sub>2</sub>S through ammonium sulphide, yellow ammonium sulphide is formed.

$$2NH_4OH + H_2S \longrightarrow (NH_4)_2S + 2H_2O$$

$$(NH_4)_2S + xH_2S \longrightarrow (NH_4)_2S_{x+1} + xH_2$$
Ammonium
polysulphide

#### Uses

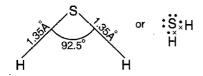

- (i) It is an important laboratory reagent for the detection of basic radicals in qualitative analysis.
- (ii) It is used for the preparation of metallic sulphides many of which find use in paint industry.
  - (iii) It is used as a reducing agent.

#### Tests of hydrogen sulphide

- (i) It has unpleasant odour resembling that of rotten eggs.
- (ii) It turns lead acetate paper black.
- (iii) It gives a violet colouration with a solution of sodium nitroprusside.

#### ■ Structure of H<sub>2</sub>S

The shape of the H<sub>2</sub>S molecule is similar to that of the water molecule, *i.e.*, V-shaped structure with bond length (H—S) 1.35 Å and bond angle (H—S—H) 92.5°.

#### 2. Oxides of Sulphur

Sulphur forms a number of oxides. These are:

- (i) Sulphur suboxide, S<sub>2</sub>O (colourless gas)
- (ii) Sulphur monoxide, SO (colourless gas)
- (iii) Sulphur sesquioxide, S<sub>2</sub>O<sub>3</sub> (green crystalline solid)
- (iv) Sulphur dioxide, SO<sub>2</sub> (colourless gas)
- (v) Sulphur trioxide, SO<sub>3</sub> (volatile liquid)
- (vi) Sulphur heptoxide, S<sub>2</sub>O<sub>7</sub> (liquid)
- (vii) Sulphur tetroxide, SO<sub>4</sub> (white solid)

Out of these, sulphur dioxide and sulphur trioxide are common and important and described here.

#### (i) Sulphur dioxide, SO<sub>2</sub>

**Preparation:** The following reactions can be used for the preparation of sulphur dioxide.

(a) By burning sulphur in air or oxygen.

$$S + O_2 \longrightarrow SO_2$$

Fig. 11.15 Structure of the SO<sub>2</sub> molecule

$$S + 2H_2SO_4 \xrightarrow{\text{Heat}} 2H_2O + 3SO_2$$

(c) By heating copper or silver with concentrated sulphuric acid.

$$Cu + 2H_2SO_4 \longrightarrow CuSO_4 + 2H_2O + SO_2$$
  
 $2Ag + 2H_2SO_4 \longrightarrow Ag_2SO_4 + 2H_2O + SO_2$ 

(d) By reacting sodium sulphite or sodium hydrosulphite with dil. HCl.

$$Na_2SO_3 + 2HCl \longrightarrow 2NaCl + H_2O + SO_2$$
  
 $NaHSO_3 + HCl \longrightarrow NaCl + H_2O + SO_2$ 

(e) By roasting of sulphides.

$$2ZnS + 3O_2 \longrightarrow 2ZnO + 2SO_2$$
  
 $4FeS_2 + 11O_2 \longrightarrow 2Fe_2O_3 + 8SO_2$ 

The reactions (b), (c) and (d) can be used for the preparation of  $SO_2$  in the laboratory while the reactions (a) and (e) are used in industry to obtain  $SO_2$ .

In places where gypsum or anhydrite are found in abundance, sulphur dioxide can be obtained on a large scale by heating gypsum or anhydrite with carbon at about 1000°C.

$$2CaSO_4 + C \longrightarrow 2CaO + 2SO_2 + CO_2$$

#### Properties

**Physical properties:** (a) It is a colourless gas with a pungent, suffocating odour.

- (b) It is heavier than air.
- (c) It is highly soluble in water.
- (d) It can be easily liquefied to a colourless liquid at  $-10^{\circ}$ C and into a snowlike solid at  $-76^{\circ}$ C.

**Chemical properties:** (a) It neither burns nor it helps in burning. However, burning magnesium and potassium continue to burn in its atmosphere.

$$3Mg + SO_2 \longrightarrow 2MgO + MgS$$

$$4K + 3SO_2 \longrightarrow K_2SO_3 + K_2S_2O_3$$

**(b) Thermal decomposition :** It decomposes at 1200°C producing sulphur trioxide and sulphur.

$$3SO_2 \longrightarrow 2SO_3 + S$$

(c) Acidic nature: It is an acidic oxide. It dissolves in water forming sulphurous acid.

$$SO_2 + H_2O \longrightarrow H_2SO_3$$
 (Sulphurous acid)

The gas is, therefore, known as sulphurous anhydride. It combines with basic oxides and forms sulphites.

$$BaO + SO_2 \longrightarrow BaSO_3$$

It reacts with alkalies forming two series of salts.

$$NaOH + SO_2 \longrightarrow NaHSO_3$$
  
Sod. bisulphite  
 $2NaOH + SO_2 \longrightarrow Na_2SO_3 + H_2O$   
Sod. sulphite

It also decomposes carbonates and bicarbonates evolving CO<sub>2</sub> gas.

$$Na_2CO_3 + 2SO_2 + H_2O \longrightarrow 2NaHSO_3 + CO_2$$

Like CO<sub>2</sub>, it turns lime water milky due to the formation of CaSO<sub>3</sub>. However, if SO<sub>2</sub> is passed for a long time, milkiness disappears due to formation of soluble calcium bisulphite.

$$Ca(OH)_2 + SO_2 \longrightarrow CaSO_3 + H_2O$$

$$(Milkiness)$$

$$CaSO_3 + H_2O + SO_2 \longrightarrow Ca(HSO_3)_2$$

$$Cal. \text{ bisulphite}$$

$$(soluble)$$

(d) Addition reactions: (i) It combines directly with halogens to form sulphuryl halides.

$$SO_2 + Cl_2 \longrightarrow SO_2Cl_2$$
 (Sulphuryl chloride)

(ii) It combines directly with oxygen in presence of a catalyst (platinised asbestos).

$$2SO_2 + O_2 \rightleftharpoons 2SO_3$$

(iii) It directly combines with lead dioxide to form lead sulphate.

$$PbO_2 + SO_2 \longrightarrow PbSO_4$$

(e) **Reducing nature:** The aqueous solution of  $SO_2$  acts as a reducing agent as sulphurous acid changes into sulphuric acid giving nascent hydrogen.

$$H_2O + SO_2 \longrightarrow H_2SO_3$$
  
 $H_2SO_3 + H_2O \longrightarrow H_2SO_4 + 2H$ 

**Examples:** (i) It reduces halogens to their respective hydracids.

$$SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2H$$

$$2H + Cl_2 \longrightarrow 2HCl$$

$$SO_2 + 2H_2O + Cl_2 \longrightarrow H_2SO_4 + 2HCl$$

(ii) Acidified KMnO<sub>4</sub> is reduced, i.e., it is decolourised.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$
$$[SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2H] \times 5$$
$$[2H + O \longrightarrow H_2O] \times 5$$

$$2KMnO_4 + 5SO_2 + 2H_2O \longrightarrow K_2SO_4 + 2MnSO_4 + 2H_2SO_4$$

(iii) Acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is turned green due to formation of chromic sulphate.

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$

$$[SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2H] \times 3$$

$$[2H + O \longrightarrow H_2O] \times 3$$

$$K_2Cr_2O_7 + 3SO_2 + H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O$$
(Green)

(iv) Ferric sulphate is reduced to ferrous sulphate.

$$SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2H$$
  
 $Fe_2(SO_4)_3 + 2H \longrightarrow 2FeSO_4 + H_2SO_4$ 

$$Fe_2(SO_4)_3 + SO_2 + 2H_2O \longrightarrow 2FeSO_4 + 2H_2SO_4$$

(v) It reduces acidified iodates to iodine.

$$[SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2H] \times 5$$

$$2KIO_3 + H_2SO_4 \longrightarrow K_2SO_4 + 2HIO_3$$

$$2HIO_3 + 10H \longrightarrow I_2 + 6H_2O$$

$$2KIO_3 + 5SO_2 + 4H_2O \longrightarrow K_2SO_4 + 4H_2SO_4 + I_2$$

- (f) Oxidising nature: It also acts as an oxidising agent particularly when treated with stronger reducing agents.
  - (i) It oxidises H<sub>2</sub>S into S.

$$2H_2S + SO_2 \longrightarrow 2H_2O + 3S$$

(ii) Metals are oxidised by SO<sub>2</sub>.

$$3Mg + SO_2 \longrightarrow 2MgO + MgS$$
  
 $4K + 3SO_2 \longrightarrow K_2SO_3 + K_2S_2O_3$   
 $3Fe + SO_2 \longrightarrow 2FeO + FeS$ 

(iii) CO is oxidised to CO<sub>2</sub> by SO<sub>2</sub>.

$$2CO + SO_2 \longrightarrow 2CO_2 + S$$

(iv) At 1000°C, it oxidises hydrogen into water.

$$SO_2 + 2H_2 \longrightarrow 2H_2O + S$$

(v) Stannous and mercurous salts are oxidised in presence of excess of HCl.

$$2\operatorname{SnCl}_2 + \operatorname{SO}_2 + 4\operatorname{HCl} \longrightarrow 2\operatorname{SnCl}_4 + 2\operatorname{H}_2\operatorname{O} + \operatorname{S}$$
  
 $2\operatorname{Hg}_2\operatorname{Cl}_2 + \operatorname{SO}_2 + 4\operatorname{HCl} \longrightarrow 4\operatorname{Hg}\operatorname{Cl}_2 + 2\operatorname{H}_2\operatorname{O} + \operatorname{S}$ 

(g) Bleaching action:  $SO_2$  in presence of moisture acts as a bleaching agent. This is due to the reducing nature of  $SO_2$ .

$$SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2H$$

Coloured matter + H ---- Colourless matter

The bleaching is temporary. The bleached matter when exposed to air regains its colour due to oxidation.

#### Uses

- (i) It is used in the manufacture of sulphuric acid and paper from wood pulp (use of bisulphites).
- (ii) It is used as a bleaching agent for delicate articles like wool, silk and straw.
  - (iii) It is used in refining of petroleum and sugar.
- (iv) As a disinfectant for killing disease germs, fungi and certain moulds.

- (v) As a refrigerant in the form of liquid SO<sub>2</sub>.
- (vi) It is used as an antichlor for removing chlorine from a fabric after bleaching.

**Structure:** Already described in section 11.1 (3b).

#### (ii) Sulphur Trioxide, SO<sub>3</sub>

Preparation: Sulphur trioxide is obtained:

(i) by dehydrating sulphuric acid with excess of phosphorus pentoxide.  $6H_2SO_4 + P_4O_{10} \longrightarrow 4H_3PO_4 + 6SO_3$  Fig. 11.16 Structure

(ii) by heating ferric sulphate strongly. of the SO<sub>3</sub> molecule

$$Fe_2(SO_4)_3 \longrightarrow Fe_2O_3 + 3SO_3$$

(iii) by oxidation of SO<sub>2</sub> with oxygen in presence of a catalyst (commercial method).

$$2SO_2 + O_2 \stackrel{Pt}{\rightleftharpoons} 2SO_3$$

Both SO<sub>2</sub> and O<sub>2</sub> should be completely dry. The mixture is passed over platinised asbestos at 400°C, when SO<sub>3</sub> is formed.

#### **Properties**

- (i) SO<sub>3</sub> exists in three allotropic forms:
- (a)  $\alpha$ -SO<sub>3</sub>: It is chemically active form. If forms long transparent ice like crystals. The melting point of this form is 17°C.
- (b)  $\beta$ -SO<sub>3</sub>: It is dimeric (S<sub>2</sub>O<sub>6</sub>). It forms needle like silky white crystals. It melts at 32.5°C. Above 50°C, it changes to \alpha-form.
- (c)  $\gamma$ -SO<sub>3</sub>: It is like  $\beta$ -form and obtained by completely drying β-SO<sub>3</sub>. It melts at 62.2°C under 2 atmospheric pressure.
- (ii) SO<sub>3</sub> is an acidic oxide. It dissolves in water forming sulphuric acid with evolution of heat.

$$SO_3 + H_2O \longrightarrow H_2SO_4 + heat$$

It reacts with basic oxides forming sulphates.

$$CaO + SO_3 \longrightarrow CaSO_4$$
  
 $Na_2O + SO_3 \longrightarrow Na_2SO_4$ 

(iii) It dissolves in concentrated sulphuric acid forming oleum (fuming sulphuric acid).

$$H_2SO_4 + SO_3 \longrightarrow H_2S_2O_7$$

(iv) It dissociates on heating at 1000°C into SO<sub>2</sub> and O<sub>2</sub>.

$$2SO_3 \xrightarrow{1000^{\circ}C} 2SO_2 + O_2$$

(v) It combines with concentrated hydrochloric acid and forms chloro-sulphonic acid, a derivative of sulphuric acid.

$$SO_3 + HCl \longrightarrow SO_2 \cdot (OH)Cl$$
Chloro-sulphonic acid

(vi) SO<sub>3</sub> acts as an oxidising agent.

Examples: 
$$2SO_3 + S \xrightarrow{100^{\circ}C} 3SO_2$$

$$5SO_3 + 2P \longrightarrow 5SO_2 + P_2O_5$$

$$SO_3 + PCl_5 \longrightarrow POCl_3 + SO_2 + Cl_2$$

$$\xrightarrow{Phosphoryl} \text{chloride}$$

$$SO_3 + 2HBr \longrightarrow H_2O + Br_2 + SO_2$$

#### Uses

- (i) In the manufacture of sulphuric acid and oleum.
- (ii) It is used as a drying agent for gases.

**Structure:** Already discussed in section 11.1 (3b).

#### 3. Oxyacids of Sulphur

A large number of oxyacids are known in the case of sulphur either in free state or in the form of salts or both. Oxyacids with S-S links are called thioacids. Acids having sulphur in lower oxidation state belong to -ous series while those having sulphur in higher oxidation state belong to -ic series. For

Sulphurous acid (H<sub>2</sub>SO<sub>3</sub>) O.N. sulphur, +4 Sulphuric acid (H<sub>2</sub>SO<sub>4</sub>) O.N. sulphur, +6

The following are main oxyacids of sulphur:

(1) Sulphurous acid series:	Oxidation Number
(i) Sulphurous acid, H <sub>2</sub> SO <sub>3</sub>	+4
(ii) Thiosulphurous acid, H <sub>2</sub> S <sub>2</sub> O <sub>2</sub>	+1
(iii) Hyposulphurous acid, H <sub>2</sub> S <sub>2</sub> O <sub>4</sub>	+3
(iv) Pyrosulphurous acid, H <sub>2</sub> S <sub>2</sub> O <sub>5</sub>	+4
(2) Sulphuric acid series:	
(i) Sulphuric acid, H <sub>2</sub> SO <sub>4</sub>	+6
(ii) Thiosulphuric acid, H <sub>2</sub> S <sub>2</sub> O <sub>3</sub>	
(iii) Pyrosulphuric acid, H <sub>2</sub> S <sub>2</sub> O <sub>7</sub>	+6
(3) Thionic acid series:	
(i) Dithionic acid, H <sub>2</sub> S <sub>2</sub> O <sub>6</sub>	+5
(ii) Polythionic acid, $H_2S_nO_6$ ( $n = 3, 4, 5, 5, 5, 5, 5, 5, 5, 5, 5, 5, 5, 5, 5,$	, 6)

- (4) Peroxy acid series:
  - (i) Peroxy monosulphuric acid, H<sub>2</sub>SO<sub>5</sub> (Caro's acid)
  - (ii) Peroxy disulphuric acid, H<sub>2</sub>S<sub>2</sub>O<sub>8</sub> (Marshall's acid) +6

Only two oxyacids (sulphurous acid and sulphuric acid) are described below:

#### (1) Sulphurous Acid, H<sub>2</sub>SO<sub>3</sub>

This acid is known only in solution. The solution is obtained by dissolving sulphur dioxide in water.

$$SO_2 + H_2O \longrightarrow H_2SO_3$$

The solution gives a smell of sulphur dioxide which is evolved completely on heating. It is, thus, believed that the acid is present in equilibrium with the free gas.

$$H_2SO_3 \rightleftharpoons H_2O + SO_2$$

Properties: It is a strong dibasic acid. It ionises in two stages.

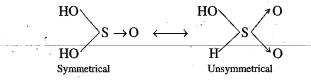

$$H_2SO_3 \rightleftharpoons H^+ + HSO_3^- \rightleftharpoons 2H^+ + SO_3^-$$

It thus forms two series of salts. The salts are known as bisulphites (e.g., NaHSO<sub>3</sub>) and sulphites (e.g., Na<sub>2</sub>SO<sub>3</sub>). The salts are fairly stable.

Like SO<sub>2</sub>, it acts as a reducing agent and shows bleaching properties. These properties have been described under sulphur dioxide.

The acid also acts as an oxidising agent particularly when treated with strong reducing agents.

**Structure:** Sulphurous acid is believed to exist in two forms which are always in equilibrium with each other.

There is more evidence in favour of symmetrical formula,

(i) The preparation of sulphurous acid by the action of H<sub>2</sub>O on thionyl chloride supports symmetrical formula.

$$O \leftarrow S \qquad \begin{array}{c|c} \hline CI & H \\ \hline OH \\ \hline \hline CI & H \\ \hline OH \\ \end{array} \longrightarrow O \leftarrow S \qquad \begin{array}{c|c} OH \\ \hline OH \\ \hline OH \\ \end{array}$$

(ii) The molecule of sulphurous acid readily takes up oxygen or sulphur atom. This can be explained if symmetrical formula is accepted.

$$O \leftarrow S \xrightarrow{OH} O \xrightarrow{+O} S \xrightarrow{OH} OH$$

$$O \leftarrow S \xrightarrow{+S} OH OH$$

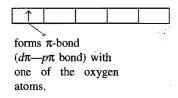

$$O \leftarrow S \xrightarrow{OH} OH$$

The unsymmetrical formula explains the reducing character due to presence of H-S bond and it also accounts for the formation of bisulphite HSO<sub>3</sub> ion.

X-ray analysis of the crystal of Na<sub>2</sub>SO<sub>3</sub> has revealed that SO<sub>3</sub><sup>2-</sup> ion has a pyramidal structure with three oxygen atoms in a triangle. This structure can be possible from sp<sup>3</sup> hybridization of excited sulphur atom giving a tetrahedral configuration

sp<sup>3</sup> hybridization (three sigma bonds with three oxygen atoms and one position occupied by lone pair)

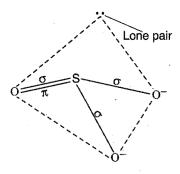

Fig.11.17 Pyramidal structure of SO<sub>3</sub><sup>2-</sup> ion

in which one position is occupied by a lone pair. This distorted tetrahedral structure reduces to pyramidal structure.

#### (2) Sulphuric Acid (oil of vitriol) H<sub>2</sub>SO<sub>4</sub>

Sulphuric acid is considered as the King of chemicals. The prosperity of any country is measured by the amount of sulphuric acid it consumes. Sulphuric acid is, thus, a substance of very great commercial importance as it is used practically in every important industry.

In ancient days, it was called oil of vitriol as it was prepared by distilling ferrous sulphate (Green vitriol).

$$\begin{array}{c} 2FeSO_4 \cdot 7H_2O \xrightarrow{\quad Heat \quad} Fe_2O_3 + H_2SO_4 + SO_2 + 13H_2O \\ \text{(Green vitriol)} \end{array}$$

Native sulphur is the starting material for the preparation of sulphuric acid. Sulphur is burnt and easily converted into sulphur dioxide. The conversion of sulphur dioxide into sulphur trioxide is a matter of difficulty. It requires either a catalyst or a strong oxidising agent. The trioxide dissolves in water to form sulphuric acid. The whole process may be summarised as:

$$S \longrightarrow SO_2 \longrightarrow SO_3 \longrightarrow H_2SO_4$$

For the oxidation of sulphur dioxide into sulphur trioxide. the following reactions may be used:

(i) By atmospheric oxygen in presence of a catalyst,  $V_2O_5$ , at 400°C,

$$2SO_2 + O_2 \xrightarrow{V_2O_5} 2SO_3$$

$$SO_3 + H_2O \longrightarrow H_2SO_4$$

$$5U_3 + H_2U \longrightarrow H_2SU_4$$

(ii) By Cl<sub>2</sub> or Br<sub>2</sub> in presence of moisture,

$$SO_2 + 2H_2O + Cl_2 \longrightarrow H_2SO_4 + 2HCl$$
  
 $SO_2 + 2H_2O + Br_2 \longrightarrow H_2SO_4 + 2HBr$ 

(iii) By H<sub>2</sub>O<sub>2</sub>,

$$SO_2 + H_2O_2 \longrightarrow H_2SO_4$$

(iv) By ozone (O<sub>3</sub>),

$$3SO_2 + O_3 \longrightarrow 3SO_3$$
,

$$SO_3 + H_2O \longrightarrow H_2SO_4$$

(v) By conc. HNO<sub>3</sub>,

$$SO_2 + 2HNO_3 \longrightarrow H_2SO_4 + 2NO_2$$

#### Manufacture

Sulphuric acid is manufactured these days by the following two processes:

- (a) Lead chamber process
- (b) Contact process

#### ■ (a) Lead Chamber Process

**rinciple:** The mixture containing sulphur dioxide, air and nitric oxide when treated with steam, sulphuric acid is formed.

Nitric oxide acts as a catalyst in this reaction. Various mechanisms have been proposed for this reaction.

(i) Berzelius mechanism: Nitric oxide, NO combines with oxygen of the air and is oxidised to nitrogen dioxide (NO<sub>2</sub>).

$$2NO + O_2 \longrightarrow 2NO_2$$

SO<sub>2</sub> is oxidised by nitrogen dioxide into sulphur trioxide which reacts with steam forming sulphuric acid.

$$SO_2 + NO_2 \longrightarrow SO_3 + NO$$
  
 $SO_3 + H_2O \longrightarrow H_2SO_4$ 

NO formed reacts again with oxygen of air and is oxidised to NO<sub>2</sub>. Thus, NO and NO<sub>2</sub> act as oxygen carriers.

(ii) Davy and Lunge mechanism: Nitroso-sulphuric acid is first formed as an intermediate product which then reacts with water forming sulphuric acid.

$$\begin{array}{c} NO + NO_2 \longrightarrow N_2O_3 \\ 2SO_2 + N_2O_3 + O_2 + H_2O \longrightarrow & 2HSO_4 \cdot NO \\ & & \text{Nitroso-sulphuric acid} \\ & & (Intermediate product) \\ 2HSO_4 \cdot NO + H_2O \longrightarrow 2H_2SO_4 + NO + NO_2 \end{array}$$

#### Working and Plant

The plant used for the manufacture of  $H_2SO_4$  in lead chamber process is shown diagrammatically in Fig. 11.18.

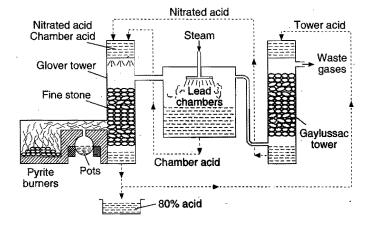

Fig. 11.18

The various parts of the plant and their functions are described below:

(a) **Pyrites or sulphur burners:** These are specially designed brick furnaces where iron pyrite or sulphur is burnt. The supply of air is regulated by sliding doors.

$$4FeS_2 + 11O_2 \longrightarrow 2Fe_2O_3 + 8SO_2$$
$$S + O_2 \longrightarrow SO_2$$

- **(b) Dust chamber:** The dust chamber is provided with baffle walls where dust particles in the gaseous mixture coming from the burners separate due to gravity. This can also be done by using Cottrell electrostatic dust precipitator. [This part is not shown in Fig. 11.18:]
- (c) Nitre pots: Burner gases are then passed through a nitre oven in which potassium nitrate is heated with sulphuric acid. The nitric acid is decomposed by SO<sub>2</sub>.

$$KNO_3 + H_2SO_4 \longrightarrow KHSO_4 + HNO_3$$
  
 $2HNO_3 + 2SO_2 \longrightarrow 2SO_3 + H_2O + NO + NO_2$ 

In modern plants, oxides of nitrogen are produced by the catalytic oxidation of ammonia.

$$4NH_3 + 5O_2 \xrightarrow{\text{Pt. gauze}} 4NO + 6H_2O$$

$$2NO + O_2 \xrightarrow{} 2NO_2$$

- (d) Glover's tower: The tower is made of steel. It is lined inside with sheet of lead or acid resisting bricks. It is packed with flint stone or quartz. There are two tanks at the top. One tank contains the dilute chamber acid and other the nitrated acid from the base of the Gay-Lussac tower. Both these acids are mixed and then allowed to flow down slowly in Glover's tower. The gases are allowed to enter from the base of the tower. The following four functions occur in this tower:
  - (i) The gases are cooled down from about 400°C to 80°C.
  - (ii) Dilute chamber acid is concentrated.
  - (iii) The nitrated acid from Gay-Lussac tower is denitrated.  $2NO \cdot HSO_4 + H_2O \longrightarrow 2H_2SO_4 + NO + NO_2$
  - (iv) Some SO<sub>2</sub> is converted into H<sub>2</sub>SO<sub>4</sub>.

The sulphuric acid is collected at the bottom of the tower and is about 80%.

(e) Lead chambers: The gaseous mixture  $(SO_2$ , air, oxides of nitrogen) is then allowed to enter three or more large chambers made of lead and supported in wooden frames. Steam is admitted into these chambers from the top when dilute sulphuric acid is formed.

$$SO_2 + NO_2 \longrightarrow SO_3 + NO$$
  
 $SO_3 + H_2O \longrightarrow H_2SO_4$ 

The acid is collected at the bottom of the chambers in a common receiver. This is known as chamber acid and contains 65–70% H<sub>2</sub>SO<sub>4</sub>. It is pumped to the top of Glover's tower for the concentration.

(f) Gay-Lussac tower: The residual gases mainly air and oxides of nitrogen from the lead chambers are allowed to

enter another tower called Gay-Lussac tower. This tower is lined with sheet lead packed with coke. A stream of cold concentrated sulphuric acid pumped from the base of Glover's tower flows down when it absorbs oxides of nitrogen from residual gases.

$$2H_2SO_4 + NO + NO_2 \longrightarrow 2NO \cdot HSO_4 + H_2O$$
Nitrated acid

This acid is pumped on the top of the Glover's tower.

The waste gases are allowed to escape through a chimney on the extreme right of the plant.

**Removal of impurities:** The chief impurities present in the sulphuric acid manufactured by lead chamber process are:

- (i) arsenious oxide (from pyrites).
- (ii) lead sulphate from the action of H<sub>2</sub>SO<sub>4</sub> on lead chamber.
- (iii) oxides of nitrogen.

These are removed as follows:

- (a) The acid is diluted with water when lead sulphate is precipitated which is filtered off.
- (b) Hydrogen sulphide is passed through dilute sulphuric acid which combines with arsenious oxide to form arsenious sulphide.

$$As_2O_3 + 3H_2S \longrightarrow As_2S_3 + 3H_2O$$

Arsenious sulphide is filtered off.

(c) The acid is now distilled over ammonium sulphate when oxides of nitrogen are reduced to nitrogen.

$$(NH_4)_2SO_4 + NO + NO_2 \longrightarrow 2N_2 + 3H_2O + H_2SO_4$$

Usually, the chamber acid is not purified and is used as such for most of the purposes. Whenever pure  $H_2SO_4$  is needed, the acid manufactured by the contact process is used.

Concentration of chamber acid: The acid obtained from Glover's tower contains about 80%  $H_2SO_4$  and is known as brown oil of vitriol (B.O.V.) due to its colour. It can be further concentrated and the concentrated acid is called rectified oil of vitriol (R.O.V.). The concentration is done by evaporation of water present in the acid with the help of hot gases. Two methods are used for this purpose:

- (a) Cascade process and
- (b) Gaillard process.
- (a) Cascade process: A series of ferrosilicon dishes are arranged, one below the other, on a slope. The heating is done by means of hot gases playing below the dishes (Fig. 11.19). As the acid flows downwards, it is subjected to stronger heat, so that when it reaches the lowermost dish it has been concentrated to the maximum. Addition of ammonium sulphate during concentration helps to remove any dissolved oxides of nitrogen.

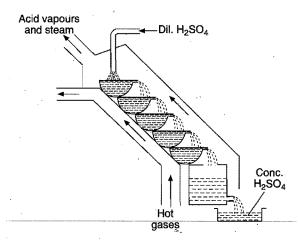

Fig. 11.19

(b) Gaillard process: The dilute acid is allowed to flow down in the form of a spray in a tower lined with acid resisting stone. Hot air enters from the base of the tower. The dilute acid comes in contact with hot air and loses water content. By the time the acid reaches the bottom, it becomes concentrated to about 95% (Fig. 11.20).

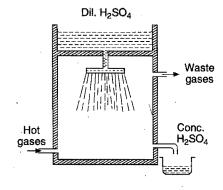

Fig. 11.20

#### **■** (b) Contact Process

**Principle:** This process involves the oxidation of sulphur dioxide by air in the presence of a catalyst.

$$2SO_2 + O_2 \stackrel{Catalyst}{\rightleftharpoons} 2SO_3$$

Sulphur trioxide is dissolved in 98% sulphuric acid when oleum is formed.

$$H_2SO_4 + SO_3 \longrightarrow H_2S_2O_7$$
 (Oleum)

Sulphuric acid of any desired concentration can be obtained from oleum by dilution with water.

$$H_2S_2O_7 + H_2O \longrightarrow 2H_2SO_4$$

The oxidation of sulphur dioxide is reversible and exothermic.

$$2SO_2 + O_2 \rightleftharpoons 2SO_3 + 46.98 \text{ kcal}$$

According to Le-Chatelier principle, the favourable conditions for the greater yield of sulphur trioxide are:

- (a) An excess of air: Best results are obtained when  $SO_2$  and oxygen are present in molecular proportion of 2:3.
- (b) A low temperature: The optimum temperature is  $450^{\circ}$ C. Even at this temperature, the rate of reaction is slow and to accelerate the rate of reaction a catalyst is required. The commonly used catalysts are platinum, ferric oxide or vanadium pentoxide. Out of these, the best yield is obtained by the use of platinum. But it is very expensive and is easily poisoned by impurities. The purification of gases is done carefully when platinum is used as the catalyst. Nowadays, vanadium pentoxide  $(V_2O_5)$  is preferred as it is cheaper and not poisoned by impurities. However, it cannot be recovered after use.
- (c) A higher pressure: The optimum pressure for carrying the oxidation of sulphur dioxide is kept about one atmosphere.

#### Working and Plant

The manufacture of sulphuric acid involves three steps:

- (i) Production of sulphur dioxide
- (ii) Conversion of SO<sub>2</sub> into SO<sub>3</sub>
- (iii) Absorption of SO<sub>3</sub> in H<sub>2</sub>SO<sub>4</sub>

The plant used has been shown diagrammatically in Fig. 11.21.

The various parts of the plant and their functions are described below:

(a) Pyrite burners or sulphur burners: It is a kind of

furnace in which sulphur or iron pyrite is burnt to sulphur dioxide.

$$\begin{array}{c} S + O_2 \longrightarrow SO_2 \\ 4FeS_2 + 11O_2 \longrightarrow 2Fe_2O_3 + 8SO_2 \end{array}$$

The gases leaving the furnace contain SO<sub>2</sub>, air, dust particles and arsenious oxide.

(b) Purification unit: The gases are passed into dust chamber in which heavy dust particles are removed by mechanical precipitation aided by steam or electrically by using the Cottrell precipitator. The gases are now passed through cooling pipes and cooled to 100°C. The gases are led to steam scrubber where these are washed with steam or spray of water. The dust particles and impurities soluble in water are removed. If the catalyst is vanadium pentoxide, the gases should be made completely free from chlorine by using lime water in the scrubber.

The gases are dried by passing through the drying tower-packed with coke or flint stone. A steam of concentrated acid flows down in this tower. Finally, the gases are allowed to arsenic purifier which contains shelves holding ferric hydroxide. Ferric hydroxide absorbs arsenious oxide. The dry and pure mixture of SO<sub>2</sub> and air is then sent to the testing box in order to test the purity of the gas mixture.

(c) Preheater and contact tower: The dry and pure mixture of SO<sub>2</sub> and air is preheated to about 400°C are allowed to enter contact chamber (Fig. 11.22). It consists of iron cylinder containing a number of vertical pipes packed with platinised asbestos heated to about 450°C. SO<sub>2</sub> is oxidised to SO<sub>3</sub> by O<sub>2</sub> of the air. As this conversion is an exothermic reaction, the heat evolved maintains the temperature of the catalyst.

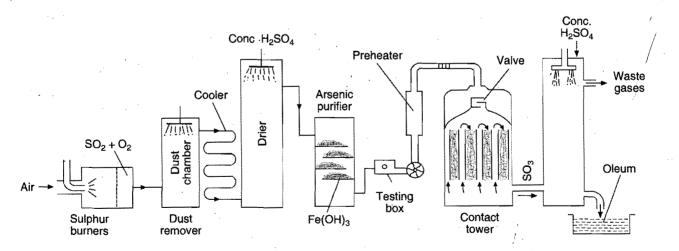

Fig. 11.21

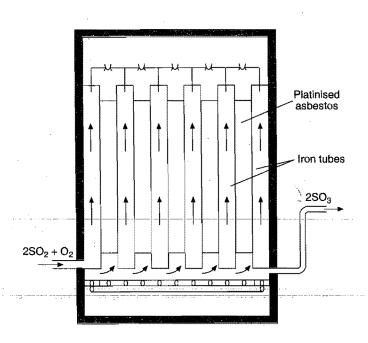

Fig. 11.22 Contact tower

(d) Absorption tower: The  $SO_3$  formed is passed up an absorption tower where it meets a descending stream of conc.  $H_2SO_4$ . The acid absorbs sulphur trioxide forming oleum (fuming sulphuric acid). The  $SO_3$  cannot be absorbed in water because it produces a dense fog which does not easily condense.

## COMPARISON BETWEEN THE LEAD CHAMBER AND CONTACT PROCESSES

	Lead chamber process	Contact process
1.	Catalyst used is a gas—nitric oxide.	Catalyst used is a solid vanadium pentoxide or platinum asbestos.
2.	Acid obtained is impure.	Acid obtained is pure.
3.	Acid obtained is 80%.	Oleum is obtained. Sulphuric acid of any concentration can be obtained from oleum.
4.	Methods of concentration of the acid are troublesome.	Further concentration is not necessary.
5.	It is not necessary to purify the gases.	It is absolutely necessary to purify the gases as impurities act as poison to catalyst.
6.	It is a cheaper method.	This method is costly. The cost has been reduced by the use of V <sub>2</sub> O <sub>5</sub> in place of platinum.

#### **Properties**

**Physical properties:** (a) It is a colourless syrupy liquid. It contains 98.3% sulphuric acid. Its specific gravity is 1.84 at 15°C. It has high viscosity because its molecules are associated due to hydrogen bonding.

- (b) It boils at 338°C (constant boiling mixture containing 98.3% H<sub>2</sub>SO<sub>4</sub> and 1.7% water). It freezes into colourless crystals at 10.5°C.
- (c) It fumes strongly in moist air and is highly corrosive in nature.
  - (d) It is a conductor of heat and electricity.
- (e) It is highly soluble in water. Various hydrates such as H<sub>2</sub>SO<sub>4</sub>·H<sub>2</sub>O, H<sub>2</sub>SO<sub>4</sub>·2H<sub>2</sub>O, H<sub>2</sub>SO<sub>4</sub>·3H<sub>2</sub>O, H<sub>2</sub>SO<sub>4</sub>·4H<sub>2</sub>O, are known. Heat is evolved when dissolved in water, usually bumping occurs. Due to this reason water should not be added to concentrated sulphuric acid for dilution but concentrated sulphuric acid should be added slowly to cold water with constant stirring. Due to its great affinity for water, it is used as a dehydrating substance.

#### Chemical properties:

(a) **Dissociation:** At 444°C, the vapours of sulphuric acid dissociate into steam and sulphur trioxide,

$$H_2SO_4 \Longrightarrow H_2O + SO_3$$

**(b) Acidic nature:** Dilute sulphuric acid is a strong dibasic acid. It ionises as:

$$H_2SO_4 \Longrightarrow H^+ + HSO_4^- \Longrightarrow 2H^+ + SO_4^{2-}$$

(i) It forms two series of salts with bases.

$$\begin{array}{c} \text{NaOH} + \text{H}_2\text{SO}_4 \longrightarrow \text{NaHSO}_4 + \text{H}_2\text{O}; \\ & \text{Sodium} \\ \text{bisulphate} \\ \\ 2\text{NaOH} + \text{H}_2\text{SO}_4 \longrightarrow \text{Na}_2\text{SO}_4 + 2\text{H}_2\text{O} \\ & \text{Sodium} \\ \text{sulphate} \\ \end{array}$$

(ii) It decomposes carbonates and bicarbonates into carbon dioxide.

$$Na_2CO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O + CO_2$$
  
 $NaHCO_3 + H_2SO_4 \longrightarrow NaHSO_4 + H_2O + CO_2$ 

(iii) It reacts with electropositive metals evolving hydrogen.

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$$
  
Fe +  $H_2SO_4 \longrightarrow FeSO_4 + H_2$ 

(iv) It displaces more volatile acids from their metal salts.

$$\begin{split} 2NaCl &+ H_2SO_4 \longrightarrow Na_2SO_4 + 2HCl \\ Ca_3(PO_4)_2 &+ 3H_2SO_4 \longrightarrow 3CaSO_4 + 2H_3PO_4 \\ CaC_2O_4 &+ H_2SO_4 \longrightarrow CaSO_4 + H_2C_2O_4 \\ Calcium oxalate & Oxalic acid \end{split}$$

$$FeS + H_2SO_4 \longrightarrow FeSO_4 + H_2S$$

$$2CH_3COONa + H_2SO_4 \longrightarrow Na_2SO_4 + 2CH_3COOH$$

$$2NaNO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + 2HNO_3$$

$$CaF_2 + H_2SO_4 \longrightarrow CaSO_4 + 2HF$$

or.

$$2NaNO_2 + H_2SO_4 \longrightarrow Na_2SO_4 + 2HNO_2$$

$$\downarrow$$
 $NO + NO_2 + H_2O$ 

(c) Oxidising nature: It acts as a strong oxidising agent. The potential equation is:

$$\begin{array}{c} \text{H}_2\text{SO}_4 \longrightarrow \text{H}_2\text{O} + \text{SO}_2 + \text{O} \\ \text{(Hot conc.)} \\ \text{2H}_2\text{SO}_4 + 2e^- \longrightarrow \text{SO}_4^{2-} + 2\text{H}_2\text{O} + \text{SO}_2 \end{array}$$

(i) Non-metals such as carbon and sulphur are oxidised to their oxides.

$$[H_2SO_4 \longrightarrow H_2O + SO_2 + O] \times 2$$

$$C + 2O \longrightarrow CO_2$$

$$C + 2H_2SO_4 \longrightarrow CO_2 + 2SO_2 + 2H_2O$$

$$[H_2SO_4 \longrightarrow H_2O + SO_2 + O] \times 2$$

$$S + 2O \longrightarrow SO_2$$

$$S + 2H_2SO_4 \longrightarrow 3SO_2 + 2H_2O$$

Phosphorus is oxidised to orthophosphoric acid.

$$[H_2SO_4 \longrightarrow H_2O + SO_2 + O] \times 5$$

$$2P + 5O \longrightarrow P_2O_5$$

$$P_2O_5 + 3H_2O \longrightarrow 2H_3PO_4$$

$$2P + 5H_2SO_4 \longrightarrow 2H_3PO_4 + 5SO_2$$

(ii) Metals like copper, silver, mercury, etc., are first oxidised by conc.  $H_2SO_4$  and then the oxides combine with acid to form corresponding sulphates.

$$\begin{array}{c} H_2SO_4 \longrightarrow H_2O + SO_2 + O \\ Cu + O \longrightarrow CuO \\ \hline CuO + H_2SO_4 \longrightarrow CuSO_4 + H_2O \\ \hline Cu + 2H_2SO_4 \longrightarrow CuSO_4 + SO_2 + 2H_2O \\ \hline 2Ag + 2H_2SO_4 \longrightarrow Ag_2SO_4 + SO_2 + 2H_2O \\ Hg + 2H_2SO_4 \longrightarrow HgSO_4 + SO_2 + 2H_2O \\ \end{array}$$

(iii) Iodine is liberated from KI (HI is oxidised to I<sub>2</sub>)

$$2KI + H2SO4 \longrightarrow K2SO4 + 2HI$$

$$H2SO4 \longrightarrow H2O + SO2 + O$$

$$2HI + O \longrightarrow H2O + I2$$

$$2KI + 2H2SO4 \longrightarrow K2SO4 + SO2 + I2 + 2H2O$$

Similarly, bromine is liberated from KBr (HBr is oxidised to Br<sub>2</sub>).

$$2KBr + 2H_2SO_4 \longrightarrow K_2SO_4 + SO_2 + Br_2 + 2H_2O$$

(iv) In presence of Hg as a catalyst, naphthalene is oxidised to phthalic acid.

$$C_{10}H_8 + 9H_2SO_4 \longrightarrow C_8H_6O_4 + 10H_2O + 9SO_2 + 2CO_2$$
Phthalic acid

(d) Dehydrating nature: As sulphuric acid has great affinity for water, it acts as a powerful dehydrating agent. Its

corrosive action on skin is also due to dehydration of skin. It absorbs water from organic compounds.

$$\begin{array}{c} C_{12}H_{22}O_{11} \xrightarrow{H_2SO_4} 12C \\ C_{ane \ sugar} \xrightarrow{(-11H_2O)} 12C \\ C_6H_{12}O_6 \xrightarrow{H_2SO_4} 6C \\ Glucose \xrightarrow{(-6H_2O)} 6C \\ (COOH)_2 \xrightarrow{(-H_2O)} CO + CO_2 \\ Oxalic \ acid \xrightarrow{(-H_2O)} CO \\ Formic \ acid \xrightarrow{(-H_2O)} CO \\ Ethyl \ alcohol \xrightarrow{(-H_2O)} C_2H_5OC_2H_5 \\ \hline Ethyl \ alcohol \ Ether \\ \end{array}$$

Cloth, wood, starch, paper, etc., are all charred in concentrated sulphuric acid.

#### (e) Miscellaneous reactions:

(i) **Sulphonation**: Aromatic compounds react with sulphuric acid forming sulphonic acids.

$$\begin{array}{c} C_6H_6 + H_2SO_4 & \longrightarrow C_6H_5SO_3H + H_2O \\ \text{Benzene} & \text{Benzene} \\ \text{sulphonic acid} \end{array}$$

(ii) Action of PCl<sub>5</sub>: The molecule of sulphuric acid contains two hydroxyl groups. One or both the hydroxyl groups can be replaced by chlorine when treated with PCl<sub>5</sub>.

OH 
$$O_2S$$
  $OH + PCl_5 \longrightarrow O_2S$   $OH + PCl_3 + HCl$   $OH + PCl_5 \longrightarrow O_2S$   $OH + PCl_5 \longrightarrow OH$   $O$ 

(iii) On heating potassium ferrocyanide with concentrated sulphuric acid, carbon monoxide is evolved.

$$K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O \longrightarrow$$
  
 $2K_2SO_4 + FeSO_4 + 3(NH_4)_2SO_4 + 6CO$ 

(iv) On heating potassium chlorate with concentrated sulphuric acid, chlorine dioxide is evolved with explosion.

$$3KClO_3 + 3H_2SO_4 \longrightarrow 3KHSO_4 + HClO_4 + 2ClO_2 + H_2O$$

(v) Sulphuric acid reacts with barium and lead salts to form insoluble sulphates. These sulphates are even insoluble in conc. HCl and conc. HNO<sub>3</sub>.

$$BaCl_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HCl$$
  
 $Pb(NO_3)_2 + H_2SO_4 \longrightarrow PbSO_4 + 2HNO_3$ 

(vi)  $H_2SO_4$  absorbs sulphur trioxide forming oleum or fuming sulphuric acid.

$$H_2SO_4 + SO_3 \longrightarrow H_2S_2O_7$$
Oleum

(vii) H<sub>2</sub>SO<sub>4</sub> when treated with phosphorus pentoxide loses water and forms sulphur trioxide.

$$H_2SO_4 + P_2O_5 \longrightarrow 2HPO_3 + SO_3$$

### Uses

It is used:

- (i) for the manufacture of fertilizers such as ammonium sulphate and superphosphate of lime.
- (ii) in the manufacture of other acids such as hydrochloric acid, orthophosphoric acid, nitric acid, etc.
- (iii) in the manufacture of explosives such as, nitroglycerine, gun cotton, TNT (trinitro-toluene), picric acid, etc.
- (iv) in the manufacture of important chemicals such as sodium carbonate, alums, metal sulphates, ethers, phosphorus, etc.
  - (v) in the refining of petroleum.
- (vi) in the manufacture of coal-tar dyes and a number of drugs and disinfectants.
  - (vii) in the textile, paper and dyeing industries.
  - (viii) in the leather industry for tanning.
- (ix) for cleansing metals before electroplating, enameling, galvanising, etc., (Pickling).
  - (x) in storage batteries.
  - (xi) in manufacturing paints and pigments.
- (xii) as an important laboratory reagent. In organic chemistry it is used for synthesis of various organic compounds and sulphonation reactions. It is also used as an oxidising and a dehydrating agent.

**Structure:** Sulphuric acid has two OH groups which are directly attached to sulphur. The molecule has been assigned the following structure:

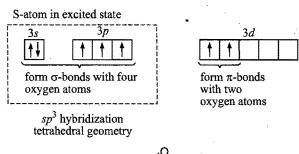

The sulphate ion,  $SO_4^{2-}$ , is therefore, represented as

$$\begin{bmatrix} O \\ \uparrow \\ O - S - O \\ \downarrow \\ O \end{bmatrix}^{2-}$$

However, the ion shows a considerable amount of double character as the bond lengths are all rather short. Thus, the sulphate ion is a resonance hybrid, as represented below:

The unionised acid is, therefore, resonance hybrid of the following two structures:

In crystals,  $SO_4^{2-}$  ion has a tetrahedral structure. This can be explained on the basis of  $sp^3$  hybridization.

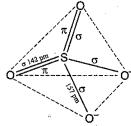

Fig.11.23 Tetrahedral geometry of SO<sub>4</sub><sup>2-</sup> ion

### Tests for H<sub>2</sub>SO<sub>4</sub>:

- (1) When heated with copper, it evolves  $SO_2$  which has a characteristic smell. The gas reacts with acidified  $K_2Cr_2O_7$  solution which is turned green.
- (2) It forms white precipitate with barium chloride solution which is insoluble in conc. HCl and conc. HNO<sub>3</sub>.
- (3) When heated with NaCl, it evolves HCl which forms white fumes with NH<sub>4</sub>OH.

## SOME SOLVED PROBLEMS

**Example 1.** A is a binary compound of univalent metal. 1.422 g of A reacts completely with 0.321 g of sulphur in an evacuated and sealed tube to give 1.743 g of a white crystalline solid, B, that forms a hydrated double salt, C, with  $Al_2(SO_4)_3$ . Identify A, B and C. [1.1.T.1994]

### **Solution:**

As the solid B forms a hydrated double salt with  $Al_2(SO_4)_3$ , it should be a sulphate of a univalent metal,  $M_2SO_4$ .

One molecule of sulphate contains one sulphur atom, *i.e.*, the mass of the sulphate which contains 32.1 g sulphur should be its molecular mass.

0.321 g sulphur is present in (1.422 + 0.321 = 1.743 g) of B.

32.1 g of sulphur is present in 
$$=\frac{1.743}{0.321} \times 32.1 = 174.3$$
 g

Let the atomic mass of univalent metal be x.

$$M_2SO_4 = 2x + 32.1 + 64.0 = 174.3$$
or
$$2x = 78.2$$

$$x = 39.1$$

Atomic mass 39.1 corresponds to potassium.

Thus, the compound B is  $K_2SO_4$  and the compound C is  $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$ .

Since, B is formed with interaction of A and sulphur, A must be an oxide of potassium (most probably  $KO_2$ ).

$$2KO_2 + S_{2 \times 71.1} \xrightarrow{32.1} K_2SO_4$$

32.1 g of S reacts with  $A = 2 \times 71.1$  g

0.321 g of S reacts with 
$$A = \frac{2 \times 71.1}{32.1} \times 0.321 = 1.422$$
 g

Thus, A is supported by the given data.

A is, therefore, potassium superoxide,  $KO_2$ .

**Example 2.** When gas A is passed through dry KOH at low temperature, a deep red coloured compound, B and a gas C are obtained. The gas A, on reaction with but-2-ene, followed by treatment with  $Zn/H_2O$  yields acetaldehyde. Identify A, B and C. [LI.T. 1994]

### Solution:

The reaction of gas A with but-2-ene followed by treatment with  $Zn/H_2O$  suggests that A is  $O_3$ .

Reaction with KOH
$$2\text{KOH} + 5\text{O}_3 \longrightarrow 2\text{KO}_3 + 5\text{O}_2 + \text{H}_2\text{O}$$

$$(A) \qquad (B) \qquad (C)$$
(Deep red coloured)

**Example 3.** How you will obtain the following from sulphuric acid?

(i)  $SO_2$  (ii)  $SO_3$  (iii)  $SO_2Cl_2$  (iv)  $H_2S$  (v) S.

### Solution:

(i)  $SO_2$  is obtained by heating copper with conc.  $H_2SO_4$ — $Cu + 2H_2SO_4 \longrightarrow CuSO_4 + SO_2 + 2H_2O$ It can also be obtained by boiling sulphur with conc.  $H_2SO_4$ .

$$S + 2H_2SO_4 \longrightarrow 3SO_2 + 2H_2O$$

(ii) H<sub>2</sub>SO<sub>4</sub> when treated with P<sub>2</sub>O<sub>5</sub> loses water and forms SO<sub>3</sub>.

$$H_2SO_4 + P_2O_5 \longrightarrow 2HPO_3 + SO_3$$

(iii) SO<sub>2</sub>Cl<sub>2</sub> is formed when conc. H<sub>2</sub>SO<sub>4</sub> is treated with excess of PCl<sub>5</sub>.

$$H_2SO_4 + 2PCl_5 \longrightarrow SO_2Cl_2 + 2POCl_3 + 2HCl$$

(iv) and (v) H<sub>2</sub>S and S are obtained from conc. H<sub>2</sub>SO<sub>4</sub> by the following reactions.

$$BaCl_2 + H_2SO_4 \rightarrow BaSO_4 \xrightarrow{4C} BaS \xrightarrow{HCl} H_2S \xrightarrow{Oxid.} S$$

### Example 4. Explain the following:

- (i) An acidified  $K_2Cr_2O_7$  paper turns green when exposed to  $SO_2$ .
- (ii)  $H_2S$  acts only as reducing agent while  $SO_2$  can act both as a reducing agent and an oxidising agent.
  - (iii) SO2 acts as a bleaching agent.
  - (iv) Sugar turns black on addition of conc. H<sub>2</sub>SO<sub>4</sub>.
  - (v) Ozone destroys mercury meniscus.
  - (vi) SF<sub>6</sub> is known but SH<sub>6</sub> is not known.

### **Solution:**

(i) Acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> acts as an oxidising agent in presence of SO<sub>2</sub> and converted into chromium compound which is green in colour.

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3O_3SO_2 + 3O_4 + 3H_2O \longrightarrow 3H_2SO_4$$

$$\overline{\text{K}_2\text{Cr}_2\text{O}_7}$$
 +  $\overline{\text{H}_2\text{SO}_4}$  +  $\overline{\text{3SO}_2}$   $\longrightarrow$   $\overline{\text{K}_2\text{SO}_4}$  +  $\overline{\text{Cr}_2(\text{SO}_4)_3}$  +  $\overline{\text{H}_2\text{O}}$ 

(ii) On the basis of electronic configuration  $(3s^23p^4)$ , the maximum and minimum oxidation states of S are +6 and -2.

In  $H_2S$ , the oxidation state of S is -2. It can increase only oxidation state and cannot decrease. Thus,  $H_2S$  can act only as a reducing agent. In  $SO_2$ , the oxidation state is +4, *i.e.*, it can be increased as well as decreased. Thus,  $SO_2$  can act both as a reducing agent and an oxidising agent.

(iii)  $SO_2$  in presence of moisture is oxidised to  $H_2SO_4$  liberating nascent hydrogen. The nascent hydrogen bleaches the coloured substance.

$$SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2[H]$$

Coloured substance  $+ 2[H] \longrightarrow Colourless$ 

(iv) Conc. H<sub>2</sub>SO<sub>4</sub> has great affinity for water molecules, *i.e.*, it acts as a dehydrating agent. When in contact with sugar, all water molecules are taken up and carbon is left behind.

$$C_{12}H_{22}O_{11} \xrightarrow{Conc. H_2SO_4} 12C + 11H_2O$$

(v) Ozone acts as a strong oxidising agent. It oxidises mercury into mercurous oxide which starts sticking to glass. Mercury loses its mobility, *i.e.*, mercury meniscus is destroyed.

$$2Hg + O_3 \longrightarrow Hg_2O + O_2$$

(vi) In the highest oxidation state, sulphur can combine only with highly electronegative element like fluorine and not hydrogen. Hence, sulphur forms SF<sub>6</sub> but not SH<sub>6</sub>.

**Example 5.** State with balanced equation what happens when?

- (a) Potassium ferrocyanide is heated with conc.  $H_2SO_4$ .
- (b) A mixture of potassium chlorate, oxalic acid and sulphuric acid is heated.
  - (c) Sodium chlorate reacts with sulphur dioxide.
- (d) Chlorine gas is passed into water saturated with hydrogen sulphide. [M.L.N.R. 1991]
- (e) Hydrogen sulphide is passed through sodium bisulphite solution. [I.J.T. 1991]

### **Solution:**

(a) CO is evolved.

$$K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O \longrightarrow$$
  
 $2K_2SO_4 + FeSO_4 + 3(NH_4)_2SO_4 + 6CO$ 

(b) Potassium chlorate is reduced while oxalic acid is oxidised.

$$KClO_3 + H_2SO_4 \longrightarrow KHSO_4 + HCl + 3O$$
  
 $3H_2C_2O_4 + 3O \longrightarrow 6CO_2 + 3H_2O$ 

$$KClO_3 + 3H_2C_2O_4 + H_2SO_4 \longrightarrow KHSO_4 + HCl + 6CO_2 + 3H_2O_4$$

(c) NaClO<sub>3</sub> is reduced to NaCl.

$$[SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2H] \times 3$$
  
NaClO<sub>3</sub> + 6H  $\longrightarrow$  NaCl + 3H<sub>2</sub>O

$$NaClO_3 + 3SO_2 + 3H_2O \longrightarrow 3H_2SO_4 + NaCl$$

(d) 
$$Cl_2 + H_2S \longrightarrow 2HCl + S$$

(e) 
$$2NaHSO_3 \longrightarrow Na_2SO_3 + H_2O + SO_2$$
$$SO_2 + 2H_2S \longrightarrow 2H_2O + 3S$$
$$2NaHSO_3 + 2H_2S \longrightarrow Na_2SO_3 + 3S + 3H_2O$$

**Example 6.** Sulphur melts to form a clear mobile liquid at 119°C but on further heating to 180°C, it becomes viscous. Why?

### Solution:

Upto 119°C, sulphur exists as S<sub>8</sub> molecules which can roll over one another to form a mobile liquid. However, when this liquid is further heated to 180°C, the cleavage of ring structure occurs and zig-zag open chains are formed which get interwound and tangled together and hence sulphur becomes more viscous.

**Example 7.** SOCl<sub>2</sub> can act as a weak Lewis acid as well as a weak Lewis base. Explain.

### Solution:

Like nitrogen in ammonia, sulphur has a lone pair of electrons which it can donate, hence it acts as a weak base.

 $SOCl_2$  has also empty *d*-orbitals which can accommodate electron pairs from bases and hence acts as a weak acid.

**Example 8.** (a) Which form of sulphur does show paramagnetic nature? Explain.

- (b) Compounds of fluorine and oxygen are called fluorides and not oxides. Explain.
- (c) Sulphur disappears when boiled with an aqueous solution of sodium sulphite. Why?

### **Solution:**

- (a) In vapour state, sulphur partly exists as  $S_2$  molecules and  $S_2$  molecule like  $O_2$  molecule has two unpaired electrons in the antibonding  $\pi$ -orbitals and exhibits paramagnetic nature.
- (b) This is because of higher electronegativity of fluorine than oxygen. In naming a compound, the electropositive or less electronegative element is taken first, thus, the compounds of fluorine and oxygen are called oxygen fluorides and fluorine oxides.
- (c) Sulphur combines with sodium sulphite and forms sodium thiosulphate which is soluble in water and hence S disappears.

**Example 9.** Knowing the electron gain enthalpy values for  $O \longrightarrow O^-$  and  $O \longrightarrow O^{2-}$  as  $-141 \text{ kJ mol}^{-1}$  and  $702 \text{ kJ mol}^{-1}$  respectively, how can you account for the formation of a large number of oxides having  $O^{2-}$  species and not  $O^-$ ?

### Solution:

Although the formation of  $O^{2-}$  anion requires more energy in comparison to the formation of  $O^{-}$  anion factually energy is released), yet in large number of oxides, oxygen is divalent in nature. This is due to the fact that lattice energies of the oxides having  $O^{2-}$  anions are very high on account of greater magnitude of electrostatic forces of attraction.

**Example 10.** Give at least one example to explain the following properties:

- (i) Sulphuric acid is a dibasic acid.
- (ii) Sulphuric acid is a dehydrating agent.
- (iii) Sulphuric acid is an oxidising agent.

### Solution:

(i) H<sub>2</sub>SO<sub>4</sub> forms two series of salts, *i.e.*, both the hydrogen atoms are replaceable.

$$H_2SO_4 \longrightarrow H^+ + HSO_4^- \longrightarrow 2H^+ + SO_4^{2-}$$
 $H_2SO_4 + NaOH \longrightarrow NaHSO_4 + H_2O$ 
Sodium hydrogen
Sulphate (acid salt)

$$H_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2H_2O$$
Sodium sulphate
(Normal salt)

(ii) H<sub>2</sub>SO<sub>4</sub> has great affinity for water molecules and hence, acts as a dehydrating agent.

$$\text{HCOOH} \xrightarrow{\text{Conc. H}_2\text{SO}_4} \text{H}_2\text{O} + \text{CO}$$

(iii) H<sub>2</sub>SO<sub>4</sub> oxidises metals, nonmetals and other compounds.

Cu + 
$$2H_2SO_4(conc.) \longrightarrow CuSO_4 + SO_2 + 2H_2O$$
  
 $S + 2H_2SO_4 \longrightarrow 3SO_2 + 2H_2O$   
 $2HI + H_2SO_4 \longrightarrow I_2 + SO_2 + 2H_2O$ 

# SUMMARY AND IMPORTANT POINTS TO REMEMBER

- 1. Group 16 or VIA of the periodic table consists of six elements—oxygen, sulphur, selenium, tellurium, polonium and ununhexium. These elements are called **chalcogens**, *i.e.*, ore forming elements. These are *p*-block elements as the last differentiating electron is accommodated on *np* shell. All have six electrons in their outermost shell, *i.e.*, *ns*<sup>2</sup>*np*<sup>4</sup> configuration.
- 2. The elements oxygen and sulphur are common while selenium, tellurium and polonium are comparatively rare. Oxygen is the most abundant element. It makes up 46.6% by mass of the earth's crust. It is found both in free and combined state. Sulphur is the sixteenth most abundant element. It occurs mainly in the combined form. The last member is radioactive in nature.
- 3. Oxygen is a gas while other members of group 16 are solids. Oxygen is a diatomic molecule while the molecules of other members are complex. Sulphur, selenium and tellurium exist as 8-atom staggered rings. In S<sub>8</sub> molecule, each S-atom is sp<sup>3</sup> hybridized involving both bonding and non-bonding electron pairs.

Oxygen atom is capable to form multiple bonds ( $p\pi$ - $p\pi$  interaction) with other oxygen atom on account of small size. However, this tendency is missing in sulphur atom. The bond energy of oxygen-oxygen double bond is quite high as compared to oxygen-oxygen single bond. In sulphur, the sulphur-sulphur double bond energy is not so large in comparison to single bond energy. As a result -O-O-O—chains are less stable as compared to O=O molecule while -S-S-S—chains are more stable than S=S molecule. Thus, oxygen exists as a diatomic gas molecule, sulphur exists as  $S_8$  solid.

The diatomic molecule O=O accounts for high dissociation energy but does not explain paramagnetic nature. Pauling proposed 3-electron bond structure :O:•••O: to explain paramagnetic behaviour.

4. (a) Metallic character increases with increase in atomic number.

- (b) Atomic radii, atomic volume and density increase gradually from O to Po.
- (c) Electronegativity decreases gradually. Oxygen is second most electronegative element.
- (d) The melting and boiling points increase gradually from O to Po.
- (e) The ionisation potential values are high and decrease gradually. The elements do not lose the electrons to form positive ions easily.
- (f) All the members show allotropy. Oxygen: Ordinary oxygen and ozone are allotropic forms. Sulphur: Rhombic, monoclinic, plastic and amorphous are allotropic forms.
- Selenium: Red form and grey form are allotropic forms.

  (g) Oxygen and sulphur show the property of catenation but this property is more pronounced in sulphur.
- 5. All these elements have six electrons in their valency shell. They complete the octet either (a) by forming bivalent anion gaining two electrons such as:

 $O^{2-}$ ,  $S^{2-}$ ,  $Se^{2-}$  and  $Te^{2-}$  showing electrovalency (di). or (b) by forming two covalent bonds, *i.e.*, sharing two electrons.

Po does not form  $Po^{2-}$  anion. However, it forms  $Po^{2+}$  ions. Oxygen shows -2 oxidation state in its compounds except in oxygen fluorides. The tendency to show -2 oxidation state decreases as we go down in the group. However, positive oxidation states are exhibited by S, Se, Te and Po. In addition to +2 oxidation state +4 and +6 oxidation states are observed. This is due to availability of d-orbitals in these elements.

The compounds having +4 oxidation state show both oxidising and reducing properties while compounds having +6 oxidation state are only oxidising.

- All the elements of group 16 form hydrides of the type H<sub>2</sub>M. H<sub>2</sub>O, H<sub>2</sub>S, H<sub>2</sub>Se, H<sub>2</sub>Te and H<sub>2</sub>Po.
  - (a) H<sub>2</sub>O is a liquid while other hydrides are colourless poisonous gases with bad odours. H<sub>2</sub>O (water) has low volatility (high boiling point) as hydrogen bonding is

- present. H<sub>2</sub>S has high volatility as no hydrogen bonding is present. Volatility decreases from H<sub>2</sub>S to H<sub>2</sub>Te due to increase in molecular masses.
- (b) As the electronegativity difference between M and H decreases, the covalent character increases from H<sub>2</sub>O to H<sub>2</sub>Te. Water is highly polar. It has high dielectric constant.
- (c) Thermal stability decreases. This is due to an increase in M—H bond length. Water dissociates at 2000°C while  $H_2$ Te decomposes at room temperature.
- (d) Acidic nature increases from H<sub>2</sub>O to H<sub>2</sub>Te.
- (e) Except H<sub>2</sub>O, other hydrides are reducing agents.
- (f) Hydrides of S, Se, Te and Po burn in oxygen with blue flame forming dioxides.
- (g) All these hydrides are V-shaped. The central atom is  $sp^3$  hybridized. The bond angles are 104.5°, 92.5°, 91° and 90° in H<sub>2</sub>O, H<sub>2</sub>S, H<sub>2</sub>Se and H<sub>2</sub>Te.
- 7. S, Se, Te and Po form oxides on burning in air of the type  $MO_2$ , e.g.,  $SO_2$ ,  $SEO_2$ ,  $TEO_2$  and  $POO_2$ .

The acidic and stability of these oxides decrease down the group.  $SO_2$  and  $SeO_2$  are acidic while  $TeO_2$  and  $PoO_2$  are amphoteric.  $SO_2$  is a gas,  $SeO_2$  is a volatile solid while  $TeO_2$  and  $PoO_2$  are crystalline solids.  $SO_2$  is an angular molecule with bond angle 119.5°. S is in  $sp^2$  hybridized state. The bond length is 143 Å.

$$p\pi - d\pi$$
 bond  $p\pi - p\pi$  bond  $p\pi - p\pi$  bond

- S, Se and Te also form trioxides. The trioxides are acidic in nature. The acidic nature decreases from SO<sub>3</sub> to TeO<sub>3</sub>.
- 8. Sulphur, selenium and tellurium form similar oxyacids.

H <sub>2</sub> SO <sub>3</sub> Sulphurous acid Salts: Sulphites	H <sub>2</sub> SeO <sub>3</sub> Selenous acid Selenites	H <sub>2</sub> TeO <sub>3</sub> Tellurous acid Tellurites	increases
H <sub>2</sub> SO <sub>4</sub> Sulphuric acid Salts: Sulphates	H <sub>2</sub> SeO <sub>4</sub> Selenic acid Selenates	H <sub>2</sub> TeO <sub>4</sub> Telluric acid Tellurates	Strength in

Strength increases

9. S, Se and Te form hexafluorides of type MF<sub>6</sub>. They all involve sp<sup>3</sup>d<sup>2</sup> hybridization, i.e., possess octahedral structure. These are colourless gases. SF<sub>6</sub> is extremely inert. SeF<sub>6</sub> is slightly reactive while TeF<sub>6</sub> is hydrolysed by water into H<sub>6</sub>TeO<sub>6</sub>. Many tetrahalides are known. SF<sub>4</sub> is a gas, SeF<sub>4</sub> is a liquid while TeF<sub>4</sub> is a solid. S, Se, Te and Po form tetrachlorides and bromides while Te and Po form tetraiodides. All tetrahalides posses trigonal bipyramid structure with sp<sup>3</sup>d hybridization. One position is occupied by lone pair and four by halogen atoms.

All elements except Se form stable dichlorides and dibromides. Dihalides form tetrahedral molecules due to  $sp^3$  hybridization. Dimeric monohalides as  $S_2F_2$ ,  $S_2Cl_2$  and  $S_2Br_2$  are known. Their structures are similar to  $H_2O_2$ .

10. Only S and Se form oxyhalides. They are called thionyl and selenyl halides.

SOF<sub>2</sub> SOCl<sub>2</sub> SOBr<sub>2</sub> SeOF<sub>2</sub> SeOCl<sub>2</sub> SeOBr<sub>2</sub>

They react with water readily.

In addition, sulphuryl halides are also known,  $SO_2X_2$ . These may be regarded as derivatives of  $H_2SO_4$  where both the OH groups have been replaced by halogen atoms.

11. Lavoisier regarded oxygen as an essential constituent of all acids named it so (oxus = acid and gennas = maker). It occurs in the atmosphere to the extent of 21% by volume and 23% by mass. This percentage remains constant by the process of photosynthesis. It is an essential ingredient in all living matter and is of great importance in respiration and combustion.

It is a colourless, odourless and tasteless gas. It is little heavier than air and slightly soluble in water. It is paramagnetic in nature. There are three isotopes of oxygen with mass numbers 16, 17 and 18. Oxygen is not combustible but it helps in combustion. It is very active element. It directly combines with almost all metals (except noble metals) and non-metals (except zero group elements and halogens) and reacts with large number of compounds. The reactions are usually exothermic.

- 12. Oxygen combines nearly with all the elements except inert gases, noble metals and halogens. The binary compounds of oxygen with other elements are called oxides. However, the compounds of oxygen and fluorine are termed fluorides as fluorine is more electronegative than oxygen. The oxides can be classified, on the basis of chemical behaviour, into:
  - (a) Acidic oxides: The oxides which dissolve in water to form oxoacids are called acidic oxides or acid anhydrides. These react with bases and form salts. They also combine with basic oxides. These oxides are generally formed by non-metals. Examples are: CO<sub>2</sub>, B<sub>2</sub>O<sub>3</sub>, SiO<sub>2</sub>, NO<sub>2</sub>, P<sub>2</sub>O<sub>5</sub>, N<sub>2</sub>O<sub>5</sub>, SO<sub>2</sub>, Cl<sub>2</sub>O<sub>7</sub>, etc. Some metals in higher oxidation states also form acidic oxides such as V<sub>2</sub>O<sub>5</sub>, CrO<sub>3</sub>, Mn<sub>2</sub>O<sub>7</sub>, etc. Some of the oxides form two oxyacids. These are called mixed oxides such as NO<sub>2</sub>, P<sub>4</sub>O<sub>3</sub>, etc.
  - (b) Basic oxides: The oxides which either dissolve in water to form alkalies or combine with acids to form salts or combine with acidic oxides are called basic oxides. The examples are Na<sub>2</sub>O, CaO, CuO, PbO, FeO, etc.
  - (c) Neutral oxides: The oxides which neither combine with acids nor combine with bases to form salts.

    Examples are: CO, N<sub>2</sub>O, H<sub>2</sub>O, NO, etc.
  - (d) Amphoteric oxides: The oxides which react with acids and bases both are termed amphoteric. Examples are: ZnO, PbO, SnO, SnO<sub>2</sub>, PbO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub>, BeO, Cr<sub>2</sub>O<sub>3</sub>, etc.

Oxides are also classified on the basis of oxygen content.

- (a) Normal oxides: These contain oxygen just as much as permitted by usual valence rules.
- **(b) Polyoxides:** These contain more oxygen than permitted by usual valence rules.

- (i) **Peroxides:** These on treatment evolve H<sub>2</sub>O<sub>2</sub> with dilute acids such as Na<sub>2</sub>O<sub>2</sub>, BaO<sub>2</sub>, etc.
- (ii) Superoxides: Such as MnO<sub>2</sub>, Mn<sub>2</sub>O<sub>7</sub>, KO<sub>2</sub>, RbO<sub>2</sub>, etc.
- (c) Suboxides: These contain less oxygen permitted by usual valency rules such as N<sub>2</sub>O, CO, etc.
- (d) Mixed oxides: These are made up of two similar oxides such as Pb<sub>3</sub>O<sub>4</sub> (2PbO + PbO<sub>2</sub>), Fe<sub>3</sub>O<sub>4</sub> (Fe<sub>2</sub>O<sub>3</sub> + FeO), Mn<sub>3</sub>O<sub>4</sub> (2MnO + MnO<sub>2</sub>).
- 13. In 1840, Schonbien observed that rotten smell during passing of electric discharge through air was due to formation of a new gas which he named ozone (ozo = I smell). Sorret established its formula, O<sub>3</sub> and attributed that ozone is an allotrope of oxygen.

Ozone is present in sufficient amounts in the atmosphere at higher altitudes, *i.e.*, 12 to 15 miles above earth's surface. It is formed there by action of ultraviolet rays of the sun. Near earth's surface ozone is decomposed by dust particles.

It is obtained by passing silent electric discharge through dry oxygen. The apparatus used for this purpose is called **ozoniser**. The commonly used ozonisers are (i) Siemen's ozoniser and (ii) Brodie's ozoniser. The mixture obtained from ozoniser consists of 5–10% ozone by volume and the mixture is called **ozonised oxygen**. The ozonised oxygen is cooled by liquid air when liquid oxygen is obtained.

Fluorine reacts with water at low temperature when mixture of ozonised oxygen is formed.

14. Ozone is a pale blue gas with a characteristic strong smell. It can be liquefied to pale blue liquid at -112.4°C. It is heavier than air. It is slightly soluble in water but more soluble in turpentine oil, glacial acetic acid or carbon tetrachloride. It causes headache and nausea.

It is unstable and decomposes completely into oxygen at  $300^{\circ}$ C. It acts as a powerful oxidising agent. The potential equation is :  $O_3 \longrightarrow O_2 + O$ . The oxidation potential is + 2.07 V. It is a good bleaching agent. The bleaching action is due to its oxidising nature. It bleaches oil, ivory, flour, starch, waxes, pulp, etc.

It reacts with unsaturated organic compounds containing double bonds forming **ozonides**. The ozonides break with water to form carbonyl compounds. The process is known as **ozonolysis**. Mercury is oxidised by ozone to suboxide (Hg<sub>2</sub>O) which dissolve in mercury. It starts sticking to glass and loses mobility. The mercury loses its meniscus. This is termed as the **tailing of mercury**. Ozone molecule is V-shaped with a bond angle 116.8° and O—O bond length 1.278 Å.

- 15. The name sulphur has been derived from sanskrit word sulveri meaning killer of copper. It is widely distributed in nature both in free and combined state. The free sulphur is found in volcanic regions of the world. The underground sulphur is extracted by Frasch process.
- **16.** Organic compounds of plant and animal origin, *e.g.*, onion, garlic, mustard, eggs, proteins, hair, wool, etc., contain sulphur compounds.

- 17. Sulphur exists in several allotropic forms. The most common form is the rhombic or octahedral or  $\alpha$ -form. It is pale yellow in colour. Its specific gravity is 2.06. It melts at 114.5°C. It is insoluble in water and readily soluble in CS2. It consists S8 structural units packed together into octahedral shape. This is the stable variety at ordinary temperature. All other forms such as monoclinic, plastic sulphur, etc., are unstable and convert themselves into rhombic form.
- 18. Hydrogen sulphide or sulphureted hydrogen (H<sub>2</sub>S) occurs in volcanic gases, sewage gases, coal gas and in several spring waters. It is found in small amounts in atmosphere. It is obtained in the laboratory by the action of dilute H<sub>2</sub>SO<sub>4</sub> on FeS in kipp's apparatus. Pure H<sub>2</sub>S can be prepared by the action of pure HCl on antimony sulphide (Sb<sub>2</sub>S<sub>3</sub>).

It cannot be dried by conc. H<sub>2</sub>SO<sub>4</sub> because it is oxidised to sulphur.

$$H_2S + H_2SO_4 \longrightarrow 2H_2O + S + SO_2$$

It is, therefore, dried by passing through  $CaCl_2$  or  $P_2O_5$ . It is a colourless gas with unpleasant odour. It is slightly heavier than air and slightly soluble in water. It is poisonous in nature. It burns with blue flame in oxygen or air forming  $SO_2$  and  $H_2O$ . It acts as a strong reducing agent. It reacts with metals and metal oxides to form corresponding sulphides.  $H_2S$  reacts with salts of various metals forming corresponding sulphides. The metal sulphides can be divided into three groups:

- (a) Sulphides precipitated in acidic medium—Examples : Sulphides of Hg, Bi, Pb, Cu, Ag, Cd, As, Sb and Sn.
- (b) Sulphides precipitated in alkaline medium—Examples : Sulphides of Zn, Ni, Co, Mn and Fe.
- (c) Sulphides which are precipitated neither in acidic nor in alkaline medium—Examples: Sulphides of Cr, Al, Mg, Ba, Sr, Ca, K and Na.

The shape of  $H_2S$  molecule is similar to that of water, *i.e.*, V-shaped. The bond length is 1.35Å and bond angle 92.5°.

19. Sulphur forms a number of oxides such as S<sub>2</sub>O, SO, S<sub>2</sub>O<sub>3</sub>, SO<sub>2</sub>, SO<sub>3</sub>, S<sub>2</sub>O<sub>7</sub> and SO<sub>4</sub>. Out of these SO<sub>2</sub> and SO<sub>3</sub> are important and common.

 $SO_2$  is a colourless gas with pungent and suffocating odour. It is heavier than air. It is soluble in water. It neither burns nor helps in burning. However, burning Mg or K continue to burn in its atmosphere.

$$3Mg + SO_2 \longrightarrow 2MgO + MgS;$$
  
 $4K + 3SO_2 \longrightarrow K_2SO_3 + K_2S_2O_3$ 

It is an acidic oxide. It dissolves in water forming sulphurous acid (H<sub>2</sub>SO<sub>3</sub>). It combines directly with chlorine to form sulphuryl chloride. It combines with oxygen in presence of a catalyst (platinised asbestos or V<sub>2</sub>O<sub>5</sub> or NO) when SO<sub>3</sub> is formed.

It acts as a reducing as well as an oxidising agent. In presence of moisture, it acts as a bleaching agent. The bleaching action is due to reduction. The bleaching is temporary.

20. A large number of oxyacids are known in the case of sulphur either in free state or in the form of salts or both. Oxyacids

with S—S links are called thioacids. Acids having sulphur in lower oxidation state belong to -ous series while those having sulphur in higher oxidation state belong to -ic series.

(a) Sulphurous acid (H<sub>2</sub>SO<sub>3</sub>): This acid is known only in solution. It is formed by passing SO<sub>2</sub> through water. It is a strong dibasic acid and forms two series of salts (i) bisulphites (e.g., NaHSO<sub>3</sub>) and (ii) sulphites (e.g., Na<sub>2</sub>SO<sub>3</sub>). The salts are fairly stable. The sulphurous acid, bisulphites and sulphites act as reducing agents. X-ray analysis of the crystal of Na<sub>2</sub>SO<sub>3</sub> has revealed that SO<sub>3</sub><sup>2-</sup> ion has a pyramidal structure. The S-atom is in sp<sup>3</sup> hybridized form, i.e., tetrahedral configuration in which

one position is occupied by a lone pair of electrons.

(b) Sulphuric acid (H<sub>2</sub>SO<sub>4</sub>): It is considered as king of chemicals. The prosperity of any country is measured by the amount of sulphuric acid it consumes. It was called in ancient days *oil of vitriol* as it was obtained by distilling ferrous sulphate (green vitriol). Native sulphur is the starting material for its preparation. It is burnt and is easily converted into SO<sub>2</sub>. The conversion of SO<sub>2</sub> into SO<sub>3</sub> is bit difficult. It requires a catalyst. The trioxide dissolves in water to form H<sub>2</sub>SO<sub>4</sub>.

$$S \longrightarrow SO_2 \longrightarrow SO_3 \longrightarrow H_2SO_4$$

Two processes are used for the manufacture of H<sub>2</sub>SO<sub>4</sub>.

- (i) Lead chamber process: In this process, the mixture containing SO<sub>2</sub>, air and NO when treated with steam, sulphuric acid is formed. NO is a catalyst. The acid obtained contains about 80% H<sub>2</sub>SO<sub>4</sub> and is known as brown oil of vitriol (B.O.V.) due to its colour. It can be further concentrated and the concentrated acid is called rectified oil of vitriol (R.O.V.). Usually chamber acid is not purified and used as such for most<sub>2</sub> of the purposes.
- (ii) Contact process: The process involves the conversion of SO<sub>2</sub> into SO<sub>3</sub> by air in presence of a catalyst (platinum or V<sub>2</sub>O<sub>5</sub>). Best results are obtained when SO<sub>2</sub> and O<sub>2</sub> are present in molecular proportion of 2:3. The optimum temperature is 450°C. The purification of gases is very necessary in this process. The SO<sub>3</sub> formed is absorbed in conc. H<sub>2</sub>SO<sub>4</sub> when oleum is formed. SO<sub>3</sub> cannot be absorbed in water because it produces a dense fog. The acid obtained is pure.

H<sub>2</sub>SO<sub>4</sub> is a colourless syrupy liquid. It contains 98.3% H<sub>2</sub>SO<sub>4</sub>. Its specific gravity is 1.84 at 15°C. It fumes strongly in moist air and highly corrosive in nature. It is highly soluble in water. Various hydrates such as H<sub>2</sub>SO<sub>4</sub>·H<sub>2</sub>O, H<sub>2</sub>SO<sub>4</sub>·2H<sub>2</sub>O, H<sub>2</sub>SO<sub>4</sub>·3H<sub>2</sub>O,

H<sub>2</sub>SO<sub>4</sub>·4H<sub>2</sub>O are known. Heat is evolved when dissolved in water. Water should not be added to conc. H<sub>2</sub>SO<sub>4</sub> for dilution but conc. H<sub>2</sub>SO<sub>4</sub> should be added slowly to cold water with constant stirring. Due to its great affinity for water, it is used as dehydrating agent. Its corrosive action on skin is due to dehydration. It boils at 338°C. It is a conductor of heat and electricity.

 $H_2SO_4$  is a strong dibasic acid. It forms two series of salts (i) bisulphates (e.g., NaHSO<sub>4</sub>) and (ii) sulphates (e.g., Na<sub>2</sub>SO<sub>4</sub>). It acts as a strong oxidising agent. The potential equation is:  $H_2SO_4 \longrightarrow H_2O + SO_2 + O$  or  $2H_2SO_4 + 2e \longrightarrow SO_4^{2-} + 2H_2O + SO_2$ . It has two OH groups which are directly attached to sulphur. The acid is a resonance hybrid of the following two structures.

 $SO_4^{2-}$  ion has tetrahedral structure, *i.e.*, S is in  $sp^3$  hybridization.

- (c) Thiosulphuric acid (H<sub>2</sub>S<sub>2</sub>O<sub>3</sub>): It is a dibasic acid. It does not exist in free state. Salts are quite stable. Thiosulphates are reducing agents.
- (d) Peroxymonosulphuric acid or Caro's acid (H<sub>2</sub>SO<sub>5</sub>): It is a dibasic stable and crystalline solid. It has a peroxolinkage OHOOH. It is a strong oxidising agent.
- (e) Peroxydisulphuric acid or Marshall's acid (H<sub>2</sub>S<sub>2</sub>O<sub>8</sub>): It is a dibasic acid. It has a peroxolinkage. It is a strong oxidising agent.

(f) Dilhionic acid (H<sub>2</sub>S<sub>2</sub>O<sub>6</sub>): It is a dibasic acid. It does not exist in free state but its salts are quite stable.

- 21. The IUPAC name of  $H_2S$  is sulphane.
- 22. (a) SF<sub>6</sub> is used in high voltage transformers because of its insulating property.
  - (b) Liquid oxygen mixed with finely divided carbon is used in place of dynamite in coal mining.
  - (c) A mixture of ozone and cyanogen is used as a rocket fuel.
  - (d) Gun powder is a mixture of sulphur, charcoal and KNO<sub>3</sub>.

- (e) S<sub>2</sub>Cl<sub>2</sub> is used in the vulcanisation of rubber.
- (f) Electrical conductivity of Se is negligible in dark but increases on exposure to light. Due to this property, Se is used in photo electric cells.
- 23. The chemical reactions of ozone with oxides of nitrogen and with chlorofluoro-alkanes are responsible for the depletion

of ozone shield of the atmosphere. This is called 'ozone hole'. It is feared that this will allow an excessive amount of UV light to reach the earth which will cause **melanoma** (skin cancer) in humans.

# -•••- PRACTICE PROBLEMS -•••-

### ■ Subjective Type Questions

- 1. Name the elements of group 16 which have:
  - (i) highest electronegativity
  - (ii) maximum ionisation enthalpy
  - (iii) highest catenation property
  - (iv) highest electropositive nature.
- 2. Among the hydrides of group 16 elements, which have :
  - (i) lowest boiling point
  - (ii) highest bond angle
  - (iii) maximum acidic nature
  - (iv) neutral in nature.
- 3. List the elements O, S, Se and Te in the order of decreasing: (i) boiling point (ii) electronegativity (iii) ionisation energy.
- 4. Sulphuric acid acts as an acid, an oxidising agent and as a dehydrating agent. In which way does it behave when it acts on:
  - (a) Glucose, (b) Sulphur, (c) Calcium carbonate, (d) Copper,
  - (e) Formic acid, (f) Hydrogen iodide, (g) Sodium hydroxide,
  - (h) Carbon.
- 5. What happens when?
  - Hydrogen sulphide is bubbled through an aqueous solution of sulphur dioxide.
  - (ii) Hydrogen sulphide is passed through acidified ferric chloride solution.
  - (iii) Sulphur is boiled with caustic soda solution.
  - (iv) Ozone reacts with potassium ferrocyanide solution.
  - (v) Ozone is treated with ethylene. [M.L.N.R. 1990]
  - (vi) Sulphur dioxide is bubbled through aqueous solution of copper sulphate in presence of potassium thiocyanate.
  - (vii) Sulphur dioxide gas, water vapour and air are passed over heated sodium chloride.
  - (viii) Sulphuric acid is treated with PCl<sub>5</sub>.
  - (ix) Ozone is passed through acidified stannous chloride solution.
  - (x) Potassium iodide is heated with conc. H<sub>2</sub>SO<sub>4</sub>.
- 6. Complete the following equations:
  - (i)  $(NH_4)_2S_2O_8 + H_2O + MnSO_4 \longrightarrow \dots + \dots + \dots$

[I.I.T. 1993]

(ii) 
$$S + H_2SO_4(conc.) \xrightarrow{Heat} \dots + H_2O$$

(iii) 
$$I_2 + SO_2 + H_2O \longrightarrow SO_4^{2-} + \dots + H^+$$

(iv) 
$$I_2 + O_3 + H_2O \longrightarrow HIO_3 + \dots$$

(v) 
$$Cr_2O_7^{2-} + H^+ + SO_2 \longrightarrow SO_4^{2-} + H_2O + \dots$$

- (vi)  $H_2S + HNO_3 \longrightarrow \dots + H_2O + S$  (Colloidal)
- (vii)  $Fe^{2+} + SO_3^{2-} + H^+ \longrightarrow Fe^{3+} + H_2O + S$
- (viii)  $Mn^{2+} + S_2O_8^{2-} + H_2O \longrightarrow MnO_4^- + H^+ + SO_4^{2-}$
- (ix)  $MnO_4^- + H_2S \longrightarrow S + Mn^{2+} + H_2O$  (Acidic medium)
- 7. From the reactions given below, identify (A), (B), (C) and (D) and their formulae.
  - (A) + dil.  $H_2SO_4$  +  $K_2Cr_2O_7$   $\longrightarrow$  (B) Green coloured

$$(A) + \text{dil. } H_2SO_4 + (C) \longrightarrow MnSO_4$$

$$(A) + O_2 \xrightarrow{H_2O} (D)$$
  
 $(D) + BaCl_2 \longrightarrow White ppt.$ 

- 8. Arrange the following:
  - (a) H<sub>2</sub>S, H<sub>2</sub>O, H<sub>2</sub>Se, H<sub>2</sub>Te in order of increasing acidity.
  - (b) H<sub>2</sub>O, H<sub>2</sub>S, H<sub>2</sub>Se, H<sub>2</sub>Te in order of increasing stability.
  - (c) H<sub>2</sub>O, CO<sub>2</sub>, SO<sub>3</sub>, N<sub>2</sub>O<sub>5</sub>, SiO<sub>2</sub> in order of decreasing acidity.
  - (d) Po, Se, Te, S, O in order of increasing metallic properties.
  - (e) Po, Se, Te, S, O in order of decreasing ionisation potential.
- 9. Give at least one example to explain the following properties:
  - (i) Sulphuric acid is a dibasic acid.
  - (ii) Sulphuric acid is a dehydrating agent.
  - (iii) Conc. H<sub>2</sub>SO<sub>4</sub> acts as an oxidising agent.
  - (iv) H<sub>2</sub>S acts as a reducing agent.
  - (v) SO<sub>2</sub> acts as a reducing agent.
  - (vi) SO<sub>3</sub> is an acid anhydride of H<sub>2</sub>SO<sub>4</sub>.
- 10. A mixture of three gases A, B and C is passed first through acidified  $K_2Cr_2O_7$  solution when A is absorbed turning  $K_2Cr_2O_7$  solution green. Remainder is passed through excess of lime water which turns milky resulting in absorption of B. The residual gas C is absorbed in alkaline pyrogallol solution. The mixture of A; B and C does not turn lead acetate paper black. Identify A, B and C.
- 11. Answer the following:
  - (i) Write the general electronic configuration of VIA or 16th group.
  - (ii) Name two chalcogens.
  - (iii) Which element of VIA group has maximum catenation property?
  - (iv) Name the hydride of VIA group elements which is liquid at room temperature.
  - (v) Which allotropic form of sulphur is more stable at room temperature?

- (vi) Which gas is formed in the upper layers of atmosphere by action of UV radiations?
- (vii) The common oxidation states of VIA group elements are . . . . . .
- (viii) What is the other name of peroxy disulphuric acid?
- (ix) Name the acid used in storage batteries.
- (x) What is the reason for the syrupy nature of conc. H<sub>2</sub>SO<sub>4</sub>?
- (xi) Among the hydrides, H<sub>2</sub>O, H<sub>2</sub>S, H<sub>2</sub>Se, which has the highest bond angle?
- (xii) Write the formula of oleum.
- (xiii) Which catalyst is used in the manufacture of H<sub>2</sub>SO<sub>4</sub> by contact process? [M.L.N.R. 1997]
- (xiv) What are the most favourable conditions of temperature and pressure for the conversion of  $SO_2$  into  $SO_3$ ?
- (xv) The other name of sulphuric acid is . . . . . .
- 12. Write the hybridization state of the central atom, shape and electronic structure of the following molecules or ions.
  - (i) Sulphur trioxide,
- (iv) Sulphate ion
- (ii) Sulphuric acid,
- (v) Ozone
- (iii) Sulphur dioxide,
- (vi) Hydrogen sulphide
- 13. Explain the following:
  - (i) Oxygen is a gas while sulphur is a solid.

[Ans. The oxygen molecule is diatomic involving a double bond. Its small size produces weak intermolecular forces amongst its molecules and is, thus, a gas at room temperature. Sulphur is incapable of forming  $\pi$ -bonds. Its molecule has a puckered ring structure of eight sulphur atoms joined by single covalent bonds. The intermolecular forces acting between  $S_8$  molecules are stronger and hence, sulphur is a solid.]

(ii) Water is liquid while H<sub>2</sub>S is a gas.

to form a cluster.

[Ans. Oxygen is more electronegative than sulphur. Thus, oxygen can form hydrogen bonds. Water is an associated liquid due to hydrogen bonding. The hydrogen bonding is absent in H<sub>2</sub>S, hence the molecules are unassociated. It, therefore, exists in gaseous state.]

(iii) Sulphuric acid has high boiling point and viscosity.
 [Ans. The high boiling point and viscous nature of conc.
 H<sub>2</sub>SO<sub>4</sub> is due to hydrogen bonding due to which a number of sulphuric acid molecules are associated

(iv) Oxygen almost invariably exhibits an oxidation state of -2 but the other members of the family exhibit negative as well as positive oxidation states of +2, +4 and +6.

[Ans. All the elements of oxygen family have a configuration of  $ns^2$   $np^4$  of the outermost orbit. They all tend to attain 8 electrons by accepting two more electrons, *i.e.*, all show -2 oxidation state. Oxygen has no d-orbitals while, others have d-orbitals in their valency shells. Thus, the paired

orbitals can be unpaired by shifting electrons to d-orbitals.

+4	ns	np	nd	
Ground state	$\uparrow\downarrow$	$\uparrow\downarrow\uparrow\uparrow$		+2 oxidation state
1st excited state	$\uparrow$	$\boxed{\uparrow   \uparrow   \uparrow}$	$\uparrow$	+4 oxidation state
2nd excited state	$\uparrow$	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	$\uparrow \uparrow \uparrow$	+6 oxidation state

The elements of oxygen family except oxygen, therefore, show +2, +4 and +6 oxidation states besides -2.]

(v) The tendency to show -2 oxidation state diminishes from sulphur to polonium.

[Ans. On moving down the group, the size of the atom increases and the electronegativity decreases. Thus, the tendency to accept two more electrons as to attain octet in outermost shell decreases, i.e., the tendency to show -2 oxidation state decreases.]

(vi) Sulphur dioxide is more powerful reducing agent in an alkaline medium than in acidic medium. [I.I.T. 1992]

[Ans. The reducing property is represented as,

$$SO_2 + 2OH^- \longrightarrow SO_4^{2-} + 2H^+ + 2e^-$$

Addition of acid favours reverse reaction whereas presence of OH<sup>-</sup> favours the forward reaction.]

(vii) Dry SO<sub>2</sub> does not bleach dry flowers.

[Ans. Only in presence of moisture, the nascent hydrogen responsible for bleaching (reduction) is produced.

$$SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2H$$
  
Coloured flower + H  $\longrightarrow$  Colourless flower ]

(viii) H<sub>2</sub>S is stronger acid than H<sub>2</sub>O.

[Ans. The H—S bond is weaker than H—O bond and the proton is more easily released when H<sub>2</sub>S reacts with water.]

(ix) Hydrogen sulphide cannot be dried by passing through conc. H<sub>2</sub>SO<sub>4</sub>.

[Ans. Conc. H<sub>2</sub>SO<sub>4</sub> is an oxidising agent while H<sub>2</sub>S is a reducing agent. Both react to form free sulphur.]

(x) Nitric acid cannot be used to prepare  $H_2S$ . [Ans. Nitric acid is an oxidising agent. It will oxidise  $H_2S$ .  $3H_2S + 2HNO_3 \longrightarrow 2NO + 3S + 4H_2O$ 

(xi) In the manufacture of sulphuric acid by the contact process, sulphur trioxide is not directly dissolved in water.

[Ans.  $SO_3$  reacts with water to form  $H_2SO_4$  which is not easily condensed and escapes in the atmosphere. It is, therefore, absorbed in conc.  $H_2SO_4$  to form oleum which may be diluted to form  $H_2SO_4$ .

$$H_2SO_4 + SO_3 \longrightarrow H_2S_2O_7$$
  
 $H_2S_2O_7 + H_2O \longrightarrow 2H_2SO_4$ 

(xii) For the dilution of H<sub>2</sub>SO<sub>4</sub>, water should not be added to conc. H<sub>2</sub>SO<sub>4</sub>.

[Ans. Conc. H<sub>2</sub>SO<sub>4</sub> has great affinity for water molecules.

During addition of water, large amount of heat energy is released. The temperature rises suddenly and bumping takes place. To avoid any accident, acid

should be added to water with constant stirring rather than water to acid.]

(xiii) Conc. H<sub>2</sub>SO<sub>4</sub> cannot be used for drying H<sub>2</sub>. [Ans. Hydrogen, sometimes, ignites with the large amount of heat released when water is absorbed by acid.]

(xiv) The bond angle in  $H_2S$  is lower than in  $H_2O$ .

[Ans. S is less electronegative than oxygen. The bonded electrons in H<sub>2</sub>S move further away from S-atom than O-atom in H2O. This decreases repulsion between bonded electrons and thus, there is contraction in bond angle.]

(xv) KMnO<sub>4</sub> should not be dissolved in conc. H<sub>2</sub>SO<sub>4</sub>. [Ans. Mn<sub>2</sub>O<sub>7</sub> is formed which is unstable and explosive in nature.

$$2KMnO_4 + 2H_2SO_4 \longrightarrow K_2SO_4 + (MnO_3)_2SO_4 + 2H_2O$$
  
 $(MnO_3)_2SO_4 + H_2O \longrightarrow Mn_2O_7 + H_2SO_4$ 

(xvi) Ozone layer in the upper regions of atmosphere protects earth from the harmful radiations of sun.

> [Ans. Harmful UV radiations are emitted by sun. The ozone layer is capable of absorbing these radiations and thus protects the earth from these radiations.]

- 14. An aqueous solution of a gas (X) gives the following reactions:
  - (i) It decolourizes an acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution.
  - On boiling with H<sub>2</sub>O<sub>2</sub>, cooling it and then adding an aqueous solution of BaCl<sub>2</sub>, a precipitate insoluble in dil. HCl is obtained.
  - (iii) On passing H<sub>2</sub>S in the solution, white turbidity is obtained. Identify (X) and give equations for steps (i), (ii) and (iii). [Roorkee 1993]

[Hint: Step (iii) suggests that 
$$(X)$$
 is  $SO_2$ .

$$SO_2 + 2H_2S \longrightarrow 3S + 2H_2O$$
Turbidity

(i) 
$$K_2Cr_2O_7 + H_2SO_4 + 3SO_2 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O$$
  
Colourless solution

(ii) 
$$\begin{array}{ccc} H_2O_2 + SO_2 & \longrightarrow & H_2SO_4 \\ H_2SO_4 + BaCl_2 & \longrightarrow & BaSO_4 + 2HCl \ ] \\ & & & White ppt. \end{array}$$

15. A pale yellow substance (A) when heated with conc. HNO<sub>3</sub> evolves a brown coloured gas (B). The substance (A) also dissolves in sodium sulphite solution on heating. A clear solution (C) is formed which on acidification gives a turbid solution and a pungent smelled gas (D) which is formed by the substance (A) in air. The solution (C) decolourises iodide solution. Identify (A) to (D).

[Hint: Substance (A) is sulphur.

$$\begin{array}{c} S + 6HNO_3 \longrightarrow H_2SO_4 + 2H_2O + 6NO_2 \\ (A) & (B) \\ S + Na_2SO_3 \longrightarrow Na_2S_2O_3 \\ (A) & (C) \\ Na_2S_2O_3 + H_2SO_4 \longrightarrow Na_2SO_4 + SO_2 + S + H_2O \\ (C) & (D) \text{ Turbidity} \\ 2Na_2S_2O_3 + I_2 \longrightarrow Na_2S_4O_6 + 2NaI ] \\ (C) & \text{Colourless solution} \end{array}$$

16. An inorganic halide (A) reacts with water to form two acids (B) and (C). (A) also reacts with NaOH to form two salts (D) and (E) which remain in solution. The solution gives white precipitates with both AgNO3 and BaCl2 solutions respectively. (A) is a useful organic reagent. [Hint:  $A = SO_2Cl_2$ 

$$SO_2Cl_2 + 2H_2O \longrightarrow H_2SO_4 + 2HCl$$

$$(A) \qquad (B) \qquad (C)$$

$$SO_2Cl_2 + 4KOH \longrightarrow K_2SO_4 + 2KCl + 2H_2O$$

$$(A) \qquad (D) \qquad (E)$$

$$BaCl_2 \qquad AgNO_3$$

$$BaSO_4 \qquad AgCl \qquad ]$$
Whiteppt. Whiteppt.

17. In the contact process for industrial manufacture of sulphuric acid some amount of sulphuric acid is used as a starting material. Explain briefly. What is the catalyst used in the [LLT. 1999] oxidation of SO<sub>2</sub>?

### Matching Type Questions

### Match the following:

[A] (a) Oleum

(i) NO·HSO<sub>4</sub>

(b) Peroxy disulphuric acid

(ii) H<sub>2</sub>SO<sub>5</sub>

(c) Peroxy monosulphuric acid

(iii) H<sub>2</sub>SO<sub>3</sub>

Chamber crystals

(iv)  $H_2S_2O_7$ 

Sulphurous acid

(v)  $H_2S_2O_8$ 

[B] (i) Sulphur dioxide

(a) Laboratory reagent for mixture analysis

(ii) Oxygen

(b) Oleum

(iii) Ozone

(c) Vulcanizing rubber

(iv) Hydrogen sulphide

(d) Petroleum refining

(v) Sulphur

(vi) Sulphuric acid

(e) Paramagnetic

Marshall's acid

(vii) Fuming sulphuric acid

(g) Antichlor

(viii) Peroxy disulphuric acid (h) Detection of double

bond in organic compounds.

## Answers

### **Answers**: Subjective Type Questions

- 1. (i) oxygen (ii) oxygen (iii) sulphur (iv) polonium or ununhexium
- 2. (i)  $H_2S$  (ii)  $H_2O$  (iii)  $H_2Te$  or  $H_2Po$  (iv)  $H_2O$
- 3. (i) Te > Se > S > O
  - (ii) O > S > Se > Te
  - (iii) O > S > Se > Te
- 4. (a) dehydrating agent, (b) oxidising agent, (c) an acid, (d) oxidising agent, (e) dehydrating agent, (f) oxidising agent, (g) an acid, (h) oxidising agent.
- 5. (i) (Moist)  $SO_2 + 2H_2S \longrightarrow 3S + 2H_2O$ 
  - (ii)  $2\text{FeCl}_3 + \text{H}_2\text{S} \longrightarrow 2\text{FeCl}_2 + 2\text{HCl} + \text{S}$
  - (iii)  $4S + 6NaOH \longrightarrow Na_2S_2O_3 + 2Na_2S + 3H_2O$

Excess sulphur Na<sub>2</sub>S<sub>5</sub>

(iv)  $2K_4Fe(CN)_6 + O_3 + H_2O \longrightarrow 2K_3Fe(CN)_6 + 2KOH + O_2$ 

$$(v) \qquad CH_2 = CH_2 + O_3 \longrightarrow CH_2 \qquad CH_2$$

$$O \longrightarrow O$$

(vi)  $2CuSO_4 + SO_2 + 2KCNS + 2H_2O \longrightarrow$ 

 $2CuCNS + K_2SO_4 + 2H_2SO_4$ 

(vii)  $2SO_2 + O_2 + 2H_2O \longrightarrow 2H_2SO_4$  $2NaCl + H_2SO_4 \longrightarrow Na_2SO_4 + 2HCl$ 

(viii)  $H_2SO_4 + 2PCl_5 \longrightarrow SO_2Cl_2 + 2POCl_3 + 2HCl$ 

- (ix)  $3\operatorname{SnCl}_2 + 6\operatorname{HCl} + \operatorname{O}_3 \longrightarrow 3\operatorname{SnCl}_4 + 3\operatorname{H}_2\operatorname{O}$
- (x)  $2KI + H_2SO_4 \longrightarrow K_2SO_4 + 2HI$

 $2HI + H_2SO_4 \longrightarrow I_2 + SO_2 + 2H_2O$ 

6. (i)  $(NH_4)_2S_2O_8 + H_2O \longrightarrow (NH_4)_2SO_4 + H_2SO_4 + O$  $MnSO_4 + H_2O + O \longrightarrow MnO_2 + H_2SO_4$ 

### $(NH_4)_2S_2O_8 + MnSO_4 + 2H_2O \longrightarrow (NH_4)_2SO_4 + MnO_2 + 2H_2SO_4$

- (ii)  $S + 2H_2SO_4 \longrightarrow 3SO_2 + 2H_2O$
- (iii)  $I_2 + SO_2 + 2H_2O \longrightarrow SO_4^{2+} + 2I^- + 4H^+$
- (iv)  $I_2 + 5O_3 + H_2O \longrightarrow 2HIO_3 + 5O_2$
- (v)  $Cr_2O_7^{2-} + 2H^+ + 3SO_2 \longrightarrow 3SO_4^{2-} + H_2O + 2Cr^{3+}$
- (vi)  $H_2S + 2HNO_3 \longrightarrow 2NO_2 + 2H_2O + S$  (colloidal)
- (vii)  $4Fe^{2+} + SO_3^{2-} + 6H^+ \longrightarrow 4Fe^{3+} + S + 3H_2O$
- (viii)  $2Mn^{2+} + 5S_2O_8^{2-} + 8H_2O \longrightarrow 2MnO_4^{-} + 16H^{+} + 10SO_4^{2-}$
- $(ix) \quad 2MnO_4^- + 6H^+ + 6H_2S \longrightarrow 2Mn^{2+} + 5S + 8H_2O$
- 7.  $(A) = \text{Na}_2\text{SO}_3$ ;  $(B) = \text{Cr}_2(\text{SO}_4)_3$ ;  $(C) = \text{KMnO}_4$ ;  $(D) = \text{Na}_2\text{SO}_4$
- 8. (a)  $H_2O < H_2S < H_2Se < H_2Te$ 
  - (b)  $H_2Te < H_2Se < H_2S < H_2O$
  - (c)  $SO_3 > N_2O_5 > CO_2 > SiO_2 > H_2O$
  - (d) O < S < Se < Te < Po
  - (e) O > S > Se > Te > Po
- (i) One molecule of H<sub>2</sub>SO<sub>4</sub> consists two replaceable hydrogen atoms and forms two series of salts.

NaOH + H<sub>2</sub>SO<sub>4</sub> 
$$\longrightarrow$$
 NaHSO<sub>4</sub> + H<sub>2</sub>O

Sodium hydrogen
sulphate (acidic salt)

$$\begin{array}{ccc} 2NaOH + H_2SO_4 & \longrightarrow & Na_2SO_4 & + \ 2H_2O \\ & & \text{Sodium sulphate} \\ & & \text{(normal salt)} \end{array}$$

(ii) H<sub>2</sub>SO<sub>4</sub> has great affinity for water molecules, and hence it acts as a dehydrating agent.

$$C_{12}H_{22}O_{11} \xrightarrow{H_2SO_4} 12C + 11H_2O$$
Sugar
$$C_{arbon} + 11H_2O$$

$$C_{arbon} + 11H_2O$$

$$C_{arbon} + 11H_2O$$

(iii) H<sub>2</sub>SO<sub>4</sub> oxidises metals, non-metals and other compounds. Sulphur in H<sub>2</sub>SO<sub>4</sub> is in +6 oxidation state, thus it can change into-lower-oxidation-states, *i.e.*, +4, -2, etc.

Cu + 
$$2H_2SO_4$$
 (conc.)  $\longrightarrow$  CuSO<sub>4</sub> + SO<sub>2</sub> +  $2H_2O$   
 $2P + 5H_2SO_4 \longrightarrow 2H_3PO_4 + 2H_2O + 5SO_2$   
 $2HBr + H_2SO_4 \longrightarrow SO_2 + Br_2 + 2H_2O$ 

(iv) Sulphur in  $H_2S$  is in -2 oxidation state, thus it can increase the oxidation state only and hence it acts as a reducing agent.

$$H_2S + Cl_2 \longrightarrow 2HCl + S$$
  
 $H_2S + 2HNO_3 \longrightarrow 2NO_2 + 2H_2O + S$ 

(v) As it can be oxidised to sulphuric acid, it acts as a reducing agent.

$$SO_2 \longrightarrow H_2SO_4$$

$$O.N. +4 +6$$

$$Cl_2 + 2H_2O + SO_2 \longrightarrow H_2SO_4 + 2HCl$$

$$2FeCl_3 + 2H_2O + SO_2 \longrightarrow H_2SO_4 + 2FeCl_2 + H_2SO_4$$

(vi) SO<sub>3</sub> combines with water to form H<sub>2</sub>SO<sub>4</sub>, hence it is an acid anhydride of H<sub>2</sub>SO<sub>4</sub>.

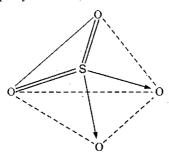

$$SO_3 + H_2O \longrightarrow H_2SO_4$$

- **10.** A is SO<sub>2</sub> as it turns acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution green. (It is not H<sub>2</sub>S as it does not turn lead acetate paper black.) B is CO<sub>2</sub> as it turns lime water milky and C is oxygen which is absorbed in alkaline pyrogallol.
- 11. (i)  $ns^2 np^4$ , (ii) Oxygen and sulphur, (iii) Sulphur, (iv) Water, H<sub>2</sub>O, (v) Rhombic, (vi) Ozone, (vii) -2, +2, +4, +6, (viii) Marshall acid, (ix) H<sub>2</sub>SO<sub>4</sub>, (x) Intermolecular hydrogen bonding, (xi) H<sub>2</sub>O,
  - (xii) H<sub>2</sub>S<sub>2</sub>O<sub>7</sub>, (xiii) Platinised asbestos or vanadium pentoxide, (xiv) Low temperature (optimum temperature 450°C) and high pressure (optimum pressure 2 to 3 atmospheres), (xv) Oil of vitriol.
- 12. (i)  $SO_3$ ,  $sp^2$  hybridization, planar triangular

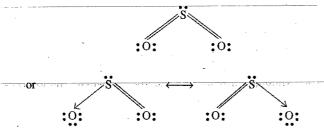

The equivalence of all S—O bonds suggest that  $SO_3$  is a resonance hybrid of the following structures :

(ii) H<sub>2</sub>SO<sub>4</sub>, sp<sup>3</sup> hybridization, tetrahedral

(iii) SO<sub>2</sub>, sp<sup>2</sup> hybridization, V-shaped

(iv) O<sub>3</sub>, sp<sup>2</sup> hybridization, angular (V-shaped)

(v) H<sub>2</sub>S, sp<sup>3</sup> hybridization, V-shaped

## ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. Concentrated H<sub>2</sub>SO<sub>4</sub> can be used to dry the gas:
  - (a) H<sub>2</sub>S

(b) CO<sub>2</sub>

(c) NH<sub>3</sub>

(d) all

Ans. (b)

[Hint: H<sub>2</sub>S and NH<sub>3</sub> react with H<sub>2</sub>SO<sub>4</sub> while CO<sub>2</sub> is not affected.

- 2. Sulphur on reaction with concentrated HNO<sub>3</sub> gives (A) which reacts with NaOH gives (B). (A) and (B) are:
  - (a) H<sub>2</sub>SO<sub>3</sub>, Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>
- (b) NO2, Na2S
- (c) H<sub>2</sub>SO<sub>4</sub>, Na<sub>2</sub>SO<sub>4</sub>
- (d)  $H_2S_2O_3$ ,  $Na_2S_2O_3$

Ans. (c)

Hint:

$$6 \text{HNO}_3 + \text{S} \longrightarrow \text{H}_2 \text{SO}_4 + 6 \text{NO}_2 + 2 \text{H}_2 \text{O} \; ;$$
 
$$(A) \\ \text{H}_2 \text{SO}_4 + 2 \text{NaOH} \longrightarrow \text{Na}_2 \text{SO}_4 + 2 \text{H}_2 \text{O} \; ]$$
 
$$(B)$$

$$H_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2H_2O$$
(B)

- 3. The structures of  $O_3$  and  $N_3^-$  are:
  - (a) linear and bent respectively
  - (b) both linear
  - (c) both bent
  - (d) bent and linear respectively

Ans. (d)

- 4. When an inorganic compound reacts with SO<sub>2</sub> in aqueous medium produces (A). (A) on reaction with Na<sub>2</sub>CO<sub>3</sub> gives the compound (B) which with sulphur gives a substance (C) used in photography. The compound (C) is:
  - Ans. (a)
  - (a)  $Na_2S_2O_3$  (b)  $Na_2SO_4$  (c)  $Na_2S$

[Hint:  $Na_2CO_3 + 2SO_2 + H_2O \longrightarrow 2NaHSO_3 + CO_2$ 

(d) Na<sub>2</sub>S<sub>2</sub>O<sub>7</sub>

$$2NaHSO_3 + Na_2CO_3 \longrightarrow 2Na_2SO_3 + H_2O + CO_2$$

$$(B)$$

$$Na_2SO_3 + S \longrightarrow Na_2S_2O_3$$

$$(C)$$

- 5. Acidified KMnO<sub>4</sub> is dropped over sodium peroxide taken in a flask at room temperature, vigorous reaction takes place to produce:
  - (a) hydrogen peroxide
  - (b) a mixture of hydrogen and oxygen
  - (c) a colourless gas hydrogen
  - (d) a colourless gas dioxygen

Ans. (d)

[Hint: 
$$[Na_2O_2 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O_2] \times 5$$
  
 $2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5O$   
 $[H_2O_2 + O \longrightarrow H_2O + O_2] \times 5$ 

$$2KMnO_4 + 8H_2SO_4 + 5Na_2O_2 \longrightarrow 5Na_2SO_4 + K_2SO_4 + 2MnSO_4 \\ + 8H_2O + 5O_2]$$

Among the oxides given below which are acidic?

CrO<sub>3</sub>, Mn<sub>2</sub>O<sub>7</sub>, CuO, CO, SO<sub>2</sub>

- (a) Only SO<sub>2</sub>
- (b) CrO<sub>3</sub>, Mn<sub>2</sub>O<sub>7</sub> and SO<sub>2</sub>
- (c) Mn<sub>2</sub>O<sub>7</sub> and SO<sub>2</sub>
- (d) CO and SO<sub>2</sub>

Ans. (b)

[Hint: 
$$CrO_3 + H_2O \longrightarrow H_2CrO_4$$
;  
 $Mn_2O_7 + H_2O \longrightarrow 2HMnO_4$ ;  
 $SO_2 + H_2O \longrightarrow H_2SO_3$ 

CuO is a basic oxide while CO is a neutral oxide.]

- 7. In which of the following reactions  $O_2$  is not formed as one of the product?
  - (a) KClO<sub>3</sub> MnO<sub>2</sub> Heat

- (b)  $SnCl_2 + HCl + O_3 \longrightarrow$
- (c)  $FeSO_4 + H_2SO_4 + O_3 \longrightarrow$
- (d) PbS +  $O_3 \longrightarrow$

Ans. (b)

[Hint:  $3SnCl_2 + 6HCl + O_3 \longrightarrow 3SnCl_4 + 3H_2O$ ]

- **8.** The formation of which of the substance is known as tailing of mercury?
  - (a) Hg<sub>2</sub>O
- (b) HgO
- (c)  $Hg(NO_3)_2$
- (d) HgS

- Ans. (a)
- 9. Which of the following elements forms  $p\pi$ - $d\pi$  bonding in its oxide?
  - (a) Lithium
- (b) Boron
- (c) Sulphur
- (d) Nitrogen

Ans. (c)

[Hint: Among the given elements, sulphur forms  $d\pi$ - $p\pi$  bonding in its oxides such as SO<sub>2</sub> and SO<sub>3</sub>.]

10. In which of the following species, S-atom assumes sp<sup>3</sup> hybrid state?

 $I(SO_3); II(SO_2); III(H_2S); IV(S_8)$ 

(a) I, II

- (b) II, III
- (c) II, IV

(d) III, IV

Ans: (d)

- 11. Which of the following chemical reactions depicts the oxidising behaviour of H<sub>2</sub>SO<sub>4</sub>? [A.I.E.E.E. 2006]
  - (a)  $2HI + H_2SO_4 \longrightarrow I_2 + SO_2 + 2H_2O$
  - (b)  $Ca(OH)_2 + H_2SO_4 \longrightarrow CaSO_4 + 2H_2O$
  - (c)  $NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl$
  - (d)  $2PCl_5 + H_2SO_4 \longrightarrow 2POCl_3 + 2HCl + SO_2Cl_2$

Ans. (a)

[Hint: In reaction (a), the O.N. of S reduces from +6 to +4.]

- **12.** The number of unpaired electrons in a paramagnetic diatomic molecule of an element with atomic number 16 is:
  - (a) 4

(b) 1

(c) 2

(d) 3

Ans. (c)

[Hint: S<sub>2</sub> molecule is paramagnetic like O<sub>2</sub> having 2 unpaired electrons.]

13. The molecular formula of dithionic acid is:

[C.E.T. (J&K) 2006]

- (a)  $H_2S_2O_4$
- (b)  $H_2S_2O_6$
- (c)  $H_2S_2O_5$
- (d)  $H_2S_2O_8$

Ans. (b)

14. Which among the following statements are correct?

### [P.E.T. (Kerala) 2007]

- (i) Carbon monoxide is neutral whereas SO3 is acidic
- (ii) Potassium oxide is basic whereas nitrous oxide is acidic
- (iii) Aluminium and zinc oxides are amphoteric
- (iv) Sulphur trioxide is acidic whereas phosphorus pentoxide is basic
- (v) Carbon dioxide is neutral whereas sulphur dioxide is amphoteric
- (a) (ii) and (iii)
- (b) (i) and (iv)
- (c) (i) and (iii)
- (d) (ii) and (iv)
- (e) (iii) and (v)
- Ans. (c)
- 15. Ozone is used for purifying water because: [C.P.M.T. 2007]
  - (a) it dissociates and release oxygen
  - (b) it does not leave any foul smell like chlorine
  - (c) it kills bacteria, cyst, fungi and acts as a biocide
  - (d) all of the above

Ans. (d)

## **OBJECTIVE QUESTIONS**

			- 11 V II.		<u>. The control of the second s</u>			
Set	I: This set contains que	estions with one correct a	nswe	er.	•			
1.	The formula of sulphur mo	lecule is:		14.	The number of unpaired	elect	rons in the $p$ -subshell of $\nabla$	VΙΑ
	(a) $S_2$	☐ (b) S <sub>4</sub>			or 16th group of the period	odic	table is:	
	(c) $S_6$	$\square$ (d) $S_8$			(a) 1		(b) 2	
2.	The most stable allotropic	form of sulphur is:			(c) 3		(d) 4	
	(a) rhombic	(b) monoclinic		15.	Which shows maximum of	cater	nation property?	
	(c) plastic	☐ (d) milk of sulphur			(a) Te		(b) Se	
3.	Ozone is:	_			(c) S		(d) O	
	(a) compound of oxygen			16.	Ozone readily dissolves i	n:		
	(b) allotrope of oxygen				(a) H <sub>2</sub> O		(b) CS <sub>2</sub>	
	(c) isotope of oxygen	-			(c) turpentine oil		(d) ammonia	
	(d) mixture of atomic and r	nolecular oxygen		17.	The maximum bond angle	is i	and the second s

## Objective Questions for IIT ASPIRANTS

- 1. When sulphur is boiled with Na<sub>2</sub>SO<sub>3</sub>, a compound (A) is produced. (A) with excess of AgNO3 solution gives a compound (B) which is water soluble and produces a black coloured sulphide (C). Compounds (A), (B) and (C) will be respectively:
  - (a) Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, Ag<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, Ag<sub>2</sub>S
  - (b) Na<sub>2</sub>SO<sub>4</sub>, Ag<sub>2</sub>SO<sub>4</sub>, Ag<sub>2</sub>S
  - (c) Na<sub>2</sub>S<sub>2</sub>O<sub>7</sub>, Ag<sub>2</sub>SO<sub>4</sub>, Ag<sub>2</sub>S
  - (d) Na<sub>2</sub>SO<sub>5</sub>, Ag<sub>2</sub>SO<sub>5</sub>, Ag<sub>2</sub>SO<sub>4</sub>

[Hint: 
$$Na_2SO_3 + S \longrightarrow Na_2S_2O_3$$
;  
 $Na_2S_2O_3 + 2AgNO_3 \longrightarrow 2NaNO_3 + Ag_2S_2O_3$ ;  
 $Ag_2S_2O_3 + H_2O \longrightarrow Ag_2S + H_2SO_4$ ]

- 2. An organic acid (A) reacts with concentrated H<sub>2</sub>SO<sub>4</sub> to give a neutral oxide (B), acidic oxide (C) and a diatomic oxide (D). When (D) reacts with chlorine gas, a poisonous gas (E) is evolved. This gas with ammonia gives an organic compound (F). The compounds (A) and (F) are:
  - (a)  $(A) = H_2C_2O_4$  and  $(F) = NH_2CONH_2$
  - (b)  $(A) = CH_3COOH$  and  $(F) = NH_2CONH_2$
  - (c)  $(A) = CHCl_3$  and  $(F) = H_2C_2O_4$
  - (d)  $(A) = CCl_4$  and  $(F) = CH_3CHO$

$$[ \text{Hint} : (COOH)_2 \xrightarrow{Conc. H_2SO_4} H_2O + CO_2 + CO \\ (A) & (B) & (C) & (D) \\ Neutral & Acidic & Diatomic oxide \\ CO + Cl_2 \longrightarrow COCl_2 \xrightarrow{NH_3} NH_2CONH_2 ] \\ (E) & (F) \\ Poisonous$$

- 3. Compounds A and B are treated with dilute HCl separately. The gases liberated are Y and Z respectively. Y turns acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> paper green while Z turns lead acetate paper black. The compounds A and B are respectively:
  - (a) Na<sub>2</sub>S and Na<sub>2</sub>SO<sub>3</sub>
- (b) Na<sub>2</sub>SO<sub>3</sub> and Na<sub>2</sub>S
- (c) NaCl and Na<sub>2</sub>CO<sub>3</sub>
- (d) Na<sub>2</sub>SO<sub>3</sub> and Na<sub>2</sub>SO<sub>4</sub>

[Hint: SO<sub>2</sub> turns acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> paper green.

$$Na_2SO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + SO_2 + H_2O_4$$

 $K_2 Cr_2 O_7 + H_2 SO_4 + 3SO_2 \longrightarrow Cr_2 (SO_4)_3 + K_2 SO_4 + H_2 O$ 

 $H_2S$  turns lead acetate paper black.

$$Na_2S + H_2SO_4 \longrightarrow Na_2SO_4 + H_2S$$

$$H_2S + Pb(CH_3COO)_2 \longrightarrow PbS + 2CH_3COOH_3$$

- 4. A yellow coloured crystalline substance gave a colourless gas X on reaction with fluorine, which is thermally stable and has octahedral geometry. X can be:
  - (a)  $SF_4$

(c)  $SF_6$ 

- (d)  $S_2F_6$
- The number of lone pairs and the number of S—S bonds in S<sub>8</sub> molecules are respectively:

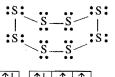

(a) 8,8

(b) 16,8

(c) 8, 16

(d) 8, 4

[Hint:  $S_8$  molecule is shown here. Every sulphur atom is in  $sp^3$ hybridized state.

 $\uparrow\downarrow$   $\uparrow\downarrow$   $\uparrow$   $\uparrow$ 

Thus, there are 8 S-S bonds and 16 lone pairs.]

- 6. Tailing of mercury test can be used for which of the following gas?
  - (a) Dioxygen
- (b) Dihydrogen
- (c) Dinitrogen
- (d) Ozone
- Which of the following solutions does not change its colour on passing ozone through it?
  - (a) Starch iodide solution
  - (b) Alcoholic solution of benzidine
  - (c) Acidic solution of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>
  - (d) Acidified solution of FeSO<sub>4</sub>

[Hint: Ozone does not react with acidified solution of  $K_2Cr_2O_7$ .]

- 8. A green coloured solution of a salt changes its colour to light pink on passing ozone through it. Which of the following species represent pink and green colour respectively?
  - (a) Mn<sup>2+</sup> and MnO<sub>2</sub> (c) Co<sup>2+</sup> and Co<sup>3+</sup>
    - (b)  $MnO_4^-$  and  $MnO_4^{2-}$ (d)  $MnO_4^{2-}$  and  $MnO_4^{-}$

[Hint: MnO<sub>4</sub><sup>2-</sup> is green while MnO<sub>4</sub><sup>-</sup> is pink. Ozone oxidises  $MnO_4^{2-}$  to  $MnO_4^{-}$ .

- 9. An oxide of a non-metal has the following properties:
  - (i) acts both as a proton donor as well as proton acceptor
  - (ii) it reacts readily with basic and acidic oxides
  - (iii) it oxidises Fe at its boiling point.

The oxide is:

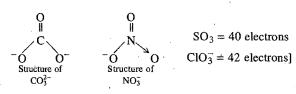

(a)  $P_2O_5$ 

(b) SiO<sub>2</sub>

(c) H<sub>2</sub>O

- (d) CO<sub>2</sub>
- 10. Oxygen is more electronegative than sulphur, yet H<sub>2</sub>S is acidic in nature while H<sub>2</sub>O is neutral because:
  - (a) water molecules are associated due to intermolecular hydrogen bonding
  - (b) water has higher boiling point than H<sub>2</sub>S
  - (c) H—S is weaker than O—H bond
  - (d) H<sub>2</sub>S is a gas at ordinary temperature while H<sub>2</sub>O is a liquid
- 11. Which of the following are isoelectronic and isostructural?
  - (a)  $NO_3^-, CO_3^{2-}$
- (b) SO<sub>3</sub>, NO<sub>3</sub><sup>-</sup> (d) CO<sub>3</sub><sup>2-</sup>, SO<sub>3</sub>
- (c)  $ClO_3^-, CO_3^{2-}$

[Hint:  $NO_3^-$  and  $CO_3^{2-}$  both have same number of electrons (32) electrons) and central atom in each being sp<sup>2</sup> hybridized.

- 12. O<sub>3</sub> cannot oxidise:
  - (a) KI
- (b) FeSO<sub>4</sub>
- (c) KMnO<sub>4</sub>
- (d)  $K_2MnO_4$
- 13. Which of the following is/are correct?
  - (a)  $O_3$  + moist iodine  $\longrightarrow$  HIO<sub>3</sub>
  - (b)  $FeCl_3 + H_2S \longrightarrow colloidal sulphur$
  - (c)  $O_3 + Ag \longrightarrow black silver$
- 14. A black sulphide when treated with ozone becomes white. The white compound is:
  - (a) ZnSO<sub>4</sub>
- (b) PbSO<sub>4</sub>
- (c) BaSO<sub>4</sub>
- (d) CaSO<sub>4</sub>
- [Hint: PbS  $\xrightarrow{O_3}$  PbSO<sub>4</sub>]
- White 15. Which of the following is correct structure of S<sub>2</sub>Cl<sub>2</sub>?

(a) 
$$S = S < \frac{Cl}{Cl}$$

- 16. What is the hybrid state and oxidation state of sulphur in Caro's acid?
  - (a)  $sp^2$ , +10 (c)  $sp^2$ , +6

[Hint: The structure of Caro's acid is

HO—S—O—O—H. The hybrid state is 
$$sp^3$$
 and its O

O.N. is +6.

- 17. Identify the correct sequence of increasing number of  $\pi$ -bonds in structures of the following molecules.
  - (i)  $H_2S_2O_6$  (ii)  $H_2SO_3$  (iii)  $H_2S_2O_5$
  - (a) I, II, III
- (b) II, III, I
- (c) II, I, III
- (d) I, III, II

$$H_2SO_3$$
, HO—S—OH—one π-bond;

- **18.** Sulphur reacts with chlorine in 1:2 ratio and forms (X). (X)on hydrolysis gives a sulphur compound (Y). What is the hybridized state of central atom in the anion of (Y)?
  - (a) sp (c) sp<sup>2</sup>

(b)  $sp^3$ 

[Hint:  $S + 2Cl_2 \longrightarrow SCl_4$ ;

$$\begin{array}{c} SCl_4 + 4H_2O \longrightarrow & S(OH)_4 + 4HCl \\ \downarrow \\ & H_2SO_3 + H_2O \\ (Y) \end{array}$$

The hybridized state of S in (Y) is  $sp^3$ .

9. (c)

- **1.** (a)
- 2. (a)
- 3. (b)

13. (d) 17. (b) 15. (c) 16. (d) 18. (b)

# **Assertion-Reason Type Questions**

The following questions consist of two statements as Assertion (A) and Reason (R). Examine the statements and answer the questions according to following instructions:

Mark (a) if both (A) and (R) are correct and (R) is the correct explanation of (A).

Mark (b) if both (A) and (R) are correct but (R) is not the correct explanation of (A).

Mark (c) if (A) is correct but (R) is wrong.

- Mark (d) if (A) is wrong but (R) is correct.
- Mark (e) if both (A) and (R) are wrong.

- 1. (A) Tailing of mercury occurs on passing O<sub>3</sub> through it.
  - (R) This is due to oxidation of mercury. [A.I.I.M.S. 1999]
- 2. (A) H<sub>2</sub>O is the only hydride of the chalcogens which is
  - (R) In ice, each O atom is surrounded by 4H atoms.
- 3. (A) Ozone is a powerful oxidising agent in comparison to
  - (R) Ozone is diamagnetic while O<sub>2</sub> is paramagnetic.

[A.I.I.M.S. 2005]

- 4. (A) SeCl<sub>4</sub> does not have a tetrahedral structure.
  - (R) Se in SeCl<sub>4</sub> has two lone pairs.
- [A.I.I.M.S. 2005]

- 5. (A) H<sub>2</sub>SO<sub>4</sub> forms only one series of salts.
  - (R) The molecule of H<sub>2</sub>SO<sub>4</sub> consists of only one OH group.
- 6. (A) SO<sub>3</sub> acts as an oxidising as well as a reducing agent.
  - (R) SO<sub>2</sub> acts as an oxidising as well as a reducing agent.

## Answers

# THOUGHT TYPE QUESTIONS

### **THOUGHT 1**

Sulphuric acid is considered as the king of chemicals. The prosperity of any country is measured by the amount of sulphuric acid it consumes. Sulphuric acid is, thus, a substance of very great commercial importance as it is used practically in every important industry. This is due to the following properties of sulphuric acid:

- (a)-acidic-nature
- (b) oxidising nature
- (c) dehydrating nature
- (d) sulphonation
- 1. Sulphuric acid has very corrosive action on skin because:
  - (a) it reacts with proteins
  - (b) it acts as an oxidising agent
  - (c) it acts as a dehydrating agent
  - (d) it acts as a dehydrating agent and absorption of water is highly exothermic.
- 2. Which of the following reactions depict the oxidising behaviour of  $H_2SO_4$ ?
  - (a)  $2HI + H_2SO_4 \longrightarrow I_2 + SO_2 + 2H_2O$
  - (b)  $NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl$
  - (c)  $2\text{NaOH} + \text{H}_2\text{SO}_4 \longrightarrow \text{Na}_2\text{SO}_4 + 2\text{H}_2\text{O}$
  - (d)  $2PCl_5 + H_2SO_4 \longrightarrow 2POCl_3 + 2HCl + SO_2Cl_2$
- 3. Sulphuric acid is used:
  - (a) in lead storage batteries (b) in making fertilizers
  - (c) in making explosives
- (d) in all of these
- **4.** The formation of nitroglycerine is done by the use of concentrated nitric acid and concentrated sulphuric acid. The process of conversion of glycerine into nitroglycerine is termed as:
  - (a) sulphonation
- (b) oxidation
- (c) nitration
- (d) dehydration
- 5. Only carbon is obtained when concentrated H<sub>2</sub>SO<sub>4</sub> is added to:
  - (a) formic acid
- (b) cane sugar
- (c) oxalic acid
- (d) ethyl alcohol
- **6.** Concentrated H<sub>2</sub>SO<sub>4</sub> cannot be used to prepare **HBr** or **HI** from KBr or KI because it:
  - (a) reacts too slowly with KBr or KI
  - (b) reduces HBr or HI
  - (c) oxidises HBr or HI
  - (d) oxidises KBr to KBrO<sub>3</sub> or KI to KIO<sub>3</sub>

### **THOUGHT 2**

The binary compounds of oxygen with other elements are called oxides. They are classified either depending upon their acid-base characteristics or on the basis of oxygen content.

- (a) Normal oxides: These oxides which contain oxygen atoms as permitted by the normal oxidation number, i.e.,
   -2. Normal oxide may be acidic, basic, amphoteric or neutral.
- **(b) Polyoxides:** The oxides which contain oxygen atoms different than those permitted by the normal oxidation number of -2.
  - (i) **Peroxides:** Two oxygen atoms are linked to each other and each oxygen has -1 oxidation number. They contain (O—O)<sup>2-</sup> unit.
  - (ii) Superoxides: These oxides contain  $(O-O)^{-1}$  unit, *i.e.*, each O-atom has oxidation number -1/2.
- (c) Suboxides: These contain low content of oxygen than expected.
- (d) Mixed oxides: These oxides are made of two simpler oxides.
- 1. Which pair of species is referred to as suboxides?
  - (a) CO, NO
- (b) SO<sub>2</sub>, CaO
- (c) N<sub>2</sub>O, CO
- (d)  $N_2O$ ,  $C_3O_2$
- 2. Which of the following pairs contains neutral oxides?
  - (a)  $SO_2$ ,  $SO_3$
- (b)  $N_2O_3, N_2O_5$
- (c) CO, NO
- (d) Na<sub>2</sub>O, CaO
- 3. Which of the following pairs contains mixed oxides?
  - (a)  $Pb_3O_4$ ,  $Fe_3O_4$
- (b) MnO<sub>2</sub>, BaO<sub>2</sub>
- (c)  $KO_2$ ,  $Na_2O_2$
- (d)  $Mn_3O_4$ ,  $N_2O_5$
- 4. Which of the following pairs contains amphoteric oxides ?
  - (a) BeO, BaO
- (b) BeO,  $Al_2O_3$
- (c)  $Al_2O_3$ ,  $P_2O_5$
- (d) FeO, CuO
- 5. Which of the following oxides is paramagnetic in nature?
  - (a) KO<sub>2</sub>

(b) BaO<sub>2</sub>

(c) H<sub>2</sub>O

(d) CO<sub>2</sub>

## THOUGHT 3

Sulphur and rest of the elements of group 16 are less electronegative than oxygen. Therefore, their atoms cannot take up electrons easily. They can acquire  $ns^2np^6$  configuration by sharing two electrons with the atoms of other elements and thus, exhibit +2 oxidation state in their compounds. In addition to this, their

atoms have vacant d-orbitals in their valence shell to which electrons can be promoted from the p and s-orbitals of the same shell. As a result, they can show +4 and +6 oxidation states.

- 1. The oxidation state of sulphur in  $S_8$ ,  $SO_3$  and  $H_2S$  respectively are:
  - (a) 0, +6 and -2
- (b) +2, +6, -2
- (c) 0, +4 and +2
- (d) -2, +6, +2
- 2. The oxidation state of sulphur in Na<sub>2</sub>S<sub>4</sub>O<sub>6</sub> is:
  - (a) 2/3

(b) 3/2

(c) 3/5

- (d) 5/2
- 3. The nature of the compounds of sulphur having +4 oxidation state is:
  - (a) act as oxidising agents
  - (b) act as reducing agents

- (c) act as oxidising as well as reducing agents
- (d) cannot be predicted
- **4.** Like sulphur, oxygen does not show +4 and +6 oxidation states. The reason is:
  - (a) that oxygen is a gas while sulphur is a solid
  - (b) that oxygen has high ionisation enthalpies in comparison to sulphur
  - (c) that oxygen has high electron affinity in comparison to sulphur
  - (d) that oxygen has no d-orbitals in its valence shell.
- 5. Oxygen exhibits +2 oxidation state in:
  - (a) H<sub>2</sub>O

(b) OF<sub>2</sub>

(c) Cl<sub>2</sub>O

(d) H<sub>2</sub>O<sub>2</sub>

Thought 1	1. (d)	2. (a)	3. (d)	<b>4.</b> (c)	<b>5.</b> (b)	<b>6.</b> (c
Thought 2	<b>1.</b> (d)	2. (c)	3. (a)	<b>4.</b> (b)	<b>5.</b> (a)	
Thought 3	1. (a)	2. (d)	3. (c)	<b>4.</b> (d)	5, (b)	

## INTEGER ANSWER Type Questions

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. The number of unpaired electrons in the valence shell of the members of oxygen family is:
- 2. What is oxidation state of sulphur in Caro's acid?
- 3. How many orbitals are involved in the hybridisation of sulphur in SCl<sub>2</sub>?
- 4. How many  $\pi$ -bonds are present in Marshall's acid?
- 5. Ozone reacts with dry iodine to form an oxide having . . . . oxygen atoms in its molecule.
- **6.** How many lone pairs are present in OF<sub>2</sub> molecule?

## Answers

1. (2) Valence shell has six electrons. Out of which two are unpaired.

$$\uparrow \downarrow \qquad \uparrow \downarrow \qquad \uparrow \qquad \uparrow$$

2. (6) 
$$H - O - S_{+6} - O - O - H$$

3. (4)  $sp^3$ -hybridisation

- 4. (4) HO S O O S OH  $\parallel 1 \parallel 2 \parallel 1 \parallel 4$   $\downarrow 1 \parallel 2 \parallel 1 \parallel 4$
- 5. (9)  $9O_3 + 2I_2 \longrightarrow I_4O_9 + 9O_2$

# CHAPTER 12

## Elements of Group VIIA or 17

(Halogens)

### Contents:

- 12.1 Position in Periodic Table
- 12.2 Anomalous Behaviour of Fluorine
- 12.3 Fluorine
- 12.4 Chlorine
- 12.5 Bromine
- **12.6** Iodine
- 12.7 Halogen Acids or Hydracids
- 12.8 Oxides of Chlorine
- 12.9 Oxy-Acids of Chlorine
- 12.10 Interhalogen Compounds
- 12.11 Polyhalides
- 12.12 Basic Properties of Iodine
- 12.13 Pseudohalides and Pseudohalogens

### 12.1 POSITION IN PERIODIC TABLE

17th or VIIA group of the periodic table (extended form) consists of five elements; fluorine (F), chlorine (Cl), bromine (Br), iodine (I) and astatine (At). This group of five elements forms a family known as halogen family as their salts are found in sea water. Halogen is a Greek word meaning a sea salt. Halogens are p-block elements as the last differentiating electron is accommodated on np subshell. These elements have seven electrons in their valency shell and thus placed in VII group of the periodic table.

Group Period	VIA 16	- VIIA 17	Zero 18
-		H*	He
. 1		(1)	(2)
_	0	F	Ne
2	(8)	(9)	(10)

	Se	Br	Kr
4	(34)	(35)	(36)
_	Te	· I	Xe
5	(52)	(53)	(54)
_	Po	At	Rn
6	(84)	(85)	(86)
_	Uuh		Uuo
7	(116)	?	(118)

Except astatine, the members are found in combined state in considerable quantities in nature. Astatine is unstable element of radioactive origin. Astatine is radioactive artificially prepared element. These elements possess same electronic configuration and show similarities as well as gradual gradation in their physical and chemical properties. Thus, the inclusion of these elements in the same subgroup is justified. However, like other groups, the first element fluorine differs from other elements of the group in some respects.

### 1. Electronic Configuration

The electronic configurations of halogens are given as:

Element	At. No.		Electronic configuration	With inert gas core
Fluorine	9	2, 7	$1s^2$ , $2s^2 2p^5$	[He] $2s^22p^5$
Chlorine	17	2, 8, 7	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^5$	[Ne] $3s^23p^5$
Bromine	35	2, 8, 18, 7	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^5$	[Ar] $3d^{10}$ , $4s^24p^5$
Iodine	53	2, 8, 18, 18, 7	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}$ , $5s^2$ $5p^5$	[Kr] $4d^{10}$ , $5s^25p^5$
Astatine	85	2, 8, 18, 32, 18, 7	$1s^2$ , $2s^2$ $2p^6$ , $3s^2$ $3p^6$ $3d^{10}$ , $4s^2$ $4p^6$ $4d^{10}4f^{14}$ , $5s^2$ $5p^6$ $5d^{10}$ , $6s^2$ $6p^5$	[Xe] $4f^{14}$ , $5d^{10}$ , $6s^26p^5$

Note: The last member of group 17 or VIIA with atomic number 117 (ununseptium) is yet to be discovered.

<sup>\*</sup>Sometimes hydrogen, the lightest element, is also included in group VIIA or 17.

All the halogens have seven electrons  $(ns^2np^5)$  in their outermost shell. The electrons in np-orbitals are distributed as  $np_x^2$ ,  $np_y^2$ ,  $np_z^1$ . The penultimate shell in F has 2 electrons, in Cl 8 electrons and in Br, I and At 18 electrons. This shows why fluorine differs from chlorine and these two differ from the remaining elements.

Since the halogens have only one electron less than the number present in the adjacent noble gas, they have a tendency to take up one electron to acquire the stable noble gas configuration. Hence, the halogens are very reactive elements.

### 2. Physical Characteristics

(a) Physical state: The tendency to form condensed molecules increases with increase in atomic number. Fluorine and chlorine are gases at ordinary temperature, bromine is a highly fuming liquid while iodine is a volatile solid.

F	Cl	Br	I
Gas	Gas	Fuming liquid	Volatile solid

Halogens exist as diatomic covalent molecules. These molecules are held together by weak van der Waals' forces. On account of weak intermolecular forces, the halogens are volatile in nature. With the increase in size, these forces increase from fluorine to iodine and hence change in physical state occurs from gas  $(F_2 \text{ and } Cl_2)$  to solid  $(I_2)$ .

(b) Atomic and ionic radii: The halogens have the lowest values of atomic radii in their respective periods. This is due to maximum effective nuclear charge of the halogen in its respective period. However, the atomic radii and ionic radii  $(X^-)$  ion) increase gradually from fluorine to iodine.

Element	F	Cl	Br	I
Atomic radii (pm)	64	99	114	133
Ionic radii (pm) (X <sup>-</sup> )	133	184	196	220
	Increase gradually			

As we move from fluorine to astatine, an extra shell of electrons is added to each element. The addition of an extra shell increases the atomic and ionic radii from fluorine to astatine. The radius of the halide ion is always greater than the corresponding halogen atom.

(c) Atomic volume and density: These increase steadily from fluorine to iodine.

Element	F	CI	Br	I	
At. volume (mL)	17.1	18.7	23.5	25.7	
Density (in liquid state)	1.5	1.66	3.19	4.94 (solid)	
$(g cm^{-3})$	at 85 K	at 203 K	at 273 K	at 293 K	
	Increase gradually				

(d) Energy and stability of X—X bond: With the increase of size, the bond length increases from fluorine to iodine. Since the bond length of fluorine is minimum, its bond dissociation energy should be highest. However, the bond dissociation energy of fluorine is less than Cl—Cl and Br—Br.

Actually, the bond dissociation energy should have decreased from fluorine to iodine but it starts decreasing from chlorine to iodine.

X— $X$ bond	FF	Cl—Cl	BrBr	I—I
Bond length (pm)	142	199	228	267
Bond dissociation	158.8	242.6	192.8	151.1
energy (kJ/mol)				

It has been suggested by Coulson that the lower value of bond dissociation energy of fluorine is due to the high interelectronic repulsions between non-bonding electrons in the 2p-orbitals of fluorine. As a result, F—F bond is weaker in comparison to Cl—Cl and Br—Br bonds. Thus, the bond dissociation energy follows the sequence:

$$Cl_2 > Br_2 > F_2 > I_2$$

(e) Ionisation enthalpy: The ionisation enthalpies of halogens are very high. This indicates that the halogens have a little tendency to lose electron to form  $X^+$  cation. However, the ionisation enthalpies decrease from F to I, *i.e.*, the tendency to form cation increases from F to I as the size of halogen increases.

Element	F	Cl	Br	I
First ionisation	1680	1256	1142	1008
enthalpy (kJ mol <sup>-1</sup> )		Decreases	gradually	·.

Iodine having the lowest value of ionisation potential has some tendency to form I<sup>+</sup> ion as it forms compounds like ICl, ICN, etc., which in molten state conduct electricity showing the existence of I<sup>+</sup> cation.

**(f) Electron affinity:** Electron affinity values are high in the case of halogens as they have one electron less than the nearest noble gas configuration, and have a strong tendency to accept an additional electron.

The low value of electron affinity of fluorine is probably due to small size of fluorine atom, *i.e.*, electron density is high which hinders the addition of an extra electron. As we move down from chlorine onwards, the electron affinity values become less and less negative as the size of the halogen increases. Thus, electron affinity follows the sequence:

Cl (-349 kJ 
$$\text{mol}^{-1}$$
) > F (-333 kJ  $\text{mol}^{-1}$ ) > Br (-325 kJ  $\text{mol}^{-1}$ ) > I (-296 kJ  $\text{mol}^{-1}$ )

(g) Electronegativity: The halogens have high values of electronegativities. Fluorine has the maximum electronegativity. The electronegativity decreases from fluorine to iodine.

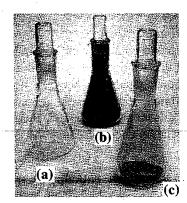

As a result of the decrease of electronegativity, the non-metallic character decreases from fluorine to iodine. Metallic

character is observed in iodine as it forms in a few cases a positive ion and has a metallic lustre.

**(h) Colour:** All the halogens are coloured. The colour deepens with the rise of atomic number from fluorine to iodine.

The colour is due to the absorption of energy from visible light by their molecules for excitation of outer electrons to higher energy levels. Fluorine absorbs violet portion of the light and thus appears yellow while iodine absorbs yellow and green portions of the light and thus appears violet.

Change in colour on moving down this group is called blue shift or bathochromic shift.

Colour of Halogens

- (a) Colour of Chlorine (Cl<sub>2</sub>)—Yellow green
- (b) Colour of Bromine (Br<sub>2</sub>)—Reddish brown
- (c) Iodine (I2)-Deep violet

Fig. 12.1

(i) Oxidation states: Since these elements have seven electrons in their valency shell, each element tries to attain 8 electrons either by accepting an electron from an element which is less electronegative than it or by sharing its unpaired electron in p-orbital with another element. When the halogen atom combines with an element of lesser electronegativity, it shows -1 oxidation state. On the other hand, when it combines with an element having higher electronegativity, it exhibits +1 oxidation state. Fluorine, being the most electronegative, always shows -1 oxidation state only.

Chlorine, bromine and iodine show positive oxidation states as the electrons in the valency shell can be promoted to vacant d-orbitals. These elements (*i.e.*, Cl, Br and I) can show +3, +5 and +7 oxidation states depending on the number of singly occupied orbitals, *i.e.*, oxidation states lie between -1 to +7.

Halogen atom  $\uparrow\downarrow\uparrow\uparrow\downarrow\uparrow\uparrow$ (except F atom) in the ground state. 1 unpaired electron; -1 or +1  $(ns^2np^5)$ oxidation state Halogen atom in the first excited state.  $(ns^2np^4nd^1)$ 3 unpaired electrons; +3 oxidation state Halogen atom in the  $|\uparrow\downarrow\downarrow|$   $|\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow\uparrow$ second excited state.  $(ns^2np^3nd^2)$ 5 unpaired electrons; +5 oxidation state ndHalogen atom in the  $|\uparrow|\uparrow|\uparrow|\uparrow|\uparrow|\uparrow|\uparrow|\uparrow$ third excited state.  $(ns^1np^3nd^3)$ 7 unpaired electrons; +7 oxidation state F atom has no d-orbitals in the valency shell, thus it cannot have any excited state and consequently cannot show any of the higher oxidation states. In the case of bromine, the penultimate shell (i.e.,  $3s^23p^63d^{10}$ ) is weakly screening and hence the energy required to promote an electron from 4s-orbital is higher than in chlorine and thus bromine does not show +7 oxidation state.

Besides +3, +5 and +7 oxidation states, +4 and +6 oxidation states are also shown by these elements in oxides and oxyacids.

### **Examples:**

Oxidation state	Fluorine	Chlorine.	Bromine	Iodine
-1	NaF, OF <sub>2</sub> ,	NaCl, MgCl <sub>2</sub> ,	NaBr, CaBr <sub>2</sub> ,	NaI, AgI,
	ClF <sub>3</sub> ,IF <sub>5</sub>	AgCl, HCl	AgBr, HBr	HI, CaI <sub>2</sub>
+1	×	HClO, Cl <sub>2</sub> O	HBrO, Br <sub>2</sub> O	HIO, ICl
+3	×	CIF <sub>3</sub> , HClO <sub>2</sub>	BrF <sub>3</sub>	ICl <sub>3</sub>
+4	×	ClO <sub>2</sub>	BrO <sub>2</sub>	$I_2O_4$
+5	- x	HClO <sub>3</sub>	HBrO <sub>3</sub> , BrF <sub>5</sub>	HIO <sub>3</sub> , IF <sub>5</sub>
+6	×	Cl <sub>2</sub> O <sub>6</sub>	BrO <sub>3</sub>	×
+7	×	HClO <sub>4</sub>	×	HIO <sub>4</sub> , IF <sub>7</sub>

(j) Reduction potentials and oxidising nature: Standard reduction potentials of halogens are positive and decrease from fluorine to iodine. Thus, halogens act as strong oxidising agents and their oxidising power decreases from fluorine to iodine.

Element F Cl Br I

Reduction potential

(
$$E^{\circ}$$
 volt) +2.87 +1.36 +1.09 +0.54

Decreases gradually

Oxidising nature also decreases

The strength of an oxidising agent depends on several energy terms as shown below:

$$\frac{1}{2}X_{2}(\text{solid}) \xrightarrow{\frac{1}{2}\text{heat of}} \frac{1}{2}X_{2}(\text{liq.}) \xrightarrow{\frac{1}{2}\text{heat of}} \underbrace{\frac{1}{2}X_{2}(\text{gas})} \xrightarrow{\frac{1}{2}\text{heat of}} X(\text{gas})$$

$$\downarrow \text{Oxid.} \quad \text{Electron} \quad \text{potential} \quad \text{Effinity} \downarrow$$

$$X^{-}(\text{hyd.}) \xleftarrow{\text{Heat of}} X^{-}(\text{gas})$$

$$E = \frac{1}{2}H_f + \frac{1}{2}H_{ev} + \frac{1}{2}H_d$$
 - electron affinity -  $H_{hyd}$ .

The E values decreases from fluorine to iodine.

Fluorine is the strongest oxidising agent. It will oxidise other halide ions to halogens in solution or when dry.

F<sub>2</sub> + 2
$$X^ \longrightarrow$$
 2F<sup>-</sup> +  $X_2$   
( $X^-$  = Cl<sup>-</sup>, Br<sup>-</sup> or I<sup>-</sup>)

Similarly, chlorine will oxidise  $Br^-$  and  $I^-$  solution to  $Br_2$  and  $I_2$ , respectively and  $Br_2$  will oxidise  $I^-$  to  $I_2$ . In general, a

halogen of low atomic number will oxidise the halide ion of higher atomic number.

The halide ions act as reducing agents. F ion does not show any reducing nature but Cl, Br and I ion act as reducing agents and their reducing nature is in increasing order.

$$\xrightarrow{\text{CI}^-} \xrightarrow{\text{Br}^-} \xrightarrow{\text{I}^-}$$
Reducing nature increases

**(k) Solubility:** Halogens, being non-polar molecules, do not dissolve to a considerable extent in a polar solvent like water. However, fluorine reacts with water readily forming a mixture of oxygen and ozone.

$$2F_2 + 2H_2O \longrightarrow 4HF + O_2$$
  
 $3F_2 + 3H_2O \longrightarrow 6HF + O_3$ 

C1<sub>2</sub>, Br<sub>2</sub> and I<sub>2</sub> are more soluble in organic solvents such as CCl<sub>4</sub>, CHCl<sub>3</sub>, paraffins and produce coloured solutions. Chlorine, bromine and iodine give yellow, brown and violet colour, respectively, in chloroform or carbon tetrachloride. It is believed that in non-polar solvents halogens exist as free molecules.

In nucleophilic solvents like alcohols, ketones, liquid sulphur dioxide, halogens produce brown solutions. It is due to complex formation (solvent  $\rightarrow$  halogen).

### 3. Chemical Characteristics

(a) **Reactivity:** Halogens are most reactive non-metallic elements, high reactivity is due to low dissociation energies of the halogen molecules and high electron affinities.

Molecule 
$$N_2$$
  $O_2$   $H_2$   $X_2$  (halogen) Dissociation energy 225 118.3 103.2 35.5 to 57.2 (kcal/mol)

In halogens, fluorine is most reactive and iodine is least reactive.

This is due to following factors:

- (i) As the size increases, the attraction for an additional electron by the nucleus becomes less. Thus, reactivity decreases.
- (ii) Due to decrease in electronegativity from F to I, the bond between halogen and other elements becomes weaker and weaker. Fluorides are most stable while iodides are least.
  - (iii) Dissociation energies of X—X bonds are low.

The following reactions illustrate the relative reactivity of halogens.

(i) Reaction towards water: Fluorine decomposes water very readily even at low temperature and in dark forming mixture of O<sub>2</sub> and O<sub>3</sub>, Cl<sub>2</sub> decomposes water in presence of sunlight while bromine decomposes water very slowly in presence of sunlight. Iodine does not decompose water.

$$\begin{array}{c} X_2 + \text{H}_2\text{O} & \xrightarrow{\text{Sunlight}} & \text{H}X + \text{H}X\text{O} \\ \text{(C1}_2 \text{ or } \text{Br}_2\text{)} & & \text{3F}_2 + 3\text{H}_2\text{O} & \longrightarrow & \text{6HF} + \text{O}_3 \\ 2\text{F}_2 + 2\text{H}_2\text{O} & \longrightarrow & \text{4HF} + \text{O}_2 \\ \text{I}_2 + \text{H}_2\text{O} & \longrightarrow & \text{No reaction} \end{array}$$

(ii) Reaction with metals and non-metals: Nearly all metals combine with fluorine either in cold or on heating forming fluorides. Chlorine combines with large number of metals but

slowly. Bromine and iodine do not react with noble metals like Au, Pt and even with less active metals.

Halogens also combine with a number of non-metals like S, P, As, etc. The reactivity decreases from fluorine to chlorine. For example, sulphur forms hexafluoride with fluorine (SF<sub>6</sub>), tetrachloride with chlorine (SCl<sub>4</sub>) and dibromide with bromine (SBr<sub>2</sub>) and there is no reaction between sulphur and iodine.

(iii) Reaction with hydrocarbons: Fluorine brings decomposition of the hydrocarbon and also forms fluorinated products readily.

$$CH_4 + 2F_2 \longrightarrow C + 4HF$$

Chlorine and bromine give substitution reactions. The rates of reactions with bromine are slow. Iodine has practically no action on hydrocarbons.

$$CH_4 + Cl_2 \longrightarrow CH_3Cl \xrightarrow{Cl_2} CH_2Cl_2 \xrightarrow{Cl_2} CHCl_3 \xrightarrow{Cl_2} CCl_4$$

**(b) Hydrides of the halogens (Hydrogen halides):** All the halogens react with hydrogen to form volatile covalent hydrides of formula HX. These hydrides are called hydracids. The activity of halogens towards hydrogen decreases from fluorine to iodine.

Hydrogen combines explosively with fluorine even in dark. It combines with chlorine in presence of sunlight and with bromine on heating. Hydrogen combines with iodine on heating and in presence of a catalyst. The reaction with iodine is reversible and incomplete. Detailed discussion is given in section 12.7.

(c) Oxides: The compounds of oxygen and fluorine are not called as oxides but oxygen fluorides as fluorine is more electronegative than oxygen. The compounds of oxygen and rest of the halogens are termed oxides. Halogens and oxygen do not combine directly with each other. However, these compounds have been obtained indirectly. The known compounds are:

$$\begin{array}{cccc} OF_2 & Cl_2O & Br_2O & I_2O \\ O_2F_2 & ClO_2 & BrO_2 \\ & Cl_2O_6 & BrO_3 \\ & Cl_2O_7 & \end{array}$$

In these oxides, bonds are mainly covalent due to small difference in the electronegativity of oxygen and the halogens. Oxygen fluorides do not form oxyacids. Oxides of chlorine are acidic and the acidic nature increases as % of oxygen increases. Thus, Cl<sub>2</sub>O is least acidic while Cl<sub>2</sub>O<sub>7</sub> is most acidic oxide.

$$Cl_2O + H_2O \Longrightarrow 2HClO$$
  
 $2ClO_2 + H_2O \longrightarrow HClO_2 + HClO_3$   
 $Cl_2O_6 + H_2O \longrightarrow HClO_3 + HClO_4$   
 $Cl_2O_7 + H_2O \longrightarrow 2HClO_4$ 

The oxides of bromine and iodine are also acidic in nature. All the three monoxides, viz., OF<sub>2</sub>, Cl<sub>2</sub>O and Br<sub>2</sub>O have tetrahedral structure involving  $sp^3$  hybridization of oxygen; bond angle increases with increase in size of halogen atom.

(d) Oxyacids:	Fluorine does not form any oxyacid as it is more electronegative than oxygen. Other halogens form oxyacids
of the type $HXO$ , I	HXO <sub>2</sub> , HXO <sub>3</sub> and HXO <sub>4</sub> . Some of the acids are quite unstable and are known only in solutions or as their
salts. List of oxyac	eids is given below:

Oxidation number	Oxyacids of					a		
of halogen	Cl	Br	,I	General name	Acidity	Stability	Oxidising nature	
+1	HClO	HBrO	HIO	Hypo-halous	. 1		1.0	
+3	HClO <sub>2</sub>			Halous	ases	ases	creases	
+5	HClO <sub>3</sub>	HBrO <sub>3</sub>	HIO <sub>3</sub>	Halic	Incre	Incre	Decr	
+7	HClO <sub>4</sub>		HIO <sub>4</sub> (H <sub>5</sub> IO <sub>6</sub> )	Perhalic		1	1	

Acidity decreases ----

Note: Greater is the oxidation state of central halogen atom more will be the acidic character.

### General properties

- (i) In oxyacids, the hydrogen is a part of an —OH group and not directly attached to the halogen atom. The oxyacids are monobasic and form one series of salts.
- (ii) In oxyacids of the same halogen in different oxidation states, the acidic nature and thermal stability increase while oxidising nature decreases with the increase of oxidation state of the halogen. For example, for the four oxyacids of chlorine, the acidic character and thermal stability are in the order:

while the oxidising power is in the order:

$$HCIO > HCIO_2 > HCIO_3 > HCIO_4$$

- i.e., increasing oxygen content leads to:
- (a) an increase in thermal stability
- (b) an increase in strength of the acid
- (c) a decrease in oxidising power.
- (iii) In the oxyacids of different halogens in the same oxidation state, the thermal stability and acidic nature, in general, decrease with increase of atomic number. However, in HXO<sub>3</sub>, HIO<sub>3</sub> is most stable.
- **(e) Reaction with alkalies:** Fluorine reacts with cold dilute alkalies yielding OF<sub>2</sub> (oxygen difluoride) and with conc. alkalies evolve oxygen.

$$\begin{array}{ccc} 2NaOH + 2F_2 & \longrightarrow & 2NaF + OF_2 + H_2O \\ \text{(Cold and dilute)} \end{array}$$

$$4NaOH + 2F_2 \longrightarrow 4NaF + O_2 + 2H_2O$$

Cl<sub>2</sub>, Br<sub>2</sub> and I<sub>2</sub> behave similarly but differently than fluorine, with cold dilute alkalies, they form a mixture of halide and hypohalite and with concentrated hot alkalies a mixture of halide and halate.

2NaOH + Cl<sub>2</sub> 
$$\longrightarrow$$
 NaCl + NaClO + H<sub>2</sub>O Sodium Sodium chloride hypochlorite

$$\begin{array}{cccc} 6\text{NaOH} + 3X_2 & \longrightarrow & 5\text{Na}X + \text{Na}X\text{O}_3 + 3\text{H}_2\text{O} \\ \text{Hot and conc.} & \text{Halide} & \text{Halate} \\ \hline & 6\text{NaOH} + 3I_2 & \longrightarrow & 5\text{NaI} + \text{NaIO}_3 + 3\text{H}_2\text{O} \\ \hline & & \text{Sod. iodide Sod. iodate} \\ \end{array}$$

(f) Interhalogen compounds: The halogens on account of difference in their electronegativities combine with each other to form compounds of type  $AB_n$  where A is always bigger atom and B is smaller atom and 'n' may have values 1, 3, 5 and 7. These are covalent compounds and called interhalogen compounds. The value of 'n' increases with the increase of size of halogen A. Maximum value of 'n' for chlorine is 3, for bromine 5 and for iodine 7. The known interhalogen compounds are listed below:

AB type : CIF, BrF, BrCl, ICl, IBr  $AB_3$  type : CIF<sub>3</sub>, BrF<sub>3</sub>, ICl<sub>3</sub>  $AB_5$  type : IF<sub>5</sub>, BrF<sub>5</sub>  $AB_7$  type : IF<sub>7</sub>

The interhalogen compounds are gases or liquids. These are volatile and fume in air. In general, these compounds are more reactive than pure halogens except fluorine because A—B bond is weaker than B—B bond. These are hydrolysed and act as oxidising agents. The compounds of iodine and fluorine are thermally more stable while the compounds of iodine and chlorine or iodine and bromine are less stable.

# 12:2\* ANOMALOUS BEHAVIOUR OF FLUORINE

Fluorine differs from other members of its own sub-group due to the following reasons:

- (i) Small size of the atom in comparison to the sizes of Cl, Br and I atoms.
  - (ii) Highest electronegativity.
  - (iii) Absence of *d*-orbitals in its valency shell.
  - (iv) Highest positive reduction potential.

The main points of difference are:

(1) Fluorine shows only a negative oxidation state of -l due to maximum value of electronegativity. It never shows any

positive oxidation state. The other halogens show negative as well as positive oxidation states, *i.e.*, between -1 and +7.

- (2) Fluorine is most reactive as bond dissociation energy of F—F bond is low. X—X bond is stronger in Cl<sub>2</sub> and Br<sub>2</sub>.
- (3) Maximum covalency of fluorine is one as there is no d-orbital in its valency shell. Other members can have maximum covalency of 7 because of vacant d-orbitals.
- (4) HF is a weak acid in comparison to HCl, HBr and HI under similar circumstances. HF is a liquid (b.pt. 19°C) while HCl, HBr and HI are gases under ordinary conditions. This is due to presence of hydrogen bonding in HF while hydrogen bonding is not present in HCl, HBr and HI.
- (5) Hydrofluoric acid is a dibasic acid  $(H_2F_2)$  while HCl, HBr and HI are monobasic in nature. Thus, hydrofluoric acid forms two series of salts such as NaHF<sub>2</sub>, Na<sub>2</sub>F<sub>2</sub>. Most of the fluorides are ionic. These contain  $F^-$  ion while other halides have frequently molecular lattices.
- (6) AgF is soluble in water while AgCl, AgBr and AgI are insoluble in water. Similarly, calcium fluoride is insoluble and other halides of calcium are soluble.
- (7) Fluorine combines with sulphur to form SF<sub>6</sub> but no other halogen forms the hexahalide with sulphur.
- (8) Fluorine does not form any oxyacid but other halogens form a number of oxyacids.
- (9) It directly combines with carbon while other halogens do not react even under drastic conditions.
- (10) Ozone is formed when fluorine decomposes water. Ozone is not formed when other halogens react with water.
- (11) Fluorine does not form any oxysalt when it reacts with alkalies while other halogens form oxysalts with alkalies.
- (12) Fluorides are more stable than corresponding chlorine compounds. For example, UF<sub>6</sub> is more stable than UCl<sub>6</sub>. NF<sub>3</sub> is non-explosive while NCl<sub>3</sub> is highly explosive.
- (13) The fluoride ion has a great tendency to form complex ions, e.g.,  $[AIF_6]^{3-}$ ,  $[FeF_6]^{3-}$ . The remaining halide ions show this tendency to a much lesser extent.
- (14) Fluorine does not have vacant d-orbital in valence shell therefore it does not combine with F ion to form polyfluoride ions like  $Cl_3^-$ ,  $Br_3^-$ ,  $I_3^-$ ,  $I_5^-$ , etc.

### Similarities between oxygen and fluorine:

- 1. Atomic and ionic radii of both elements are very similar.
- 2. Both exist in gaseous state at room temperature.
- 3. Hydrides of both elements form associated species due to hydrogen bond formation.

$$(HF)_x$$
,  $(H_2O)_x$ 

- 4. Hydrides of both elements have abnormally high b.pts.
- 5. Hydrides of both elements are ionizing solvents.

## 12.3 FLUORINE

**Occurrence:** Fluorine is extremely reactive and hence does not occur in free state. It is widely found in the combined state as fluorides. The important minerals are:

(i) Fluorspar (Fluorite) , CaF<sub>2</sub>

(ii) Cryolite , Na<sub>3</sub>AlF<sub>6</sub>

(iii) Fluorapatite ,  $CaF_2 \cdot 3Ca_3(PO_4)_2$ 

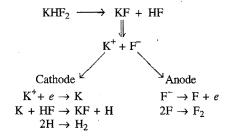

It is present in small amount as fluorides in plant-ashes, soil, sea water, bones and teeth of animals. It constitutes nearly 0.054% of earth's crust.

**Isolation:** Fluorine presented many difficulties in its isolation. It remained a difficult problem in chemistry for many years and after a hard labour of many chemists for about 75 years it could be isolated finally by **Moissan** in 1886. **The reasons for its late discovery were its high reactivity and non-conducting nature of hydrofluoric acid.** Fluorine attacked the material of the vessels used for its isolation. Carbon vessel was attacked with formation of CF<sub>4</sub> and platinum vessel was reduced to chocolate powder. The vessels of other metals were also affected. The platinum and carbon could not be used as electrodes. Another difficulty experienced was that when the electrolysis of aqueous hydrofluoric acid was carried out, hydrogen and oxygen (ozone) were obtained and when anhydrous hydrofluoric acid was tried it was found to be a bad conductor of electricity.

Moissan finally solved the problem and isolated fluorine by the electrolysis of anhydrous hydrofluoric acid in the presence of potassium hydrogen fluoride using Pt–Ir alloy vessel at -23°C. The electrodes used were also of Pt–Ir alloy.

**Modern methods of isolation:** In modern methods, fluorine is prepared by electrolysis of a fused fluoride (usually potassium hydrogen fluoride, KHF<sub>2</sub>). The electrolytic cells are made of copper, nickel or monel metal. The anode is generally of graphite and the fluorine set free contains some carbon tetrafluoride.

### Reactions in the electrolytic cell

The precautions given ahead should be taken in the preparation of fluorine:

- (i) The electrolyte must be completely dry. In presence of moisture, the evolved fluorine reacts with moisture to form  $\rm O_2$  and  $\rm O_3$ .
- (ii) The parts of the apparatus which come in contact with fluorine must be free from oil and greese.
- (iii) The vessel in which fluorine is collected should also be absolutely dry.
- (iv) The gas must be made free from HF before storing by passing through sodium fluoride (NaF) otherwise HF will attack vessel.

[Note: HF is more corrosive and reactive than fluorine.]

The electrolytic cells used are:

(a) Dennis cells and (b) Whytlaw-Gray cell

### Properties

(a) The gas is pale greenish yellow in colour. It can be condensed to yellow liquid at -188°C and pale yellow solid at -223°C. (b) It has pungent odour resembling that of a mixture of ozone and chlorine. (c) It is a poisonous gas but less poisonous than HF gas. (d) It is the most reactive element.

(i) It can displace all the halogens from their halides.

$$F_2 + 2NaX \longrightarrow 2NaF + X_2$$
  
 $(X = Cl^-, Br^- \text{ or } I^-)$   $(X_2 = Cl_2, Br_2 \text{ or } I_2)$ 

(ii) It combines with most of the metals and non-metals to form fluorides.

$$2Ag + F_2 \longrightarrow 2AgF$$

$$2Al + 3F_2 \longrightarrow 2AlF_3$$

$$Mg + F_2 \longrightarrow MgF_2$$

Hydrogen explodes violently in fluorine even in the dark.

$$H_2+F_2 \longrightarrow H_2F_2$$

A mixture of oxygen and fluorine explodes in presence of silent electric discharge.

$$O_2 + F_2 \longrightarrow O_2F_2$$
 (Dioxygen difluoride)

It reacts with wood charcoal, phosphorus, arsenic, antimony, boron, silicon producing a flame.

$$C+2F_2 \longrightarrow CF_4$$
;  $Si + 2F_2 \longrightarrow SiF_4$   
 $2P + 3F_2 \longrightarrow 2PF_3$ ;  $2As + 3F_2 \longrightarrow 2AsF_3$   
 $2B + 3F_2 \longrightarrow 2BF_3$ 

However, fluorine does not react with oxygen, nitrogen and inert gases directly under ordinary conditions.

(iii) Fluorine reacts vigorously with water giving  $O_2$  and  $O_3$ .

$$2H_2O + 2F_2 \longrightarrow 4HF + O_2$$
  
 $3H_2O + 3F_2 \longrightarrow 6HF + O_3$ 

(iv) Fluorine reacts with dilute alkalies to form oxygen difluoride (OF<sub>2</sub>) and with conc. alkalies O<sub>2</sub> is formed.

$$2F_2 + 2NaOH \longrightarrow OF_2 + 2NaF + H_2O$$
  
 $2F_2 + 4NaOH \longrightarrow 4NaF + 2H_2O + O_2$ 

(v) It acts as a strong oxidising agent. It oxidises chlorates to perchlorates, iodates to periodates and bisulphates to peroxysulphates.

$$KClO_3 + F_2 + H_2O \longrightarrow KClO_4 + H_2F_2$$
  
 $KlO_3 + F_2 + H_2O \longrightarrow KlO_4 + H_2F_2$   
 $2NaHSO_4 + F_2 \longrightarrow Na_2S_2O_8 + 2HF_2$ 

- (vi) It attacks glass at about 100°C forming SiF<sub>4</sub>. However, the attack of dry fluorine is slow. At low temperatures, dry fluorine can be stored in dry glass vessel.
- (vii) It reacts with hydrocarbons explosively and forms fluorinated hydrocarbons.

$$CH_4 \xrightarrow{F_2} CH_3F$$
  $F_2$   $CH_2F_2$   $F_2$   $CHF_3$   $F_2$   $CF_4$ 

Fluorine reacts with NH<sub>3</sub> to form nitrogen and H<sub>2</sub>S forming SF<sub>6</sub> (H<sub>2</sub>S burns).

$$2NH_3 + 3F_2 \longrightarrow N_2 + 6HF$$
  
 $H_2S + 4F_2 \longrightarrow SF_6 + 2HF$ 

- (viii) It combines with xenon to form XeF<sub>2</sub>, XeF<sub>4</sub> and XeF<sub>6</sub> (See inert gases).
  - (ix) Fluorination of methanol.

$$CH_3OH + 4F_2 \xrightarrow{AgF_2} CF_3OF + 4HF$$

CF<sub>3</sub>OF is very strong oxidising agent.

### **Uses**

- 1. It is used as an insecticide.
- 2. It is extensively used for the preparation of various fluorine compounds which have wide applications.
- (a) Freon, CCl<sub>2</sub>F<sub>2</sub> (dichloro difluoro methane), is used in refrigerators and cold storage plants.
- (b) Teflon  $(C_2F_4)_x$ , a new plastic, has a very high electrical resistance and is used as insulating material in cables. Teflon is not affected by acids, alkalies and strong oxidising agents.
- (c) H<sub>2</sub>F<sub>2</sub> is used for etching of glass and for removing silica from iron castings.

$$SiO_2 + 2H_2F_2 \longrightarrow SiF_4 + 2H_2O$$

- (d)  $UF_6$  is used in the separation of  $U^{235}$  from natural uranium by diffusion method.
- (e) SF<sub>6</sub> has insulating properties. It is used in X-ray and high voltage machines.
  - (f) Sodium fluoroacetate is used as a rat poison.
  - (g) NaF and Na<sub>3</sub>AlF<sub>6</sub> (cryolite) are used as insecticides.
- (h) CuF<sub>2</sub> is used in the ceramic industry and as a flux in soldering, welding and glazing.

### 12.4 CHLORINE

Chlorine was discovered by **Scheele** in 1774 by the action of HCl on MnO<sub>2</sub>. **Berthollet** named this gas oxymuriatic acid gas since he thought it to be an oxide of muratic acid (old name of HCl). In 1810, **Davy** established its elementary nature and named it chlorine on account of its greenish yellow colour (Greek, *chloros* = greenish yellow).

**Occurrence:** Chlorine is widely distributed in nature in the combined state in the form of chlorides of various metals. Common salt (NaCl) is the most important chloride which occurs in sea water, lakes and in rocks. The other important chloride minerals are:

- (i) Sylvite (potassium chloride), KCl
- (ii) Carnallite, KCl, MgCl<sub>2</sub>·6H<sub>2</sub>O
- (iii) Chlorapatite, 3Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>·CaCl<sub>2</sub>
- (iv) Horn silver, AgCl

**Preparation:** (i) By the oxidation of hydrochloric acid. The oxidising agents which can be used are MnO<sub>2</sub>, PbO<sub>2</sub>, Pb<sub>3</sub>O<sub>4</sub> (red lead), KMnO<sub>4</sub> (Potassium permanganate), K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> (Potassium dichromate), NaClO (Sodium hypochlorite), O<sub>3</sub>, etc.

(a) 
$$MnO_2 + 2HCl \longrightarrow MnCl_2 + H_2O + O$$
  
 $2HCl + O \longrightarrow H_2O + Cl_2$   
 $MnO_2 + 4HCl \longrightarrow MnCl_2 + 2H_2O + Cl_2$   
(b)  $PbO_2 + 4HCl \longrightarrow PbCl_2 + 2H_2O + Cl_2$   
(c)  $Pb_3O_4 + 6HCl \longrightarrow 3PbCl_2 + 3H_2O + O$ 

(d) 
$$2KMnO_4 + 6HCl \longrightarrow 2KCl + 2MnCl_2 + 3H_2O + 5[O]$$
  
 $10HCl + 5O \longrightarrow 5H_2O + 5Cl_2$ 

$$2KMn\Theta_4 + 16HCl \longrightarrow 2KCl + 2MnCl_2 + 8H_2O + 5Cl_2$$

(e) 
$$K_2Cr_2O_7 + 8HCl \longrightarrow 2KCl + 2CrCl_3 + 4H_2O + 3[O]$$
  
6HCl + 3O  $\longrightarrow 3H_2O + 3Cl_2$ 

$$K_2Cr_2O_7 + 14HCl \longrightarrow 2KCl + 2CrCl_3 + 7H_2O + 3Cl_2$$

(f) NaClO 
$$\longrightarrow$$
 NaCl + O  
2HCl + O  $\longrightarrow$  H<sub>2</sub>O + Cl<sub>2</sub>  
NaClO + 2HCl  $\longrightarrow$  NaCl + H<sub>2</sub>O + Cl<sub>2</sub>

(g) 
$$\cdot O_3 + 2HCl \xrightarrow{\sim} O_2 + H_2O + Cl_2$$

(ii) By the action of mineral acids or carbon dioxide on bleaching powder.

$$CaOCl2 + H2SO4 \longrightarrow CaSO4 + H2O + Cl2$$

$$CaOCl2 + 2HCl \longrightarrow CaCl2 + H2O + Cl2$$

$$CaOCl2 + CO2 \longrightarrow CaCO3 + Cl2$$

(iii) By heating any chloride with concentrated H<sub>2</sub>SO<sub>4</sub> in presence of MnO<sub>2</sub>.

$$MnO_2 + H_2SO_4 \longrightarrow MnSO_4 + H_2O + O$$
  
 $[NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl] \times 2$   
 $2HCl + O \longrightarrow H_2O + Cl_2$ 

 $2NaCl + MnO_2 + 3H_2SO_4 \longrightarrow 2NaHSO_4 + MnSO_4 + 2H_2O + Cl_2$ 

**Laboratory preparation:** The following methods are used in the laboratory for the preparation of chlorine:

### (i) By the Action of HCl on MnO<sub>2</sub>

The common method of preparing chlorine in the laboratory is by heating concentrated hydrochloric acid with manganese dioxide in a round-bottom flask fitted with a thistle funnel and a delivery tube (Fig. 12.3).

$$MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$$

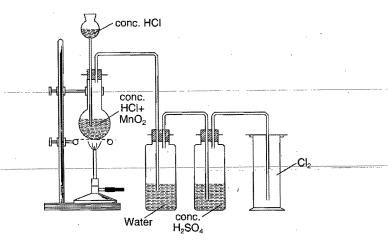

Fig 12.3

Small quantity of  $MnO_2$  is taken in the flask. Concentrated HCl is so adjusted that the end of the thistle funnel remains dipped in it. The contents are heated slowly. The yellowish green gas is evolved. The gas is usually contaminated with water vapours and HCl gas. The evolved gas is first passed through water (to remove HCl gas) and then through conc.  $H_2SO_4$  (to remove water vapours). The chlorine is finally collected in a jar by upward displacement of air.

### (ii) By the Action of HCI on KMnO<sub>4</sub>

This is a convenient method to prepare chlorine in the laboratory. It consists the addition of cold concentrated HCl on potassium permanganate crystals.

$$2KMnO_4 + 16HCl \longrightarrow 2KCl + 2MnCl_2 + 8H_2O + 3Cl_2$$
  
The apparatus used is shown in Fig. 12.4.

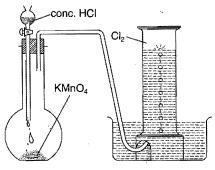

Fig. 12.4

A small quantity of potassium permanganate is placed in the flat-bottom flask fitted with a dropping funnel and a delivery tube. HCl is added drop by drop from the dropping funnel. A

brisk reaction occurs and yellowish-green gas is evolved. It is passed through water and conc. H<sub>2</sub>SO<sub>4</sub> and finally, dry and pure chlorine is collected in a jar by upward displacement.

**Pure chlorine:** It may be obtained by heating dry platinic chloride (PtCl<sub>4</sub>) or gold chloride (AuCl<sub>3</sub>) in a hard glass tube.

$$\begin{aligned} &\text{PtCl}_{4} \xrightarrow{374^{\circ}\text{C}} &\text{PtCl}_{2} + \text{Cl}_{2} \xrightarrow{582^{\circ}\text{C}} &\text{Pt} + 2\text{Cl}_{2} \\ &2\text{AuCl}_{3} \xrightarrow{175^{\circ}\text{C}} &2\text{AuCl} + 2\text{Cl}_{2} \xrightarrow{185^{\circ}\text{C}} &2\text{Au} + \beta\text{Cl}_{2} \end{aligned}$$

**Manufacture:** Bulk of chlorine required for commercial purposes is obtained as a by-product in the manufacture of caustic soda by electrolysis of brine solution or in the manufacture of sodium by electrolysis of fused sodium chloride. These processes have already been described in Chapter 6 under caustic soda and sodium.

The other methods used for its manufacture are:

- (i) Weldon's process
- (ii) Deacon's process
- (iii) Nitrosyl chloride process

These chemical methods are bit costlier and only the nitrosyl chloride process is used these days to manufacture chlorine.

### (i) Weldon's Process

This process involves the heating of pyrolusite mineral (MnO<sub>2</sub>) with concentrated hydrochloric acid in stone-ware stills.

$$MnO_2 + 4HCl \longrightarrow MnCl_2 + 2H_2O + Cl_2$$

The manganese chloride present in the waste liquor is converted into a product which can be used instead of fresh pyrolusite for oxidising more of hydrochloric acid. The manganese chloride solution is mixed with excess of lime and air is blown in the heated mixture. The following changes occur:

Calcium manganite settles down to the bottom as a dark coloured mud. This is used for oxidation of fresh quantities of hydrochloric acid.

$$CaMnO_3 + 6HCl \longrightarrow CaCl_2 + MnCl_2 + Cl_2 + 3H_2O$$

### (ii) Deacon's Process

This process is superior to Weldon's process. In this process, chlorine is obtained by the oxidation of HCl with air in presence of cupric chloride heated to 400°C.

$$4HCl + O_2 \xrightarrow{CuCl_2} 2Cl_2 + 2H_2O$$

The catalytic action of cupric chloride can be explained with the following mechanism.

$$2CuCl_2 \xrightarrow{\quad High \, temp. \quad} Cu_2Cl_2 \, + \, Cl_2$$

$$2Cu_2Cl_2 \, + \, O_2(Air) \longrightarrow 2Cu_2OCl_2 \\ \hbox{Copper oxychloride}$$

$$Cu_2OCl_2 + 2HCl \longrightarrow 2CuCl_2 + H_2O$$

The cycle is then repeated, the gaseous products being steam and chlorine.

The mixture of air and hydrochloric acid, preheated to 220°C, is introduced into a chamber containing a number of shelves on which is placed pumice stone soaked in cupric chloride solution in HCl. This chamber is surrounded by a jacket in which hot gases at 450°C are passed.

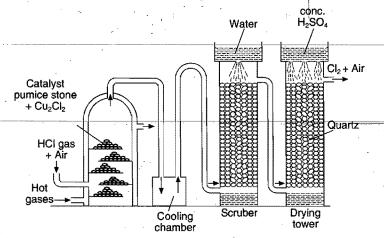

Fig. 12.5

The gaseous mixture which escapes from the top of the catalyst chamber consists Cl<sub>2</sub>, HCl, air and steam. It is freed from HCl by washing it with water in the washing tower and then dried by passing through the drying tower packed with pieces of flint and concentrated H<sub>2</sub>SO<sub>4</sub> flows down from the top. Finally, dry mixture of chlorine and air is obtained.

### (iii) Nitrosyl Chloride Process

In this process, common salt (NaCl) is treated with concentrated nitric acid, when a mixture of chlorine and nitrosyl chloride is evolved.

$$[NaCl + HNO_3 \longrightarrow NaNO_3 + HCl] \times 3$$

$$HNO_3 + 3HCl \longrightarrow NOCl + Cl_2 + 2H_2O$$

$$3NaCl + 4HNO_3 \longrightarrow 3NaNO_3 + NOCl + Cl_2 + 2H_2O$$

The gaseous mixture is oxidised with oxygen.

$$2NOC1 + O_2 \longrightarrow 2NO_2 + Cl_2$$

The gases are liquefied and chlorine distilled out. Nitrogen dioxide is absorbed in water in presence of oxygen to form nitric acid which can be used again.

$$4NO_2 + O_2 + 2H_2O \longrightarrow 4HNO_3$$

**Storage and transportation of chlorine:** Chlorine is stored and transported in the liquid state. The liquid is stored in large steel tanks which are kept in heat-insulated cold storage rooms.

### Properties of Chlorine

**Physical:** (a) Chlorine is a yellowish green gas with a pungent suffocating smell. (b) It is heavier than air and oxygen. It is 2.5 times heavier than air. (c) It is poisonous in nature. It produces headache if inhaled in small quantity. It affects throat, nose and lungs. Large quantities prove fatal.

(d) It can be easily liquefied by cooling under pressure. The liquid chlorine is a yellow liquid (b.pt. -34.6°C). (e) It is fairly soluble in water. The aqueous solution is called chlorine water. It has yellow colour and smells of chlorine. At 0°C, crystals of chlorine hydrate Cl<sub>2</sub>·8H<sub>2</sub>O are formed.

Chemical: (a) Combustibility: Chlorine does not burn and also does not help in burning.

(b) Combination with elements: It combines with all the non-metals except nitrogen, oxygen, carbon and inert gases.

It combines with hydrogen in light (but not in dark) with explosion to form HCl. However, in presence of charcoal as a catalyst, the reaction is safe.

$$H_2 + Cl_2 \longrightarrow 2HCl$$

Arsenic, boron, sulphur, phosphorus (red), etc., combine with chlorine when heated.

$$\begin{array}{c} 2As + 3Cl_2 \longrightarrow 2AsCl_3 \\ & \text{Arsenic trichloride} \\ 2B + 3Cl_2 \longrightarrow 2BCl_3 \\ & \text{Boron trichloride} \\ 2S + Cl_2 \longrightarrow S_2Cl_2 \\ & \text{Disulphur dichloride} \\ 2P + 3Cl_2 \longrightarrow 2PCl_3 \\ \text{(Red)} \qquad \begin{array}{c} Phosphorus & trichloride \\ \end{array}$$

Yellow phosphorus readily catches fire in chlorine. Most of the metals directly react with chlorine to form corresponding chlorides. Alkali metals burn brilliantly in chlorine. Iron, copper, aluminium, magnesium, zinc, etc., when heated in chlorine form corresponding chlorides. A trace of moisture always catalyse the reaction.

$$\begin{array}{c} \text{2Na} + \text{Cl}_2 \longrightarrow \text{2NaCl} & ; \text{ 2Fe} + 3\text{Cl}_2 \longrightarrow \text{2FeCl}_3 \\ \text{2Al} + 3\text{Cl}_2 \longrightarrow \text{2AlCl}_3 & ; \text{ Cu} + \text{Cl}_2 \longrightarrow \text{CuCl}_2 \\ \text{ (or Al}_2\text{Cl}_6) & & \end{array}$$

$$Mg + Cl_2 \longrightarrow MgCl_2$$
 ;  $Zn + Cl_2 \longrightarrow ZnCl_2$ 

- (c) Affinity for hydrogen: It has great affinity for hydrogen. It decomposes several hydrogen compounds forming HCl.
  - (i) Turpentine burns in chlorine forming HCl and carbon.

$$C_{10}H_{16} + 8Cl_2 \longrightarrow 10C + 16HCl$$

(ii) It reacts with water in the presence of sunlight and forms  $O_2$ .

$$2H_2O + 2Cl_2 \longrightarrow 4HCl + O_2$$

Chlorine water loses its yellow colour on exposure to sunlight. This is due to the formation of HCl.

(iii) It reacts with ammonia under two conditions:

1. When ammonia in excess: The products are nitrogen and ammonium chloride.

$$2NH_3 + 3Cl_2 \longrightarrow N_2 + 6HCl$$

$$[NH_3 + HCl \longrightarrow NH_4Cl] \times 6$$

$$8NH_3 + 3Cl_2 \longrightarrow N_2 + 6NH_4Cl$$

**2. When chlorine in excess:** The products are nitrogen trichloride and HCl.

$$NH_3 + 3Cl_2 \longrightarrow NCl_3 + 3HCl$$

(iv) It removes hydrogen from H<sub>2</sub>S.

$$H_2S + Cl_2 \longrightarrow 2HCl + S$$

(d) Oxidising and bleaching nature: In presence of moisture, chlorine acts as an oxidising and a bleaching agent. Chlorine reacts with water forming HCl and HClO (hypochlorous acid). HClO is not so stable and decomposes giving nascent oxygen which is responsible for oxidising and bleaching properties of chlorine.

$$\begin{array}{c} \text{Cl}_2 + \text{H}_2\text{O} & \longrightarrow \text{HCl} + \text{HClO} \\ & \text{HClO} & \longrightarrow \text{HCl} + \text{O} \\ \hline & \text{Cl}_2 + \text{H}_2\text{O} & \longrightarrow \text{2HCl} + \text{O} \end{array}$$

Coloured matter + Nascent oxygen - Colourless matter

The bleaching action is permanent. The delicate articles should not be bleached with chlorine.

1. It displaces bromine and iodine from bromides and iodides respectively.

$$2KBr + Cl2 \longrightarrow 2KCl + Br2 2KI + Cl2 \longrightarrow 2KCl + I2$$

2. Ferrous chloride/ferrous sulphate containing dilute H<sub>2</sub>SO<sub>4</sub>, is converted to ferric chloride/ferric sulphate.

$$2\text{FeCl}_2 + \text{Cl}_2 \longrightarrow 2\text{FeCl}_3$$
  
 $2\text{FeSO}_4 + \text{H}_2\text{SO}_4 + \text{Cl}_2 \longrightarrow \text{Fe}_2(\text{SO}_4)_3 + 2\text{HCl}$ 

3. Moist sulphur dioxide is oxidised to H<sub>2</sub>SO<sub>4</sub>.

$$SO_2 + 2H_2O + Cl_2 \longrightarrow H_2SO_4 + 2HCl_2$$

4. Sulphites are oxidised to sulphates.

$$Na_2SO_3 + H_2O + Cl_2 \longrightarrow Na_2SO_4 + 2HCl$$

5. Sulphur is precipitated from sodium thiosulphate.

$$Na_2S_2O_3 \,+\, H_2O \,+\, Cl_2 \longrightarrow \, Na_2SO_4 \,+\, 2HCl \,+\, S$$

$$Na_2S_2O_3 + 4Cl_2 + 5H_2O \longrightarrow 2NaHSO_4 + 8HCl$$

(e) Action of alkalies: When passed into cold dilute solution of alkalies, it forms chlorides and hypochlorites.

$$\begin{array}{ccc} 2NaOH + Cl_2 & \longrightarrow NaCl + NaClO + H_2O \\ 2KOH + Cl_2 & \longrightarrow KCl + KClO + H_2O \\ 2Ca(OH)_2 + 2Cl_2 & \longrightarrow CaCl_2 + Ca(ClO)_2 + 2H_2O \\ Cold \ and \ dilute \end{array}$$

With hot concentrated alkali solutions, chlorates are formed.

$$6$$
NaOH +  $3$ Cl<sub>2</sub>  $\longrightarrow$   $5$ NaCl + NaClO<sub>3</sub> +  $3$ H<sub>2</sub>  
 $6$ KOH +  $3$ Cl<sub>2</sub>  $\longrightarrow$   $5$ KCl + KClO<sub>3</sub> +  $3$ H<sub>2</sub>O  
 $6$ Ca(OH)<sub>2</sub> +  $6$ Cl<sub>2</sub>  $\longrightarrow$   $5$ CaCl<sub>2</sub> + Ca(ClO<sub>3</sub>)<sub>2</sub> +  $6$ H<sub>2</sub>O  
Hot and conc.

However, when chlorine is passed over dry slaked lime, bleaching powder is obtained.

$$\begin{array}{c} Ca(OH)_2 + Cl_2 & \longrightarrow CaOCl_2 \cdot H_2O \\ \text{Slaked lime} & \text{Bleaching powder} \end{array}$$

**(f) Addition reactions:** Chlorine forms addition compounds with SO<sub>2</sub>, CO and unsaturated hydrocarbons.

$$SO_2 + Cl_2 \xrightarrow{} SO_2Cl_2$$
;  $CO + Cl_2 \xrightarrow{} COCl_2$   
Sulphuryl chloride (Phosgene)

Phosgene is highly poisonous gas.

$$C_2H_4 + Cl_2 \longrightarrow C_2H_4Cl_2$$
Ethylene chloride

### Uses of Chlorine

It is used: (i) in the manufacture of bleaching powder, chlorates, hypochlorites, hydrochloric acid, chloroform, carbon tetrachloride and a number of synthetic organic compounds. (ii) in the purification of drinking water. (iii) as a bleaching agent for cotton fabrics, paper and rayon. (iv) in the extraction of gold and platinum. (v) as an oxidising agent. (vi) as a germicide and disinfectant. (vii) for the manufacture of poisonous gases like phosgene (COCl<sub>2</sub>), tear gas (CCl<sub>3</sub>·NO<sub>2</sub>) and mustard gas (Cl—C<sub>2</sub>H<sub>4</sub>—S—C<sub>2</sub>H<sub>4</sub>—Cl).

### 12.5 BROMINE

Bromine was discovered in 1826 by the French chemist **Balard** in the mother liquor left after the crystallisation of common salt from sea water. The name bromine was given due to its bad and pungent odour (Greek: *Bromos*, a stench).

**Occurrence:** It is never found in free state in nature. The chief sources of bromine are:

- (i) Sea water contains bromides such as NaBr, KBr, MgBr<sub>2</sub>, CaBr<sub>2</sub>, etc., in minute amounts.
- (ii) The mother liquor left after the crystallisation of potassium chloride from carnallite, KCl, MgCl<sub>2</sub>·6H<sub>2</sub>O (found in Stassfurt, Germany) contains some bromocarnallite, KBr·MgBr<sub>2</sub>·6H<sub>2</sub>O.
- (iii) The bromides such as NaBr, MgBr<sub>2</sub>, etc., are found in small amounts in mineral springs and salt lakes.
  - (iv) Bromargyrite: a mineral, AgBr.

**Preparation:** The following reactions can be used for its preparation.

(i) By passing chlorine through the solution of potassium or magnesium bromide.

$$2KBr + Cl_2 \longrightarrow 2KCl + Br_2$$
  
 $MgBr_2 + Cl_2 \longrightarrow MgCl_2 + Br_2$ 

(ii) By adding hydrochloric acid to the mixture containing potassium bromide and potassium bromate.

$$5KBr + KBrO_3 + 6HCl \longrightarrow 6KCl + 3Br_2 + 3H_2O$$

(iii) By heating mixture of potassium bromide and manganese dioxide with conc. H<sub>2</sub>SO<sub>4</sub>.

$$MnO_2 + H_2SO_4 \longrightarrow MnSO_4 + H_2O + O$$
  
 $[KBr + H_2SO_4 \longrightarrow KHSO_4 + HBr] \times 2$   
 $2HBr + O \longrightarrow H_2O + Br_2$ 

$$2KBr + MnO_2 + 3H_2SO_4 \longrightarrow 2KHSO_4 + MnSO_4 + Br_2 + 2H_2O$$

This reaction is commonly used in the laboratory for the preparation of bromine. The apparatus used has been shown in Fig. 12.6.

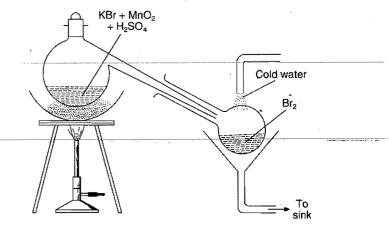

Fig. 12.6

A mixture consisting 5 g of potassium bromide and 14 g of manganese dioxide is taken in a glass retort. 30 mL concentrated sulphuric acid to which 180 mL of water has been added, is poured over the mixture in the retort. The contents are heated slowly. The reddish brown vapours of bromine are evolved. These vapours are collected in a receiver which is cooled under cold water. Bromine vapours condense to give a dark red liquid.

Since the bromine vapours are poisonous, the preparation is either carried out in a fuming cup board or in a well ventillated laboratory.

### Manufacture

1. From carnallite mother liquor: The mother liquor left after the crystallisation of potassium chloride from carnallite contains about 0.25% of bromine as magnesium bromide and potassium bromide.

The hot mother liquor is made to flow down a tower packed with earthen-ware balls (Fig. 12.7). A current of chlorine and steam is introduced from the bottom of the tower. The vapours of bromine set free are condensed in a condenser.

$$MgBr_2 + Cl_2 \longrightarrow MgCl_2 + Br_2$$

The vapours which do not condense are allowed to pass through a tower packed up with moist iron filings, forming iron bromides.

$$\begin{array}{ccc} Fe + Br_2 & \longrightarrow FeBr_2 \\ 3FeBr_2 + Br_2 & \longrightarrow Fe_3Br_8 \\ & & \text{Ferroso-ferric bromide} \end{array}$$

This is used for manufacture of potassium bromide.

The bromine so obtained contains chlorine and iodine as impurities. It is purified by distilling it with potassium bromide and zinc oxide. The bromide reacts with chlorine while zinc oxide reacts with iodine.

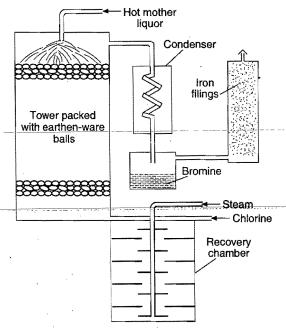

Fig. 12.7

**2. From sea water:** Sea water is the most important source of commercial bromine.

The sea water is slightly acidified and then treated with chlorine to liberate the bromine.

$$Cl_2 + Bromides \longrightarrow Chlorides + Bromine$$
(Sea water)

The evolved bromine is blown out by means of a current of air. The air carrying the bromine vapours are passed through absorption towers down which a sodium carbonate solution is sprayed. The bromide combines forming sodium bromate and sodium bromide.

$$3Na_2CO_3 + 3Br_2 \longrightarrow NaBrO_3 + 5NaBr + 3CO_2$$

The solution containing bromide and bromate is distilled with H<sub>2</sub>SO<sub>4</sub> to recover bromine.

$$[2NaBr + H_2SO_4 \longrightarrow Na_2SO_4 + 2HBr] \times 5$$
  
 $2NaBrO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + 2HBrO_3$   
 $[HBrO_3 + 5HBr \longrightarrow 3Br_2 + 3H_2O] \times 2$ 

$$10\text{NaBr} + 2\text{NaBrO}_3 + 6\text{H}_2\text{SO}_4 \longrightarrow 6\text{Na}_2\text{SO}_4 + 6\text{Br}_2 + 6\text{H}_2\text{O}$$
 or  $5\text{NaBr} + \text{NaBrO}_3 + 3\text{H}_2\text{SO}_4 \longrightarrow 3\text{Na}_2\text{SO}_4 + 3\text{Br}_2 + 3\text{H}_2\text{O}$  The vapours are condensed.

### **圏 Properties**

**Physical:** (a) It is a reddish brown, heavy mobile liquid. Its density is 3.2. It boils at 58.5°C and freezes at -7.2°C to

a yellowish brown solid. (b) It has irritating bad odour. The vapours attack the eyes and mucous membrane of nose and throat. It brings blisters on the skin which take a very long time to heal. It is poisonous. (c) It is fairly soluble in water (about 3.6% at 20°C). The solution is termed bromine water. A saturated solution of bromine when cooled in a freezing mixture gives bromine hydrate, Br<sub>2</sub>·8H<sub>2</sub>O. (d) It is more soluble in chloroform, carbon tetrachloride, benzene, carbon disulphide, etc. The colour of solution is usually reddish brown.

Chemical: In chemical behaviour, bromine closely resembles chlorine.

### (a) Combination with elements: •

(i) Bromine reacts directly with hydrogen, though less readily than chlorine. The reaction,

$$H_2 + Br_2 \longrightarrow 2HBr$$

is slightly reversible. It combines with hydrogen at 200°C or at room temperature in presence of platinum as catalyst.

(ii) It combines with sulphur, phosphorus, arsenic, etc.

$$\begin{array}{c} 2P + 3Br_2 \longrightarrow 2PBr_3 \\ 2As + 3Br_2 \longrightarrow 2AsBr_3 \\ 2B + 3Br_2 \xrightarrow{Red \, heat} 2BBr_3 \end{array}$$

(iii) It combines directly with many metals.

$$2Na + Br_2 \longrightarrow 2NaBr$$
 (Slow reaction)  
 $2K + Br_2 \longrightarrow 2KBr$  (Fast reaction)  
 $2Al + 3Br_2 \longrightarrow 2AlBr_3$  (Violent reaction)

Zinc reacts in presence of moisture with bromine.

$$Zn + Br_2 \longrightarrow ZnBr_2$$

**(b) Oxidising action:** Bromine is a good oxidising agent. It ordinarily does not react with water but in presence of an oxidisable substance it forms hydrogen bromide and oxygen with water.

$$Br_2 + H_2O \longrightarrow 2HBr + O$$
 $X + O \longrightarrow XO$ 
Oxidisable substance

(i) It oxidises SO<sub>2</sub> into sulphuric acid.

$$SO_2 + Br_2 + 2H_2O \longrightarrow 2HBr + H_2SO_4$$

(ii) It oxidises sulphites into sulphates.

$$Na_2SO_3 + Br_2 + H_2O \longrightarrow Na_2SO_4 + 2HBr$$

(iii) It oxidises arsenites into arsenates.

$$Na_3AsO_3 + Br_2 + H_2O \longrightarrow Na_3AsO_4 + 2HBr$$

(iv) It oxidises thiosulphate into sulphate.

$$Na_2S_2O_3 + Br_2 + H_2O \longrightarrow Na_2SO_4 + S + 2HBr$$

(v) Sulphur is formed by oxidation of hydrogen sulphide.

$$H_2S + Br_2 \longrightarrow 2HBr + S$$

(vi) Iodine is liberated from iodides.

$$2KI + Br_2 \longrightarrow 2KBr + I_2$$

(c) Action with alkalies: The action of bromine on alkalies is similar to that of chlorine, a hypobromite with a cold dilute solution and a bromate with a hot solution are formed.

$$\begin{array}{c} 2KOH + Br_2 \longrightarrow KBr + KBrO + H_2O \\ \text{(Dil. and cold)} & \text{Pot. hypobromite} \\ \end{array}$$

$$6KOH + 3Br_2 \longrightarrow 5KBr + KBrO_3 + 3H_2O$$
(Conc. and hot) Pot. bromate

$$6Ba(OH)_2 + 6Br_2 \longrightarrow 5BaBr_2 + Ba(BrO_3)_2 + 6H_2O$$
(Conc. and hot)

Barium

$$3Na_2CO_3 + 3Br_2 \longrightarrow 5NaBr + NaBrO_3 + 3CO_2$$
 (Conc. and hot)

However, with slaked lime (dry) it forms a compound similar to bleaching powder.

$$Ca(OH)_2 + Br_2 \longrightarrow CaOBr_2 + H_2O$$
Slaked lime
(Dry)

(d) Action of ammonia: It is similar to that of chlorine.

$$8NH_3 + 3Br_2 \longrightarrow 6NH_4Br + N_2$$

**(e) Action of organic compounds:** It forms addition compounds with unsaturated compounds and substituted products with the saturated compounds.

$$C_2H_4 + Br_2 \longrightarrow C_2H_4Br_2$$
  
 $CH_4 + Br_2 \longrightarrow CH_3Br + HBr$ 

- (f) Bleaching action: The bleaching action of bromine is weaker than that of chlorine. The bleaching action is due to its oxidising property.
- (g) Action of mercuric oxide: Bromine water reacts with mercuric oxide to form mercury oxybromide.

$$2\text{HgO} + 2\text{Br}_2 + \text{H}_2\text{O} \longrightarrow \text{HgBr}_2 \cdot \text{HgO} + 2\text{HBrO}$$

Mercury oxybromide

However, on passing bromine vapours over dry HgO at 60°C, bromine monoxide is obtained.

$$HgO + 2Br_2 \longrightarrow Br_2O + HgBr_2$$

### Uses of Bromine

- (i) The chief use of bromine is in the manufacture of ethylene bromide (C<sub>2</sub>H<sub>4</sub>Br<sub>2</sub>) which is extensively employed as a component of anti-knock gasoline.
- (ii) It is used in the manufacture of NaBr and KBr (used in medicine as sedative), and certain organic dyes.
- (iii) Bromine water is used in organic chemistry to test the unsaturation of organic compounds.
  - (iv) It is used as germicide.
- (v) It is employed as an oxidising agent and in organic synthesis.

### 12.6 IODINE

Iodine was discovered by **Courtois** in 1812 from the ashes of sea-weeds. Gay-Lussac established its elementary nature and named it iodine on account of the violet colour of its vapours (Greek; *Ioeides* = violet).

**Occurrence:** Iodine never occurs free in nature. In combined state, it occurs as iodides and sodium iodate. Traces of compounds of this element are found in plants and animals, in certain minerals and in sea water.

There are two main sources of iodine:

- (i) Certain deep sea-weeds (Laminaria species). These plants contain 0.5% of iodine in their ashes (known as kelp) in the form of iodides.
- (ii) Caliche or crude chile saltpetre which contains about 0.2% of NaIO<sub>3</sub> (sodium iodate).

The less important sources of iodine are:

- (i) Sodium, potassium and magnesium iodides in very small amounts are found in ores of lead and dolomite.
- (ii) Sea water contains iodides and organic compounds containing iodine.
  - (iii) Thyroxine which is present in thyroid gland.
  - (iv) Oil-well brines contain NaI.

**Preparation:** The following reactions can be applied for the preparation of iodine:

(i) By passing chlorine through potassium iodide solution.

$$2KI + Cl_2 \longrightarrow 2KCl + I_2$$

(ii) By adding potassium iodide solution to copper sulphate solution.

$$\begin{array}{c} \text{CuSO}_4 \,+\, 2\text{KI} \longrightarrow & \text{CuI}_2 \,+\, \text{K}_2\text{SO}_4 \\ 2\text{CuI}_2 \longrightarrow & \text{Cu}_2\text{I}_2 \,+\, \text{I}_2 \\ \text{Cupric} & \text{Cuprous} \\ \text{indide} & \text{indide} \end{array}$$

(iii) By adding conc. sulphuric acid to a mixture of sodium/potassium iodide and sodium/potassium iodate.

$$\begin{aligned} [\text{NaI} + \text{H}_2\text{SO}_4 & \longrightarrow \text{NaHSO}_4 + \text{HI}] \times 5 \\ \text{NaIO}_3 + \text{H}_2\text{SO}_4 & \longrightarrow \text{NaHSO}_4 + \text{HIO}_3 \\ \text{HIO}_3 + 5\text{HI} & \longrightarrow 3\text{H}_2\text{O} + 3\text{I}_2 \end{aligned}$$

$$\overline{\text{NaIO}_3 + 5\text{NaI} + 6\text{H}_2\text{SO}_4 \longrightarrow 6\text{NaHSO}_4 + 3\text{H}_2\text{O} + 3\text{I}_2}$$

(iv) By adding an oxidising agent such as hydrogen peroxide, ozone, acidified potassium permanganate or acidified potassium dichromate to potassium iodide.

$$2KI + H_2O_2 \longrightarrow 2KOH + I_2$$

(v) By reacting sodium iodate with sodium hydrogen sulphite.

$$2NaIO_3 + 5NaHSO_3 \longrightarrow 3NaHSO_4 + 2Na_2SO_4 + I_2 + H_2O_3$$

(vi) By heating mixture of potassium iodide and manganese dioxide with conc. H<sub>2</sub>SO<sub>4</sub>.

$$2KI + 2H_2SO_4 \longrightarrow 2KHSO_4 + 2HI$$
 $MnO_2 + H_2SO_4 \longrightarrow MnSO_4 + H_2O + O$ 
 $2HI + O \longrightarrow H_2O + I_2$ 

$$2KI + MnO_2 + 3H_2SO_4 \longrightarrow 2KHSO_4 + MnSO_4 + 2H_2O + I_2$$

Iodine, in the laboratory, is usually prepared by this reaction. The following materials are taken in a beaker, KI (3.5 g),  $MnO_2$  (7.0 g) and 6N  $H_2SO_4$  (100 mL).

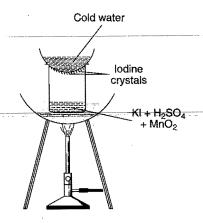

Fig. 12.8

The contents are heated and the vapours of evolved iodine are condensed on a watch glass, cooled by ice as shown in Fig. 12.8.

### Manufacture

(i) From sea-weeds: The sea-weeds are collected, dried and burnt in shallow pits. The ash left is called **kelp.** The ash is extracted with hot water which dissolves out chlorides, carbonates, sulphates and iodides of sodium and potassium.

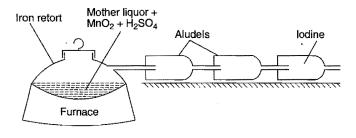

Fig. 12.9

The solution on concentration and cooling separates out chlorides, sulphates and carbonates while iodides remain in solution. The solution is mixed with manganese dioxide and concentrated sulphuric acid in iron retorts. Iodine is liberated and condensed in series of earthen-ware receivers known as *Aludels*.

$$[NaI + H2SO4 \longrightarrow NaHSO4 + HI] \times 2$$

$$MnO2 + H2SO4 \longrightarrow MnSO4 + H2O + O$$

$$2HI + O \longrightarrow H2O + I2$$

$$2 NaI + MnO_2 + 3H_2SO_4 \longrightarrow 2 NaHSO_4 + MnSO_4 + H_2O + I_2$$

Pure iodine is obtained by sublimation.

(ii) From caliche: Chile saltpetre is dissolved in water. The solution is concentrated and cooled to separate sodium nitrate crystals. The mother liquor is treated with a calculated amount of sodium hydrogen sulphite\* solution to precipitate out iodine.

$$[NaIO_3 + 3NaHSO_4 \longrightarrow NaI + 3NaHSO_4] \times 5$$

$$NaIO_3 + NaHSO_4 \longrightarrow Na_2SO_4 + HIO_3$$

$$[NaI + NaHSO_4 \longrightarrow Na_2SO_4 + HI] \times 5$$

$$HIO_3 + 5HI \longrightarrow 3H_2O + 3I_2$$

$$6$$
NaIO<sub>3</sub>+  $15$ NaHSO<sub>3</sub>  $\longrightarrow$   $9$ NaHSO<sub>4</sub>+  $6$ Na<sub>2</sub>SO<sub>4</sub>+  $3$ H<sub>2</sub>O +  $3$ I<sub>2</sub>  
or  $2$ NaIO<sub>3</sub>+  $5$ NaHSO<sub>3</sub>\*  $\longrightarrow$   $3$ NaHSO<sub>4</sub>+  $2$ Na<sub>2</sub>SO<sub>4</sub>+  $H$ <sub>2</sub>O+I<sub>2</sub>

**Purification:** Commercial iodine obtained in the above processes may contain iodine chloride (ICl), iodine bromide (IBr) and iodine cyanide (ICN) which are difficult to be removed by sublimation. The impure iodine is distilled with potassium iodide which removes the impurities and pure iodine vapours are condensed.

$$KI + ICI \longrightarrow KCl + I_2$$
  
 $KI + IBr \longrightarrow KBr + I_2$   
 $KI + ICN \longrightarrow KCN + I_2$ 

KCl, KBr and KCN are non-volatile substances.

### Properties

**Physical:** (a) It is a black (dark violet) shining solid, *i.e.*, it has metallic lustre. (b) It melts at 114°C and boils at 184°C. However, it sublimes rapidly below melting point giving violet coloured vapours. (c) Iodine produces stains on skin. Its vapours are pungent and irritating and very dangerous to inhale. (d) Its specific gravity is 4.98. It is diatomic in nature and when heated at 1700°C, it is converted into atomic form.

$$I_2 \stackrel{1700^{\circ}C}{\longleftarrow} I + I$$

(e) It is slightly soluble in water giving a light brown solution. Its solubility increases in water in presence of potassium iodide due to formation of potassium tri-iodide. KI<sub>3</sub> easily breaks down and thus the solution has all the properties of free iodine.

$$KI + I_2 \rightleftharpoons KI_3$$

(f) It is soluble in many organic solvents such as chloroform, carbon tetrachloride, alcohol, ether and carbon disulphide. The solution in CS<sub>2</sub>, CHCl<sub>3</sub> and CCl<sub>4</sub> is violet in colour.

Chemical: Iodine is chemically less reactive in comparison to chlorine and bromine.

<sup>\*</sup>NaHSO<sub>3</sub> if present in excess, HI is produced, NaHSO<sub>3</sub> + I<sub>2</sub> + H<sub>2</sub>O ---- NaHSO<sub>4</sub> + 2HI

(a) Combination with elements: It combines directly with many elements.

$$H_{2} + I_{2} \xrightarrow{\text{Heat}} 2HI$$

$$2P + 3I_{2} \xrightarrow{\text{Heat}} 2PI_{3}$$

$$2K + I_{2} \longrightarrow 2KI$$

$$2Fe + 3I_{2} \xrightarrow{\text{Heat}} 2FeI_{3}$$

**(b) Oxidising properties:** It is a weak oxidising agent. The following reactions show its oxidising nature.

(i) 
$$H_2S + I_2 \longrightarrow 2HI + S$$

(ii) 
$$SO_2 + I_2 + 2H_2O \longrightarrow H_2SO_4 + 2HI$$

(iii) 
$$Na_2SO_3 + I_2 + H_2O \longrightarrow Na_2SO_4 + 2HI$$

(iv) 
$$Na_3AsO_3 + I_2 + H_2O \longrightarrow Na_3AsO_4 + 2HI$$

(v) 
$$2\text{FeSO}_4 + \text{H}_2\text{SO}_4 + \text{I}_2 \longrightarrow \text{Fe}_2(\text{SO}_4)_3 + 2\text{HI}$$

(c) Reaction with alkalies: Iodine reacts with cold dilute solution of NaOH forming hypoiodite. The colour of the solution becomes faint yellow. However, hypoiodite undergoes hydrolysis forming HIO.

$$\begin{array}{c} \text{2NaOH} + \text{I}_2 \longrightarrow \text{NaIO} + \text{NaI} + \text{H}_2\text{O} \\ \hline \text{NaIO} + \text{H}_2\text{O} \longrightarrow \text{NaOH} + \text{HIO} \\ \hline \hline \text{NaOH} + \text{I}_2 \longrightarrow \text{NaI} + \text{HIO} \\ \hline \text{Hypoiodous acid} \\ \end{array}$$

Iodine when heated with concentrated alkali solution, iodide and iodate are formed. The colour of iodine disappears.

$$6\text{NaOH} + 3\text{I}_2 \longrightarrow \underbrace{5\text{NaI} + \text{NaIO}_3}_{\text{Colourless}} + 3\text{H}_2\text{O}$$

(d) Iodine does not displace chlorine and bromine from chlorides and bromides, respectively but it displaces them from their oxy salts.

$$2KClO_3 + I_2 \longrightarrow 2KIO_3 + Cl_2$$
  
 $2KBrO_3 + I_2 \longrightarrow 2KIO_3 + Br_2$ 

**(e) Reaction with sodium thiosulphate:** Iodine solution is decolourised by sodium thiosulphate (hypo) as sodium tetrathionate and sodium iodide are formed. Both are colourless and soluble.

$$2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$$
 Sodium thiosulphate Sodium tetrathionate

This reaction is involved in iodometric titrations in presence of starch indicator. (f) Action of NH<sub>3</sub>: Iodine forms a mild explosive with ammonia.

$$2NH_3 + 3I_2 \longrightarrow NI_3 \cdot NH_3 + 3HI$$
  
Explosive  
 $8NI_3 \cdot NH_3 \longrightarrow 5N_2 + 9I_2 + 6NH_4I$ 

- (g) Reaction with strong oxidising agents: Strong oxidising agents convert iodine to iodic acid (HIO<sub>3</sub>).
  - (i) With conc. HNO<sub>3</sub>.

$$I_2 + 10HNO_3 \longrightarrow 2HIO_3 + 10NO_2 + 4H_2O$$

(ii) With ozone.

$$I_2 + H_2O + 5O_3 \longrightarrow 2HIO_3 + 5O_2$$

(iii) With chlorine water.

$$I_2 + 5Cl_2 + 6H_2O \longrightarrow 2HIO_3 + 10HCl$$

(h) Reaction with freshly precipitated mercuric oxide: Iodine forms hypoiodous acid with mercuric oxide.

$$2HgO + 2I_2 + H_2O \longrightarrow HgI_2 \cdot HgO + 2HIO$$

(i) Iodine when warmed with alcohol and alkali forms iodoform.

$$C_2H_5OH + 6KOH + 4I_2 \longrightarrow CHI_3 + HCOOK + 5KI + 5H_2O$$

- (j) Reaction with chlorine: When chlorine is passed over iodine, at first iodine monochloride, ICl (dark liquid) and finally iodine trichloride, ICl<sub>3</sub> (yellow solid) is formed.
- (k) Reaction with starch: Iodine turns starch solution blue. This is one of the tests of iodine.
- (1) Action on unsaturated organic compounds: Addition products are formed with unsaturated organic compounds.

$$C_2H_4 + I_2 \longrightarrow C_2H_4I_2$$

#### Uses of lodine

- (a) It is used in medicine, e.g., tincture of iodine  $[\frac{1}{2}$  oz. iodine,  $\frac{1}{4}$  oz. KI and 1 pint rectified spirit] and iodex as antiseptic and analgesic. Solutions of iodine in KI are used in the treatment of goitre.
- (b) It is used in the preparation of iodoform, iodides, dyes, etc.
  - (c) It is used in the analytical chemistry.
- (d) It is used in the preparation of photosensitive papers, films and plates.

## COMPARISON OF HALOGENS (F2, Cl2, Br2 and l2)

S.No.	Property	Fluorine	Chlorine	Bromine	Iodine
1.	Physical state at	Gas ,	Gas	Liquid	Solid

## 12.7 HALOGEN ACIDS OR HYDRACIDS

All the halogens combine with hydrogen and form the covalent hydrides of HX type (X = F, Cl, Br or I). These hydrides are called hydracids or halogen acids.

Hydrogen fluoride (HF)

Hydrogen chloride (HCl)

Hydrogen bromide (HBr)

Hydrogen iodide (HI)

## Preparation (HCI, HBr and HI)

(i) By the direct combination of elements: Hydrogen chloride (HCl) is formed by burning chlorine in excess of hydrogen.

$$H_2 + Cl_2 \longrightarrow 2HCl$$

HBr can be prepared by passing a mixture of H<sub>2</sub> and Br<sub>2</sub> over a platinum spiral heated to redness by an electric current.

$$H_2 + Br_2 \xrightarrow{Pt} 2HBr$$

HI can also be prepared in small quantities by passing hydrogen and iodine vapours over red hot fine platinum.

$$H_2 + I_2 \xrightarrow{Pt} 2HI$$

(ii) By heating a halide with acid: Hydrogen chloride is prepared by heating sodium chloride with concentrated sulphuric acid.

$$2NaCl + H_2SO_4 \longrightarrow Na_2SO_4 + 2HCl$$

HBr and HI cannot be prepared by heating bromides and iodides with concentrated H<sub>2</sub>SO<sub>4</sub> because HBr and HI are strong reducing agents and reduce H<sub>2</sub>SO<sub>4</sub> to SO<sub>2</sub> and get themselves oxidised to bromine and iodine, respectively.

$$KBr + H_2SO_4 \longrightarrow KHSO_4 + HBr$$
 $KI + H_2SO_4 \longrightarrow KHSO_4 + HI$ 
 $H_2SO_4 + 2HBr \longrightarrow SO_2 + Br_2 + 2H_2O$ 
 $H_2SO_4 + 2HI \longrightarrow SO_2 + I_2 + 2H_2O$ 

Thus, HBr and HI are prepared by heating bromides and iodides respectively with conc. orthophosphoric acid.

$$3KBr + H_3PO_4 \longrightarrow K_3PO_4 + 3HBr$$
  
 $3KI + H_3PO_4 \longrightarrow K_3PO_4 + 3HI$ 

(iii) HBr and HI can be prepared by hydrolysis of corresponding phosphorus trihalides.

$$2P + 3Br_2 \longrightarrow 2PBr_3$$
  
 $2P + 3I_2 \longrightarrow 2PI_3$   
 $PBr_3 + 3H_2O \longrightarrow H_3PO_3 + 3HBr$   
 $PI_3 + 3H_2O \longrightarrow H_3PO_3 + 3HI$ 

**Hydrogen fluoride:** It is an associated molecule and is represented by formula,  $H_2F_2$ .

Pure anhydrous hydrogen fluoride is obtained by heating potassium hydrogen fluoride (dry) in a platinum retort.

$$2KHF_2 \longrightarrow K_2F_2 + H_2F_2$$

The vapours are condensed in a platinum condenser and collected in a platinum receiver. In place of platinum, lead apparatus can also be used.

The aqueous solution of  $H_2F_2$  can be obtained by heating calcium fluoride with 90% conc. sulphuric acid in a lead retort. The vapours are condensed in a strongly cooled lead receiver. Aqueous acid of about 40% strength can be obtained by passing the vapours through water in a lead receiver.

$$CaF_2 + H_2SO_4 \longrightarrow CaSO_4 + H_2F_2$$

The aqueous solution of  $H_2F_2$  is kept in qutta-percha bottles when dilute and in wax bottles when concentrated. The anhydrous acid is stored in well cooled platinum, gold or silver vessels or steel cylinders.

#### **Properties**

(i) Physical state: Except H<sub>2</sub>F<sub>2</sub>, other hydrogen halides

are gases. They fume in air and have pungent odour. These are colourless. All are heavier than air and can be liquefied to colourless liquids.

Their melting and boiling points increase with increase in atomic mass of the halogen. The low values are due to covalent nature.

	HCl .	$\mathbf{HBr}$	HI
Melting point (°C)	-111	-86	-50.8
Boiling point (°C)	-85	-67	-35.5

 $H_2F_2$  is a liquid with boiling point 19.5°C. This behaviour is due to association of HF molecules through hydrogen bonding.

(ii) Constant boiling mixtures: These are fairly soluble in water. They form constant boiling mixtures with water called azeotrope.

Hydrogen halide	Composition	Boiling point (°C
$H_2F_2$	36%	120
HCl	20.4%	110
HBr	47%	126
HI	57%	. 127

(iii) Stability: The bond strength H—X decreases from HF to HI. Thus, HF is most stable while HI is least stable. The decrease in stability is due to decrease in electronegativity from F to I. This is also observed in the values of dissociation energy of H—X bond.

	H-F	H—Cl	H—Br	H—I
Dissociation				
energy (kcal mol <sup>-1</sup> )	136	105	86	70

HF and HCl are stable upto 1200°C, HBr dissociates slightly and HI dissociates considerably (20%) at 440°C.

(iv) Acid strength: Hydrogen halides in the gaseous state are essentially covalent. In aqueous solutions, however, they ionise and act as acids. HF is only slightly ionised but HCl, HBr and HI are almost completely ionised, *i.e.*, the relative strength increases from HF to HI. HF is the weakest acid and HI is the strongest acid. On the basis of electronegativity, this appears to be rather surprising. [The electronegativity difference suggests that HF should be strongest and HI should be weakest acid.] The increase in strength is reflected from the dissociation constant values,  $K_a$ , of these hydrogen halides.

HF HCl HBr HI 
$$K_a = 7 \times 10^{-4}$$
  $7 \times 10^{8}$   $7 \times 10^{10}$   $7 \times 10^{11}$ 

The anomalous behaviour is explained with the help of **Born-Haber cycle.** The various factors which determine the strengths of the acids in aqueous medium can be represented in the form of Born-Haber cycle, as shown below:

Summation of all energy terms will be equal to  $\Delta I$ .  $\Delta I = \Delta H_1 + \Delta H_2 + \Delta H_3 - \Delta H_4 - (\Delta H_5 + \Delta H_6)$ 

The values of  $\Delta I$  for various halogen acids as calculated are given below:

$$HF$$
 HCI HBr HI  $\Delta I$  (kJ mol<sup>-1</sup>) -12 -59 -63 -57

The larger the negative value  $\Delta I$ , the greater is the feasibility of ionisation reaction and hence the greater is the strength of the halogen acid.

The value of HF is small compared to other acids, hence HF is the weakest acid. The values also explain the gradual increasing strength of HCl and HBr but fail to explain the strength of HI. This discrepency is explained on the basis of entropy changes ( $\Delta S$ ) accompanying the process of ionisation.

The lower strength of HF is largely due to its high bond dissociation energy as the bond length is very small (1.01 Å).

(v) Reducing nature: The reducing nature increases from HF to HI as the stability decreases from HF to HI. HF does not show reducing nature. It cannot be oxidised even by strong oxidising agents. HI is the strongest reducing agent. Its aqueous solution gets oxidised even by atmospheric oxygen.

$$4HI + O_2 \longrightarrow 2H_2O + 2I_2$$

The reducing action can also be explained on the basis of increasing size of the halide ions from  $F^-$  to  $I^-$ . The bigger ion can lose electron easily.

HCl can be oxidised by strong oxidising agents like MnO<sub>2</sub>, KMnO<sub>4</sub>, K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, PbO<sub>2</sub>, Pb<sub>3</sub>O<sub>4</sub>, etc. (see reactions in section 12.4).

HBr acts stronger reducing agent than HCl. It can be oxidised by  $H_2SO_4$  and atmospheric oxygen.

$$H_2SO_4 + 2HBr \longrightarrow SO_2 + Br_2 + 2H_2O$$
  
 $4HBr + O_2 \longrightarrow 2H_2O + 2Br_2$ 

HI is the strongest reducing agent.

It reduces  $H_2SO_4$  to  $SO_2$ , S and  $H_2S$ , nitric acid to  $NO_2$ , nitrous acid to NO,  $FeCl_3$  to  $FeCl_2$ , cupric salt to cuprous salt, etc.

$$H_2SO_4 + 2HI \longrightarrow SO_2 + I_2 + 2H_2O$$

$$\begin{array}{c} \text{H}_2\text{SO}_4 + 6\text{HI} \longrightarrow \text{S} + 3\text{I}_2 + 4\text{H}_2\text{O} \\ \text{H}_2\text{SO}_4 + 8\text{HI} \longrightarrow \text{H}_2\text{S} + 4\text{I}_2 + 4\text{H}_2\text{O} \\ 2\text{HNO}_3 + 2\text{HI} \longrightarrow 2\text{NO}_2 + 2\text{H}_2\text{O} + \text{I}_2 \\ 2\text{HNO}_2 + 2\text{HI} \longrightarrow 2\text{NO} + 2\text{H}_2\text{O} + \text{I}_2 \\ 2\text{FeCl}_3 + 2\text{HI} \longrightarrow 2\text{FeCl}_2 + \text{I}_2 + 2\text{HCl} \\ 2\text{CuSO}_4 + 4\text{HI} \longrightarrow \text{Cu}_2\text{I}_2 + 2\text{H}_2\text{SO}_4 + \text{I}_2 \\ \text{K}_2\text{S}_2\text{O}_8 + 2\text{HI} \longrightarrow \text{K}_2\text{SO}_4 + \text{H}_2\text{SO}_4 + \text{I}_2 \\ \text{Potassium peroxydisulphate} \end{array}$$

(vi) Precipitation reactions: HCl forms insoluble chlorides with the soluble salts of Ag, Pb and Hg(ous).

$$\begin{array}{c} \text{AgNO}_3 + \text{HCl} \longrightarrow \text{AgCl} + \text{HNO}_3 \\ \text{(White)} \\ \text{Pb(NO}_3)_2 + 2\text{HCl} \longrightarrow \text{PbCl}_2 + 2\text{HNO}_3 \\ \text{(White)} \\ \text{Hg}_2(\text{NO}_3)_2 + 2\text{HCl} \longrightarrow \text{Hg}_2\text{Cl}_2 + 2\text{HNO}_3 \\ \text{(White)} \end{array}$$

AgCl is insoluble in  $HNO_3$  but soluble in  $NH_4OH$ .  $PbCl_2$  is soluble in hot water while  $Hg_2Cl_2$  is soluble in aqua-regia.

HBr reacts with soluble salts of Ag and Pb.

$$AgNO_3 + HBr \longrightarrow AgBr + HNO_3$$
(Pale yellow)
$$Pb(NO_3)_2 + 2HBr \longrightarrow PbBr_2 + 2HNO_3$$
(White)

AgBr is insoluble in HNO<sub>3</sub> but sparingly soluble in NH<sub>4</sub>OH. PbBr<sub>2</sub> is soluble in hot water.

HI forms insoluble iodides with the salts of Ag, Pb and Hg (ic).

$$\begin{array}{c} \text{AgNO}_3 + \text{HI} & \longrightarrow \text{AgI} + \text{HNO}_3 \\ \text{(Yellow)} \end{array}$$
 
$$\text{Pb(CH}_3\text{COO)}_2 + 2\text{HI} & \longrightarrow \text{PbI}_2 + 2\text{CH}_3\text{COOH} \\ \text{(Yellow)} \end{array}$$
 
$$\text{HgCl}_2 + 2\text{HI} & \longrightarrow \text{HgI}_2 + 2\text{HCl} \\ \text{(Scarlet)} \end{array}$$

AgI is insoluble in HNO<sub>3</sub> and NH<sub>4</sub>OH. PbI<sub>2</sub> is soluble in hot water.

(vii) Action of halogens:  $F_2$  can displace  $Cl_2$ ,  $Br_2$  and  $I_2$  from HCl, HBr and HI.

$$\begin{aligned} & 2HCl + F_2 \longrightarrow 2HF + Cl_2 \\ & 2HBr + F_2 \longrightarrow 2HF + Br_2 \\ & 2HI + F_2 \longrightarrow 2HF + I_2 \end{aligned}$$

 $Cl_2$  can displace  $Br_2$  and  $I_2$  from HBr and HI and  $Br_2$  can displace only  $I_2$  from HI. Iodine can displace none.

(viii) Reaction with ammonia: HCl, HBr and HI combine with ammonia giving white fumes of ammonium halides.

Registration of the second

$$NH_3 + HCl \longrightarrow NH_4Cl$$
 (Ammonium chloride)  
 $NH_3 + HBr \longrightarrow NH_4Br$  (Ammonium bromide)  
 $NH_3 + HI \longrightarrow NH_4I$  (Ammonium iodide)

(ix) Acidic properties: All the three (HCl, HBr and HI) react with certain metals, their oxides, carbonates, hydroxides, etc., and form salts.

$$\begin{array}{c} \text{Mg} + 2\text{HX} \longrightarrow \text{Mg}\,\text{X}_2 + \text{H}_2 \\ \text{MgO} + 2\text{HX} \longrightarrow \text{Mg}\,\text{X}_2 + \text{H}_2\text{O} \\ \text{CaCO}_3 + 2\text{HX} \longrightarrow \text{CaX}_2 + \text{H}_2\text{O} + \text{CO}_2 \\ \text{NaHCO}_3 + \text{HX} \longrightarrow \text{NaX} + \text{H}_2\text{O} + \text{CO}_2 \\ \text{NaOH} + \text{HX} \longrightarrow \text{NaX} + \text{H}_2\text{O} \end{array}$$

[HX = HCl, HBr or HI]

(x) Action of salts: HCl, HBr or HI decompose the salts of weaker acids.

$$Na_{2}S + 2HX \longrightarrow 2NaX + H_{2}S$$

$$Ca_{3}P_{2} + 6HX \longrightarrow 3CaX_{2} + 2PH_{3}$$

$$Na_{2}SO_{3} + 2HX \longrightarrow 2NaX + H_{2}O + SO_{2}$$

$$2NaNO_{2} + 2HX \longrightarrow 2NaX + NO + NO_{2} + H_{2}O$$

$$Na_{2}S_{2}O_{3} + 2HX \longrightarrow 2NaX + SO_{2} + S + H_{2}O$$

## **Abnormal Properties of Hydrofluoric Acid**

Hydrofluoric acid differs from other halogen acids in the following respects:

- (i) Anhydrous hydrogen fluoride is a liquid at ordinary temperature while other halogen acids are gases. This is due to strong hydrogen bonding in hydrogen fluoride.
- (ii) It is very stable. It does not dissociate on heating while other halogen acids dissociate at definite temperatures.

It is due to decrease in the electronegativity and bond energy.

- (iii) It exists as associated molecule, H<sub>2</sub>F<sub>2</sub>, even in gaseous state. It forms two series of salts, *i.e.*, KHF<sub>2</sub>, K<sub>2</sub>F<sub>2</sub>. Other halogen acids have molecular formula, H X and form one series of salts.
  - HCl; Chlorides, e.g., NaCl, AgCl, FeCl<sub>3</sub>, BaCl<sub>2</sub>, etc.

HBr; Bromides, e.g., NaBr, AgBr, FeBr<sub>3</sub>, BaBr<sub>2</sub>, etc.

HI; Iodides, e.g., NaI, AgI, FeI3, BaI2, etc.

- (iv) It is a weak acid but is extremely stable. It is not oxidised by strong oxidising agents. On the other hand all other halogen acids are oxidised.
- (v) Hydrofluoric acid is highly poisonous and has a very high corrosive action on skin.
- (vi) Unlike other halogen acids, hydrofluoric acid attacks silica and glass. With silica, it forms silicon tetrafluoride and hydrofluosilicic acid.

$$SiO_2 + 2H_2F_2 \longrightarrow SiF_4 + 2H_2O$$
  
 $SiF_4 + H_2F_2 \longrightarrow H_2SiF_6$   
Hydrofluosilicic acid

Glass being a mixture of sodium and calcium silicates reacts with hydrofluoric acid forming sodium and calcium flurosilicates respectively.

$$Na_2SiO_3 + 3H_2F_2 \longrightarrow Na_2SiF_6 + 3H_2O$$
  
 $CaSiO_3 + 3H_2F_2 \longrightarrow CaSiF_6 + 3H_2O$ 

The etching of glass is based on these reactions.

(vii) When hydrofluoric acid is heated with a mixture of MnO<sub>2</sub> and H<sub>2</sub>SO<sub>4</sub>, no gas is evolved. On the other hand, in case of HCl, HBr and HI acids, Cl<sub>2</sub> (yellowish green), Br<sub>2</sub> (reddish brown) and I<sub>2</sub> (violet) gases are evolved.

$$MnO_2 + H_2SO_4 \longrightarrow MnSO_4 + H_2O + O$$
  
 $2HX + O \longrightarrow H_2O + X_2$ 

HX = HCl, HBr or HI

 $X_2 = \text{Cl}_2$ ,  $\text{Br}_2$  or  $\text{I}_2$ 

- (viii) With AgNO<sub>3</sub> solution, hydrofluoric acid gives no precipitate since AgF is formed which is soluble in water. On the other hand, HCl, HBr and HI give the precipitates of AgCl, AgBr and AgI respectively.
- (ix) Lead acetate does not form any precipitate with hydrofluoric acid while other halogen acids form precipitates of PbCl<sub>2</sub> (white), PbBr<sub>2</sub> (white) and PbI<sub>2</sub> (yellow) respectively.
- (x) With barium chloride solution,  $H_2F_2$  forms a white precipitate of  $BaF_2$  while other halogen acids do not form any precipitate since  $BaX_2$  (X = Br and I) are soluble.

$$H_2F_2 + BaCl_2 \longrightarrow BaF_2$$
 + 2HC

Same thing happens with the solutions of calcium chloride and strontium chloride as  $CaF_2$  and  $SrF_2$  are also insoluble.

## Uses of halogen acids

- (i) Hydrofluoric acid is used:
- (a) in the etching of glass.
- (b) in the manufacture of fluorine.
- (c) for removing silica from artificial graphite and other castings.
  - (d) as an antiseptic in brewing industries.
  - (e) for making fluorides. NaF is used as an insecticide.

AlF<sub>3</sub> is used in the extraction of aluminium. Fluorides of alkali metals and antimony are used as mordants in dyeing industry. UF<sub>6</sub> is used for separation of U<sup>235</sup> isotope by diffusion method.

#### (ii) Hydrochloric acid is used:

- (a) in the preparation of chlorine, chlorides and aqua-regia.
- (b) as a laboratory reagent.
- (c) for cleaning iron sheets during tin plating and galvanisation.
  - (d) for extraction of glue from animal tissues and bones.
  - (e) in medicines.

#### (iii) Hydrobromic acid is used:

- (a) as a laboratory reagent for preparing bromo derivatives of unsaturated organic compounds.
  - (b) for making NaBr and KBr which are used as sedatives.
  - (c) for making AgBr used in photography.

#### (iv) Hydroiodic acid is used:

- (a) as a reducing agent in organic chemistry.
- (b) for making KI which is used in medicines.
- (c) for making AgI which is used in photography.

## 12.8 OXIDES OF CHLORINE

Chlorine forms a number of oxides such as Cl<sub>2</sub>O, ClO<sub>2</sub>, Cl<sub>2</sub>O<sub>6</sub> and Cl<sub>2</sub>O<sub>7</sub>. All of them are unstable and highly reactive.

(i) Dichloro oxide, Cl<sub>2</sub>O: It is prepared by passing dry chlorine over freshly precipitated yellow mercuric oxide.

$$HgO + 2Cl_2(dry) \longrightarrow HgCl_2 + Cl_2O$$

It is a brownish yellow gas which condenses to an orange coloured liquid in a freezing mixture (b. pt. =  $2^{\circ}$ C). It has characteristic penetrating odour. Liquid Cl<sub>2</sub>O explodes readily on heating or sparking forming Cl<sub>2</sub> and O<sub>2</sub>. It also undergoes photochemical decomposition.

$$2Cl_2O \longrightarrow 2Cl_2 + O_2$$

It dissolves in water giving golden yellow solution of hypochlorous acid, HClO. It is thus anhydride of hypochlorous acid.

$$Cl_2O + H_2O \rightleftharpoons 2HClO$$

Its gaseous mixture with ammonia explodes violently.

$$3Cl_2O + 10NH_3 \longrightarrow 2N_2 + 6NH_4Cl + 3H_2O$$

It is a strong oxidising agent. It oxidises HCl to Cl<sub>2</sub>.

$$Cl_2O + 2HCl \longrightarrow 2Cl_2 + H_2O$$

 $Cl_2O$  has V-shaped structure. The oxygen atom undergoes  $sp^3$  hybridization. The Cl—O—Cl bond angle is 110.9°.

(ii) Chlorine dioxide, ClO<sub>2</sub>: Pure ClO<sub>2</sub> is obtained by passing dry Cl<sub>2</sub> over AgClO<sub>3</sub> heated to 90°C.

$$2AgClO_3 + Cl_2(dry) \longrightarrow 2AgCl + 2ClO_2 + O_2$$

It can also be obtained by the action of Cl<sub>2</sub> on sodium chlorite.

$$2NaClO_2 + Cl_2 \longrightarrow 2NaCl + 2ClO_2$$

It can be condensed by cooling to a coloured liquid (b.pt.  $11^{\circ}$ C). The gas explodes and is decomposed to  $Cl_2$  and  $O_2$  by an electric spark. It dissolves in water giving a mixture of chlorous acid and chloric acid.

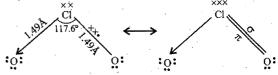

$$2ClO_2 + H_2O \longrightarrow HClO_2 + HClO_3$$

With alkalies, it gives a mixture of chlorite and chlorate.

$$2ClO_2 + 2KOH \longrightarrow KClO_2 + KClO_3 + H_2O$$

It is a powerful oxidising and bleaching agent.

It has an angular structure with O—Cl—O bond angle of 117.6°C. The molecule is supposed to contain a three electron bond. Its structure is believed to be a resonance hybrid of the following two structures:

The structure arises from  $sp^3d$  hybridization of Cl-atom. The molecule is paramagnetic due to the presence of three electron bond.

(iii) Dichlorine hexoxide,  $Cl_2O_6$ : It is obtained by mixing chlorine dioxide with ozonised air at  $0^{\circ}$ C.

$$2ClO_2 + 2O_3 \longrightarrow Cl_2O_6 + 2O_2$$

It is a dark red liquid. It is unstable and decomposed into ClO<sub>2</sub> and O<sub>2</sub>. It is a strong oxidising agent. It reacts with water forming chloric and perchloric acids.

$$Cl_2O_6 + H_2O \longrightarrow HClO_3 + HClO_4$$

It reacts with alkalies to give chlorates and perchlorates.

$$Cl_2O_6 + 2KOH \longrightarrow KClO_3 + KClO_4 + H_2O$$

With HF, it gives HClO<sub>4</sub> and chloryl fluoride.

$$Cl_2O_6 + HF \longrightarrow HClO_4 + ClO_2F$$

In the vapour state it exists as ClO<sub>3</sub> molecule which has odd number of electrons and hence paramagnetic while in liquid state it is in dimeric form having even number of electrons and hence diamagnetic in nature.

$$2ClO_3 \rightleftharpoons Cl_2O_6$$

The exact structure is unknown. However, the following structure containing Cl—Cl linkage is proposed in which each chlorine is  $sp^3$  hybridized.

The molecule is diamagnetic and has no unpaired electron. (iv) Chlorine heptoxide,  $Cl_2O_7$ : It is formed by dehydration of perchloric acid with  $P_2O_5$  at  $-10^{\circ}C$ .

$$2HClO_4 \xrightarrow{P_2O_5} Cl_2O_7 + H_2O$$

It is a colourless oily liquid which is explosive in nature. It slowly reacts with water forming perchloric acid. It is, thus, anhydride of perchloric acid.

$$Cl_2O_7 + H_2O \longrightarrow 2HClO_4$$

It is less reactive in comparison to lower oxides of chlorine.  $Cl_2O_7$  has the structure  $O_3Cl-O-ClO_3$  in which two tetrahedral are sharing one O-atom.

## 12.9 OXY-ACIDS OF CHLORINE

## 🛮 (A) Hypochlorous Acid, HClO

The acid is known only in solution. It is obtained by shaking precipitated HgO with chlorine water.

$$2$$
HgO +  $2$ Cl<sub>2</sub> +  $H_2$ O  $\longrightarrow$  Hg<sub>2</sub>OCl<sub>2</sub> +  $2$ HClO Oxychloride of mercury

Commercially, it is obtained by passing CO<sub>2</sub> through suspension of bleaching powder and then distilling.

$$2CaOCl_2 + H_2O + CO_2 \longrightarrow CaCl_2 + CaCO_3 + 2HClO$$

It is a weak acid. Its concentrated solution is yellow in colour while dilute solution is colourless. It is unstable and decomposes.

$$2HClO \longrightarrow 2HCl + O_2$$

It dissolves magnesium with evolution of hydrogen.

$$Mg + 2HClO \longrightarrow Mg(ClO)_2 + H_2$$

With alkalies, it forms salts called hypochlorites.

It acts as a powerful oxidising and bleaching agent. This is due to release of nascent oxygen easily.

$$HClO \longrightarrow HCl + O$$

CIO ion has linear shape. Linear shape results from sp<sup>3</sup> hybridization of Cl-atom.

## Bleaching powder, CaOCl<sub>2</sub>·H<sub>2</sub>O

Bleaching powder is also called calcium chlorohypochlorite because it is considered as a mixed salt of hydrochloric acid and hypochlorous acid. It is represented as:

It is manufactured by the action of chlorine on dry slaked lime, Ca(OH)<sub>2</sub>, at 40°C.

$$Ca(OH)_2 + Cl_2 \longrightarrow Ca(OCl)Cl + H_2O$$

This is the Odling view about its formation. There is another view proposed by Clifford according to which bleaching powder is a mixture of calcium hypochlorite and basic calcium chloride.

$$\begin{array}{c} 2 \text{Ca}(\text{OH})_2 + 2 \text{Cl}_2 \longrightarrow \text{Ca}(\text{OCl})_2 + \text{CaCl}_2 + 2 \text{H}_2 \text{O} \\ \hline \text{CaCl}_2 + \text{Ca}(\text{OH})_2 + \text{H}_2 \text{O} \longrightarrow \text{CaCl}_2 \cdot \text{Ca}(\text{OH})_2 \text{H}_2 \text{O} \\ \hline 2 \text{Cl}_2 + 3 \text{Ca}(\text{OH})_2 \longrightarrow \text{Ca}(\text{OCl})_2 + \text{CaCl}_2 \cdot \text{Ca}(\text{OH})_2 \text{H}_2 \text{O} + \text{H}_2 \text{O} \\ \hline \text{Bleaching powder} \end{array}$$

The manufacture of bleaching powder is carried out in any one of the following plants:

- (i) Hasenclever's plant (Old process),
- (ii) Beckmann's plant (Modern process).
- (i) Hasenclever's plant: It consists of a number of cast-iron horizontal cylinders, each provided with a rotating shaft fitted with blades and arranged as shown in Fig. 12.10.

The dry slaked lime is introduced through the hopper in the uppermost cylinder. It is pushed onwards with the help of the blades when the shaft rotates. A stream of chlorine is

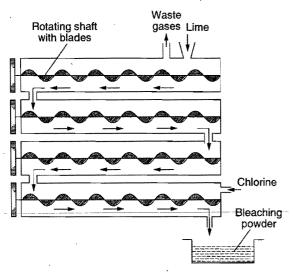

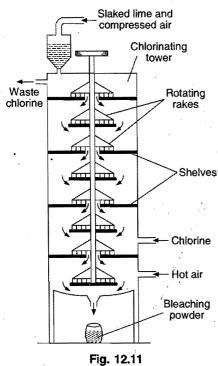

Fig. 12.10

admitted from the bottom and passes upwards. The chlorine is completely absorbed by the time till it reaches the top cylinder. Bleaching powder is collected in a barrel placed below an outlet in the lowermost cylinder while the waste gases escape from the top.

(ii) Beckmann's plant (Modern process): It consists of a vertical cast-iron tower. The tower is provided with a hopper at the top, two inlets near the base (one for chlorine and other for hot air) and an exit for waste gases near the top (Fig. 12.11).

The tower is fitted with eight shelves at different heights each equipped with rotating rakes. The slaked lime is introduced through the hopper and it comes in contact with chlorine which slowly moves upwards. Bleaching powder is collected in a barrel at the base.

The chlorine used in the manufacture of bleaching powder should be dilute and the temperature should be maintained below 40°C.

## **Properties**

- (a) It is a pale yellow powder. It has a strong smell of chlorine. It is soluble in water but a clear solution is never formed due to the presence of impurities.
- (b) On long standing, it undergoes auto-oxidation into calcium chlorate and calcium chloride.

$$6CaOCl_2 \longrightarrow Ca(ClO_3)_2 + 5CaCl_2$$

(c) In presence of cobalt chloride, CoCl<sub>2</sub>, it loses its oxygen.

$$2CaOCl_2 \xrightarrow{CoCl_2} 2CaCl_2 + O_2$$

(d) In presence of a slight amount of a dilute acid, it loses oxygen.

$$2CaOCl_2 + H_2SO_4 \longrightarrow CaCl_2 + CaSO_4 + 2HClO \longrightarrow HClO \longrightarrow HCl + O$$

On account of the formation of nascent oxygen, it shows oxidising and bleaching properties.

#### (i) Oxidising properties:

$$\begin{array}{c} \text{CaOCl}_2 + \text{H}_2\text{S} \longrightarrow \text{CaCl}_2 + \text{H}_2\text{O} + \text{S} \\ \text{CaOCl}_2 + 2\text{FeSO}_4 + \text{H}_2\text{SO}_4 \longrightarrow \text{Fe}_2(\text{SO}_4)_3 + \text{CaCl}_2 + \text{H}_2\text{O} \\ \text{CaOCl}_2 + \text{KNO}_2 \longrightarrow \text{CaCl}_2 + \text{KNO}_3 \\ 3\text{CaOCl}_2 + 2\text{NH}_3 \longrightarrow 3\text{CaCl}_2 + 3\text{H}_2\text{O} + \text{N}_2 \\ \text{CaOCl}_2 + 2\text{KI} + 2\text{HCl} \longrightarrow \text{CaCl}_2 + 2\text{KCl} + \text{H}_2\text{O} + \text{I}_2 \\ \text{Na}_3\text{AsO}_3 + \text{CaOCl}_2 \longrightarrow \text{CaCl}_2 + \text{Na}_3\text{AsO}_4 \end{array}$$

#### (ii) Bleaching action:

Coloured matter + [O] ----- Colourless product

(e) It loses its chlorine by the action of dilute acids (in excess) or carbon dioxide.

$$CaOCl2 + 2HCl \longrightarrow CaCl2 + H2O + Cl2$$

$$CaOCl2 + H2SO4 \longrightarrow CaSO4 + H2O + Cl2$$

$$CaOCl2 + CO2 \longrightarrow CaCO3 + Cl2$$

The amount of chlorine obtained from a sample of bleaching powder by treatment with excess of dilute acids or carbon dioxide is called available chlorine. A good sample of bleaching powder contains 35–38% of available chlorine.

(f) Bleaching powder converts acetone or ethyl alcohol into chloroform.

$$\begin{array}{c|c} \text{CaOCl}_2 + \text{H}_2\text{O} & \longrightarrow \text{Ca}(\text{OH})_2 + \text{Cl}_2 \\ \text{CH}_3 & & \text{CCl}_3 \\ \text{CH}_3 & & \text{CH}_3 \\ \text{CCl}_3 & & \text{CH}_3\text{COO} \\ \text{CH}_3 & & \text{CH}_3\text{COO} \\ \text{CH}_3 & & \text{Chloroform} \\ \end{array}$$

### Uses of Bleaching Powder

It is used (i) as a disinfectant and germicide especially in the sterilisation of drinking water. (ii) for manufacture of chloroform. (iii) for making wool unshrinkable. (iv) as an oxidising agent in industry. (v) mainly as bleaching agent for cotton, linen and wood pulp. However, delicate articles like straw, silk, ivory, etc., are not bleached by bleaching powder.

#### Estimation of available chlorine

The maximum percentage of available chlorine as calculated from Odling's formula comes to 49%.

The estimation of available chlorine in a given sample of bleaching powder is done volumetrically by

(i) Iodometric method or (ii) Arsenite method.

**Iodometric method:** A weighed quantity of bleaching powder is suspended in water and treated with excess of acetic acid and potassium iodide. The liberated iodine is estimated by treating with a standard solution of sodium thiosulphate using starch as an indicator.

$$\begin{array}{c} \text{CaOCl}_2 + 2\text{CH}_3\text{COOH} \longrightarrow (\text{CH}_3\text{COO})_2\text{Ca} + \text{Cl}_2 + \text{H}_2\text{O} \\ 2\text{KI} + \text{Cl}_2 \longrightarrow 2\text{KCl} + \text{I}_2 \\ 2\text{Na}_2\text{S}_2\text{O}_3 + \text{I}_2 \longrightarrow 2\text{NaI} + \text{Na}_2\text{S}_4\text{O}_6 \end{array}$$

Let V mL of  $\frac{N}{r}$  Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> be used for W g of a sample of bleaching powder.

$$V \text{ mL } \frac{N}{x} \text{Na}_2 \text{S}_2 \text{O}_3 \Longrightarrow V \text{ mL } \frac{N}{x} \text{ Iodine}$$

$$= V \text{ mL } \frac{N}{x} \text{ Chlorine}$$

$$= \frac{35.5}{x} \times \frac{V}{1000} \text{ g Chlorine}$$
Thus, % of available chlorine

$$=\frac{35.5\times V\times 100}{x\times 1000\times W}\ =\ \frac{3.55\times V}{x\times W}$$

The percentage of available chlorine in the commercial samples of bleaching powder is usually between 33-38%. The low value is due to the following factors:

- (i) Incomplete reaction between slaked lime and chlorine during its formation.
- (ii) Impurities present in the original slaked lime used for the manufacture.
  - (iii) Decomposition of bleaching powder when kept in air.

## **(B) Chlorous Acid, HCIO<sub>2</sub>**

It is obtained in aqueous solution when barium chlorite suspension in water is treated with H<sub>2</sub>SO<sub>4</sub>. The insoluble barium sulphate is filtered off.

$$Ba(ClO_2)_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HClO_2$$

The freshly prepared solution is colourless but it soon decomposes to ClO<sub>2</sub> which makes the solution yellow.

$$5HClO_2 \longrightarrow 4ClO_2 + HCl + 2H_2O$$

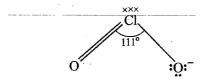

The acid undergoes auto-oxidation.

$$2HClO_2 \longrightarrow HClO + HClO_3$$

The acid liberates iodine from KI.

$$4KI + HClO_2 + 2H_2O \longrightarrow 4KOH + HCl + 2I_2$$

Chlorite ion, ClO<sub>2</sub>, has angular shape. This shape is due to sp<sup>3</sup> hybridization of Cl-atom.

## (C) Chloric Acid, HCIO<sub>3</sub>

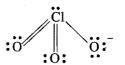

This acid is only known in solution. The acid is prepared by the action of dilute H<sub>2</sub>SO<sub>4</sub> on barium chlorate.

$$Ba(ClO_3)_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HClO_3$$

BaSO<sub>4</sub> is filtered off.

Concentrated acid is colourless and pungent smelling liquid. It decomposes in light. However, it is stable in dark. It acts as a strong oxidising and bleaching agent in light. Organic substances like paper, cotton, wool, etc., catch fire in contact with the acid.

Chlorate ion, ClO<sub>3</sub>, has pyramidal shape. The shape results due to  $sp^3$  hybridization of Cl-atom.

## (D) Potassium Chlorate, KClO<sub>3</sub>

Potassium chlorate is the salt of chloric acid, HClO<sub>3</sub>. HClO<sub>3</sub> is known only in solution but its salts are quite stable in free state under ordinary conditions.

Potassium chlorate is formed in laboratory by passing chlorine gas through hot and concentrated solution of potassium hydroxide.

$$6KOH + 3Cl_2 \longrightarrow 5KCl + KClO_3 + 3H_2O$$

When the solution is cooled, crystals of KClO<sub>3</sub> are obtained.

#### Manufacture

(i) Old process: This process involves chlorination of lime with the formation of calcium chlorate.

$$6Ca(OH)_2 + 6Cl_2 \longrightarrow Ca(ClO_3)_2 + 5CaCl_2 + 6H_2O$$

## 12.11 POLYHALIDES

Halide ions often react with molecules of halogens or interhalogen and form polyhalide ions. Iodine is only slightly soluble in water. Its solubility is greatly increased if some iodide ions are present in the solution. The increase in solubility is due to formation of a polyhalide ion,  $I_3^-$ .

$$I^- + I_2 \longrightarrow I_3^-$$

This ion is stable in aqueous solution and in ionic crystals. More complex ions such as  $I_5^-$ ,  $I_7^-$  and  $I_9^-$  have also been prepared. The  $Br_3^-$  and  $Cl_3^-$  ions are much less stable than  $I_3^-$ .

Many polyhalides are known which contain two or three different halogens, for example K[ICl<sub>2</sub>], K[ICl<sub>4</sub>], Cs[IBrF] and K[IBrCl]. These are formed from interhalogens and metal halides.

$$ICl + KCl \longrightarrow K[ICl_2]$$

$$ICl_3 + KCl \longrightarrow K[ICl_4]$$

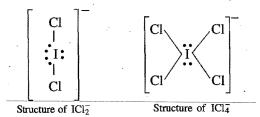

$$ICl + KBr \longrightarrow K[IBrCl]$$

Polyhalides are typical ionic compounds (crystalline, stable and soluble in water, conduct electricity when in solution) though they tend to decompose on heating. The products of decomposition are governed by the lattice energy of the products. The lattice energy of the alkali metal halides is higher for the smaller halide ions, so the smaller halogen remain bonded to the metal.

$$\begin{array}{ccc} Rb[ICl_2] & \xrightarrow{Heat} & RbCl + ICl \\ K[BrICl] & \xrightarrow{Heat} & KCl + IBr \\ Cs[I_3] & \longrightarrow & CsI + I_2 \end{array}$$

All polyhalides are coloured. The bromo iodides are red and chlorobromides are yellow, *i.e.*, the depth of the colour increases

with increase of atomic number of the halogen atoms present. Trihalide anions like  $ICl_2$ ,  $I_3$ , [IBrCl] have symmetrical linear shape. This shape results from  $sp^3d$  hybridization of central atom. Similarly the structures of the pentahalide ions  $[ICl_4]$  and  $[BrF_4]$  are square planar. This shape results from  $sp^3d^2$  hybridization of central atom.

## 12.12 BASIC PROPERTIES OF IODINE

In general, metallic or basic properties in halogens increase on moving down the group. Iodine shows maximum basic properties in halogen family elements although it is not a metal. The compounds in which iodine functions as cationic constituent are numerous and well established. Some examples are given below:

Compounds containing unipositive iodine (I<sup>+</sup>)

ICl, IBr, INO<sub>3</sub>,  $[I(py)_2]NO_3$ ,  $[I(py)_2]ClO_4$ ,  $I_2SO_4$ 

Compounds containing tripositive iodine (I<sup>3+</sup>)

 $I(ClO_4)_3,\ I(CH_3COO)_3,\ IPO_4,\ I(NO_3)_3,\ ICl_3$ 

# 12.13 PSEUDOHALIDES AND PSEUDOHALOGENS

A few ions are known, consisting of two or more electronegative atoms of which at least one is nitrogen, that have properties similar to those of halide ions. These ions are called pseudohalide ions. Pseudohalide ions are univalent and these form salts resembling halide salts. For example, sodium salts are soluble in water but the silver salts are insoluble. The hydrogen compounds are acids like the halogen acids, HX. The pseudohalide ions are:

Cyanide ion (CN) ; Isocyanide ion (NC)

Cyanate ion (OCN) ; Fulminate ion (ONC)

Thiocyanate ion (SCN) ; Isothiocyanate ion (NCS)

Selenocyanate ion (SeCN) ; Tellurocyanate ion (TeCN)

Azide ion (N3) ; Azido carbon disulphide ion (SCSN3)

The salts formed by above ions are called pseudohalides. As the dimers of halide ions are called halogens, the covalent dimers of the pseudohalide ions are called pseudohalogens or halogenoids. So far only few of pseudohalogens have been isolated and characterised. The pseudohalogens known are:

Cyanogen (CN)<sub>2</sub> ; Oxycyanogen (OCN)<sub>2</sub> Thiocyanogen (SCN)<sub>2</sub> ; Selenocyanogen (SeCN)<sub>2</sub> Tellurocyanogen (TeCN)<sub>2</sub> ; Azido carbon disulphide (SCSN<sub>3</sub>)<sub>2</sub>

The best known pseudohalide is CN. This resembles Cl, Br and I in the following respects:

- (i) It forms an acid, HCN.
- (ii) It can be oxidised to (CN)<sub>2</sub> molecule.
- (iii) It forms insoluble salts with Ag<sup>+</sup>, Pb<sup>2+</sup> and Hg<sup>2+</sup>.
- (iv) It forms large number of complexes similar to halide complexes, e.g.,

 $\left[Cu(CN)_4\right]^{2-}$  and  $\left[CuCl_4\right]^{2-}$ ,  $\left[Co(CN)_6\right]^{3-}$  and  $\left[CoCl_6\right]^{3-}$ 

- (v) Inter-pseudohalogen compounds ClCN, BrCN and ICN can be formed.
- (vi) AgCN is insoluble in water but soluble in ammonia like AgCl.

(vii) HCN is oxidised like HCl.

$$MnO_2 + 4HCN \longrightarrow Mn(CN)_2 + (CN)_2 + 2H_2O$$
  
 $MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$ 

# SOME SOLVED PROBLEMS

**Example 1.** Which of the halogens (F, Cl, Br or I) provides an example of?

- (a) the weakest acid, HX,
- (b) the largest atom,
- (c) the smallest ionisation potential,
- (d) the strongest oxidising agent,
- (e) the highest electron affinity,
- (f) the highest electronegativity,
- (g) liquid state under ordinary conditions.

#### **Solution:**

- (a) The weakest acid is HF. Thus, fluorine forms the weakest acid.
  - (b) The largest atom is of iodine.

- (c) The smallest ionisation potential is of iodine.
- (d) The strongest oxidising agent is fluorine.
- (e) The highest electron affinity is of chlorine.
- (f) Fluorine has the highest electronegativity.
- (g) Bromine is in liquid state under ordinary conditions.

**Example 2.** Arrange the halogen hydrides in the increasing order of:

(i) dipole moment, (ii) reducing power, (iii) thermal stability, (iv) bond length, (v) ionic character.

#### **Solution:**

- (i) HI < HBr < HCl < HF (Increasing dipole moment)
- (ii) HF < HCl < HBr < HI (Increasing reducing nature)
- (iii) HI < HBr < HCl < HF (Increasing thermal stability)

- (iv) HF < HCl < HBr < HI (Increasing bond length)
- (v) HI < HBr < HCl < HF (Increasing ionic character)

**Example 3.** Give relevant chemical equations for the preparation of:

- (i) Chlorine from sodium chloride.
- (ii) Iodine from Kelp.
- (iii) Hydrobromic acid from potassium bromide.
- (iv) Bleaching powder from slaked lime.
- (v) KClO<sub>3</sub> from sodium chloride.

#### **Solution:**

(i) Chlorine is obtained from sodium chloride by carrying the electrolysis of its aqueous solution.

NaCl 
$$\rightleftharpoons$$
 Na<sup>+</sup> + Cl

H<sub>2</sub>O  $\rightleftharpoons$  H<sup>+</sup> + OH

At Cathode: H<sup>+</sup> + e<sup>-</sup>  $\longrightarrow$  H

2H  $\longrightarrow$  H<sub>2</sub>↑

At Anode: Cl<sup>-</sup>  $\rightleftharpoons$  Cl+ e<sup>-</sup>

2Cl  $\longrightarrow$  Cl<sub>2</sub>↑

(ii) The ash of sea-weeds (Kelp) is extracted with water, the sulphates and chlorides of Na and K present in it are removed by crystallisation. The mother liquor is now heated with  $MnO_2$  and conc.  $H_2SO_4$ . The iodine vapours are collected in earthen jars.

$$2\text{NaI} + 3\text{H}_2\text{SO}_4 + \text{MnO}_2 \longrightarrow 2\text{NaHSO}_4 + \text{MnSO}_4 + 2\text{H}_2\text{O} + \text{I}_2$$

(iii) HBr is prepared by heating KBr with conc. phosphoric acid.

$$3KBr + H_3PO_4 \longrightarrow K_3PO_4 + 3HBr$$

(iv) Slaked lime is treated with chlorine gas by slowly moving forward dry slaked lime in a series of shelves provided with rotating rakes.

$$Ca(OH)_2 + Cl_2 \longrightarrow CaOCl_2 \cdot H_2O$$

(v) Sodium chlorate is first obtained by carrying electrolysis of hot concentrated solution of sodium chloride in an electrolytic cell.

NaCl 
$$\xrightarrow{\text{Electrolysis}}$$
  $H_2 + Cl_2$  Solution  $Cathode$  Anode

$$Na^+ + OH^- \longrightarrow NaOH$$

Cl<sub>2</sub> reacts with NaOH forming NaClO<sub>3</sub>.

$$6$$
NaOH +  $3$ Cl<sub>2</sub>  $\longrightarrow$   $5$ NaCl + NaClO<sub>3</sub> +  $3$ H<sub>2</sub>O

KCl is added to form sparingly soluble KClO<sub>3</sub>.

$$NaClO_3 + KCl \longrightarrow KClO_3 + NaCl$$

Example 4. A liquid A is treated with Na<sub>2</sub>CO<sub>3</sub> solution. A mixture of two salts B and C are produced in the solution. The mixture on acidification with sulphuric acid and distillation produces the liquid A again. Identify A, B and C and write the equations involved.

[LLT. 1997]

#### **Solution:**

The liquid A is bromine which on treatment with sodium carbonate forms a mixture of NaBr and NaBrO<sub>3</sub> (sodium

bromate). The mixture with conc.  $H_2SO_4$  on distillation gives the liquid bromine again.

$$3Br_2 + 3Na_2CO_3 \longrightarrow 5NaBr + NaBrO_3 + 3CO_2$$
  
 $5NaBr + NaBrO_3 + 3H_2SO_4 \longrightarrow 3Na_2SO_4 + 3Br_2 + 3H_2O_3$ 

**Example 5.** Gradual addition of KI solution to  $Bi(NO_3)_3$  solution initially produces a dark brown precipitate which dissolves in excess of KI to give a clear yellow solution. Write chemical equations for the above reactions. [I.I.T. 1996]

#### Solution:

Bi(NO<sub>3</sub>)<sub>3</sub> undergoes hydrolysis. Nitric acid is formed. HNO<sub>3</sub> oxidises KI, *i.e.*, I<sub>2</sub> (brown ppt.) is formed. The precipitated iodine dissolves in excess of KI and forms a yellow coloured solution of KI<sub>3</sub>.

$$\begin{array}{c} \text{Bi(NO}_3)_3 \, + \, \text{H}_2\text{O} \longrightarrow \text{Bi(OH)(NO}_3)_2 \, + \, \text{HNO}_3 \\ \\ 6\text{KI} \, + \, 8\text{HNO}_3 \longrightarrow \, 6\text{KNO}_3 \, + \, 2\text{NO} \, + \, 3\text{I}_2 \, + \, 4\text{H}_2\text{O} \\ \\ \text{Brown ppt.} \\ \\ \text{KI} \, + \, \text{I}_2 \longrightarrow \, \text{KI}_3 \\ \\ \text{Yellow soln.} \end{array}$$

**Example 6.** An inorganic compound (X) gives a brick red flame on performing flame test. This compound gives the following tests also.

- (a) Smells of chlorine when placed in moist air.
- (b) If KI and CH<sub>3</sub>COOH are added to the suspension in water, a brown colour is obtained.

Identify (X) and write down equations for reactions at steps (a) and (b).

#### **Solution:**

Compound (X) gives a brick red flame in flame test. Thus, it is a calcium compound. It smells of chlorine on exposure suggests that it is bleaching powder. It is confirmed by reaction (b).

(a) 
$$6\text{CaOCl}_2 \longrightarrow 5\text{CaCl}_2 + \text{Ca}(\text{ClO}_3)_2$$
  
 $\text{CaOCl}_2 + \text{CO}_2 \longrightarrow \text{CaCO}_3 + \text{Cl}_2$   
(b)  $\text{CaOCl}_2 + 2\text{CH}_3\text{COOH} \longrightarrow (\text{CH}_3\text{COO})_2\text{Ca} + \text{H}_2\text{O} + \text{Cl}_2$   
 $2\text{KI} + \text{Cl}_2 \longrightarrow 2\text{KCl} + \text{I}_2$ 

**Example 7.** Explain the following:

- (i) In the preparation of HI from KI, phosphoric acid is preferred to sulphuric acid.
  - (ii) Boiling point of HCl is lower than HF. [M.L.N.R. 1992]
- (iii) F—F bond in fluorine is weaker than Cl—Cl bond in chlorine. [M.L.N.R. 1993]
- (iv) Fluorine exhibits only oxidation state -1 while other halogens exhibit negative as well as positive oxidation states.
- (v) Bleaching powder loses its bleaching property when kept in an open bottle for a long time.

#### **Solution:**

(i) Besides acidic nature of sulphuric acid, it acts as an oxidising agent. H<sub>2</sub>SO<sub>4</sub> oxidises HI (reducing agent) formed from KI into iodine. Thus, H<sub>3</sub>PO<sub>4</sub> is preferred as it does not oxidise HI.

$$2KI + 2H_2SO_4 \longrightarrow 2KHSO_4 + 2HI$$
  
 $H_2SO_4 + 2HI \longrightarrow I_2 + SO_2 + 2H_2O$ 

- (ii) In HF, there is hydrogen bonding. It is, therefore, an associated liquid. No hydrogen bonding is present in HCl. Only van der Waals' forces are present. This is the reason why boiling point of HCl is lower than HF.
- (iii) The dissociation energy of F—F bond is lower than Cl—Cl bond.

The low dissociation energy of fluorine is due to high interelectronic repulsions between non-bonding electrons in the 2porbitals as the size of fluorine atom is small. As a result F—F bond is weaker than Cl—Cl bond.

- (iv) Fluorine is the most electronegative element. It shows only -1 oxidation state as it saturates its valency shell. It cannot show any positive oxidation state as d-orbitals are not present in valency shell while d-orbitals are present in rest of the halogens.
- (v) Bleaching action of bleaching powder is due to release of Cl<sub>2</sub> at the time of application. Chlorine is lost by bleaching powder on long standing in open by the following two processes.

(a) 
$$CaOCl_2 + CO_2(air) \longrightarrow CaCO_3 + Cl_2$$

(b) 
$$6\text{CaOCl}_2 \longrightarrow 5\text{CaCl}_2 + \text{Ca(ClO}_3)_2$$

Thus, CaCl<sub>2</sub> and Ca(ClO<sub>3</sub>)<sub>2</sub> do not release Cl<sub>2</sub> at the time of use. Hence, bleaching property is lost by bleaching powder on exposure for long time.

**Example 8.** Fluorine does not form oxy-acids but other halogens do, why?

#### **Solution:**

In oxy-acids, the central element always exhibits positive oxidation states. Fluorine, being the most electronegative, never shows positive oxidation states, hence F does not form oxy-acids.

Other halogens have the tendency to show positive oxidation states and hence form oxy-acids.

**Example 9.** (a) Explain why ClF<sub>3</sub> exists whereas FCl<sub>3</sub> does not?

(b) Both NO and ClO<sub>2</sub> are odd electron species. NO dimerises but ClO<sub>2</sub> does not. Why?

#### Solution:

(a)  $CIF_3$  is known because chlorine can exhibit +3 oxidation state due to promotion of 3p-electron to 3d vacant orbital.

3s 3p	3d	
$\uparrow\downarrow$ $\uparrow\downarrow\uparrow\downarrow$ $\uparrow$		Ground state chlorine atom
$\uparrow \downarrow \qquad \uparrow \qquad \uparrow$	<u> </u>	Excited state
sp <sup>3</sup> d-hybridization	on	

Each of the three singly occupied orbitals overlap with *p*-orbital of each of the three fluorine atoms to form ClF<sub>3</sub> (trigonal bipyramidal geometry, T-shaped molecule).

No d-orbitals are present in the valency shell of fluorine and thus excitation is not possible. Fluorine, therefore, does not exhibit positive oxidation state and so the formation of FCl<sub>3</sub> is not possible.

(b) In NO, the size of nitrogen atom is small and the odd electron is attracted by only one oxygen atom while in ClO<sub>2</sub>, the size of chlorine atom is comparatively large and odd electron is attracted by two oxygen atoms. As a result, the odd electron on N in NO is localised while the odd electron on chlorine in ClO<sub>2</sub> is delocalised. Thus, NO has a tendency to dimerise but-ClO<sub>2</sub> does not.

**Example 10.** Assign appropriate reasons for each of the following statements.

- (a) More metal fluorides are ionic in nature than metal chlorides.
- (b) Addition of  $Cl_2$  to KI solution gives it a brown colour but excess of  $Cl_2$  turns it colourless.
  - (c) Perchloric acid is a stronger acid than sulphuric acid.
- (d) Fluorine does not undergo disproportionation reactions but other halogens do.

#### **Solution:**

- (a) A bigger anion is more easily polarized than a smaller anion by the same metal cation according to Fajan's rules. F ion is smaller in size in comparison to Cl ion. Thus, the metal fluoride is more ionic than the metal chloride for the same metal cation.
- (b) Chlorine being more stronger oxidising agent than I<sub>2</sub>, displaces iodine from KI which brings brown colour to the solution. In excess of Cl<sub>2</sub>, the liberated iodine is further oxidised to iodic acid and solution becomes colourless.

$$Cl_2 + 2KI \longrightarrow 2KCl + I_2$$
(Brown)
$$I_2 + 5Cl_2 + 6H_2O \longrightarrow 2HIO_3 + 10HCl$$
(Colourless)

- (c) The oxidation state of chlorine in  $HClO_4$  is +7 while that of S in  $H_2SO_4$  is +6. Thus O—H group in  $HClO_4$  is easily broken than in  $H_2SO_4$ . Hence,  $HClO_4$  is a stronger acid in comparison to  $H_2SO_4$ .
- (d) F being the most electronegative element shows only -1 oxidation state while other halogens show both negative (-1) and positive (+1, +3, +5, +7) oxidation states. Thus, fluorine does not show disproportionation reactions.

# 0

# **SUMMARY AND IMPORTANT POINTS TO REMEMBER**

- 1. 17th or VIIA group of the periodic table consists of fluorine, chlorine, bromine, iodine and astatine. These elements are collectively called as **halogens** as their salts are found in sea water (Halogen is a Greek word meaning sea salt).
- 2. Halogens are p-block elements as the last differentiating electron is accommodated on np subshell. These elements have seven electrons in their outermost shell, i.e., they have  $ns^2np^5$  configuration.

ns			np		
 $\uparrow\downarrow$	-	$\uparrow\downarrow$	_↑↓	1	_

They are all paramagnetic atoms.

- 3. These are highly reactive elements and never found free in nature but always in combined state. The salts of chlorine, bromine and iodine are found in sea water. The most common compounds of chlorine found on earth surface are common salt or table salt or rock salt (NaCl), sylvine (KCl), horn salt (AgCl), carnallite (MgCl<sub>2</sub>·KCl·6H<sub>2</sub>O), etc. Ashes of certain deep sea-weeds (Laminaria species) contain 0.5% of iodine as iodides. Chile saltpetre (caliche) contains NaIO<sub>3</sub> in minute quantity (0.2%). Bromine is usually obtained from sea water. The last member, astatine, is radioactive in nature.
- **4.** All halogens exist as diatomic molecules  $(X_2)$ . At room temperature,  $Cl_2$  and  $F_2$  are gases,  $Br_2$  is a fuming liquid while  $I_2$  is a volatile solid. The intermolecular forces are weak van der Waals' forces, whose magnitude increases from  $F_2$  to  $I_2$ . The melting/boiling points of halogens increase down the group.
- 5. Atomic radii are smallest within their respective periods. The atomic radii increase from F to I in moving down the group. They readily form  $X^-$  ions and the ionic radii also increase from  $F^-$  to  $I^-$ .
- 6. These elements have high ionisation energies. The values decrease in moving down the group. Iodine forms positive ions, i.e., it shows metallic nature. In the group, non-metallic decreases from F to I.
- 7. All the halogens are coloured.

The colour of the halogens is due to absorption of some wavelengths of visible light by their molecules to cause the promotion of electrons to higher energy molecular orbitals.

8. (a) The halogens have high electronegativity values. The values decrease from F to I.

- (b) The values of atomic volume and density increase steadily from F to I.
- (c) Halogens have high values of electron affinities.

The low value of electron affinity of fluorine is probably due to small size of fluorine atom, *i.e.*, electron density is high which hinders the addition of an extra electron.

Bond length (X—X) increases from F to I.
 Bond energy of F<sub>2</sub> molecule is, however, low inspite of shorter bond length.

Lower value of bond dissociation energy of fluorine is due to high interelectronic repulsions between non-bonding electrons in 2p-orbitals of fluorine.

- 10. (a) All halogens show a common oxidation state of -1 since each halogen having seven electrons in the valency shell tries to accept one more electron to attain 8 electrons when combines with less electronegative element.
  - (b) Fluorine being most electronegative, always shows −1 oxidation state only.
  - (c) Chlorine, bromine and iodine show positive oxidation states +1, +3, +5 and +7, +3, +5 and +7 oxidation states due to the promotion of valency electrons to *d*-orbitals which are vacant.
  - (d) Besides +3, +5 and +7 oxidation states, +4 and +6 oxidation states are also shown by these elements in oxides and oxyacids.
- 11. Standard reduction potentials of halogens are positive and decrease from F to I. Thus, halogens act as strong oxidising agents and their oxidising power decreases from F to I. In general, a halogen of low atomic number will oxidise the halide ion of higher atomic number.
- 12. F ion does not show any reducing nature but Cl, B and I ion act as reducing agents and their reducing nature is in increasing order.
- 13. Nearly, all metals combine with fluorine either in cold or on heating to form fluorides. Chlorine combines with a large number of metals but slowly. Bromine and iodine do not react with noble metals and even with less active metals. The reactivity of halogens towards metals decreases on moving down the group. The halides are predominantly ionic in nature. For a particular metal the ionic character decreases from F to I. With metals in higher oxidation states, the halides are covalent in nature.

Halogens also combine with a number of non-metals. The reactivity decreases from F to I.

- 14. Fluorine decomposes water very readily even in dark at low temperature, forming a mixture of O<sub>2</sub> and O<sub>3</sub>. Chlorine decomposes water in presence of sunlight while bromine decomposes water slowly in presence of sunlight. Iodine does not decompose water.
- 15. All the halogens react with hydrogen to form volatile covalent hydrides of the formula HX. The activity of halogens

toward hydrogen decreases from F to I. These hydrides are called hydracids or halogen acids.

- (a) The hydracids are formed by direct combination of halogens and hydrogen.
  - The aqueous solution of HF can be obtained by heating CaF<sub>2</sub> with conc. H<sub>2</sub>SO<sub>4</sub> in a lead retord. Hydrogen chloride can be prepared by NaCl with conc. H<sub>2</sub>SO<sub>4</sub>. However, HBr and HI cannot be prepared by heating bromides and iodides with conc. H<sub>2</sub>SO<sub>4</sub> because HBr and HI are strong reducing agents and oxidised by conc. H<sub>2</sub>SO<sub>4</sub> into Br<sub>2</sub> and I<sub>2</sub> respectively. HBr and HI are obtained by heating bromides and iodides with H<sub>3</sub>PO<sub>4</sub> or hydrolysis of corresponding phosphorus trihalides.
- (b) Except HF or H<sub>2</sub>F<sub>2</sub>, other halides are gases. They fume in air and have pungent odour. All are heavier than air. H<sub>2</sub>F<sub>2</sub> is a liquid due to association of molecules through hydrogen bonding. The boiling points vary as:

(c) The bond strength decreases from HF to HI. The decrease in stability is due to decrease in electronegativity. The dissociation energy of H—X bond decreases.

$$\frac{H - F}{136 \text{ kcal mol}^{-1}} > H - Cl > H - Br > H - I$$

- (d) The reducing nature increases from HF to HI. HF does not show reducing nature.
- (e) Dipole moment of these hydrides decreases from HF to HI.
- (f) Acidic nature of these hydrides is HI > HBr > HCl > HF.

  This is because of the fact that the strength of the conjugate base increases as:

$$I^- < Br^- < Cl^- < F^-$$

- (g) HCl, HBr and HI form one series of salts while hydrofluoric acid forms two series of salts MHF<sub>2</sub> and M<sub>2</sub>F<sub>2</sub> (M is monovalent).
- 16. Halogens and oxygen do not combine directly with each other. However, these compounds have been obtained indirectly. The known compounds are:

$$\begin{array}{cccc} OF_2 & Cl_2O & Br_2O & I_2O_5 \\ O_2F_2 & ClO_2 & BrO_2 & \\ & Cl_2O_6 & BrO_3 & \\ & Cl_2O_7 & \end{array}$$

The compounds of oxygen and fluorine are not called oxides but fluorides as fluorine is more electronegative than oxygen.

- (a) Oxides of Cl, Br and I are acidic and acidic character increases with increase of percentage of oxygen in them.
- (b) All the oxides of halogens are powerful oxidants, highly reactive and unstable towards heat. In general, higher oxides are relatively more stable than lower oxides for a particular halogen.
  - (c) Oxygen fluorides do not form oxyacids.
  - (d) In these oxides, bonds are mainly covalent due to small difference in the electronegativity of oxygen and halogens.

- (e) All the three monoxides, viz., OF<sub>2</sub>, Cl<sub>2</sub>O and Br<sub>2</sub>O have tetrahedral structure involving sp<sup>3</sup> hybridization of oxygen, bond angle increases with increase in size of the halogen atom.
- (f) Oxides of iodine I<sub>2</sub>O<sub>4</sub> and I<sub>4</sub>O<sub>9</sub> are not true oxides but iodates, IO(IO<sub>3</sub>) and I(IO<sub>3</sub>)<sub>3</sub> respectively.
- 17. Except fluorine, all other halogens form oxyacids of the type HXO, HXO<sub>2</sub>, HXO<sub>3</sub> and HXO<sub>4</sub>. Some of these acids are quite unstable.

- (a) All these acids are monobasic and the halogen atom is  $sp^3$  hybridized.
- (b) Acidic character increases with increase in oxidation number of the halogen.

(c) In any series, acidic character decreases as the electronegativity decreases.

$$HClO_4 > HBrO_4 > HIO_4$$

(d) Oxidising nature for the same halogen decreases.

(e) Stability for the same halogen increases.

$$HCIO' < HCIO_2 < HCIO_3 < HCIO_4$$

**18.** Fluorine reacts with cold dilute alkalies yielding OF<sub>2</sub> and with conc. alkalies evolve oxygen.

$$2F_2 + 2NaOH \longrightarrow 2NaF + OF_2 + H_2O$$
;  
 $Cold + dil$ .  
 $2F_2 + 4NaOH \longrightarrow 4NaF + O_2 + 2H_2O$   
 $Conc$ .

Cl<sub>2</sub>, Br<sub>2</sub> and I<sub>2</sub> behave similarly towards alkalies. With dilute and cold alkalies form a mixture of halide and hypohalide while with hot and conc. alkalies form a mixture of halide and halate.

$$\begin{array}{c} {\rm 2NaOH} + X_2 \longrightarrow {\rm Na}X + {\rm Na}X{\rm O} + {\rm H_2O}; \\ {\rm Cold+dil.} & {\rm Hypohalite} \\ {\rm 6NaOH} + 3X_2 \longrightarrow {\rm 5Na}X + {\rm Na}X{\rm O_3} + {\rm 3H_2O} \\ {\rm Hot+conc.} & {\rm Halate} \end{array}$$

19. The halogens on account of difference in the electronegativities combine with each other to form compounds of the type  $AB_n$  where A is always bigger atom and B is smaller, atom and n may have values 1, 3, 5 and 7. These are covalent compounds and called interhalogen compounds.

AB type CIF, BrF, BrCl, ICl, IBr  

$$AB_3$$
 type CIF<sub>3</sub>, BrF<sub>3</sub>, ICl<sub>3</sub>  $\longrightarrow sp^3d$  hybridization of A.  
Two lone pairs  
 $AB_5$  type IF<sub>5</sub>, BrF<sub>5</sub>  $\longrightarrow sp^3d^2$  hybridization of A.  
One lone pair  
 $AB_7$  type IF<sub>7</sub>  $\longrightarrow sp^3d^3$  hybridization of A.

Interhalogen compounds are gases or liquids. These are volatile and fume in air. These compounds are more reactive

than halogens except fluorine because A—B bond is weaker than B—B bond. These are hydrolysed and act as oxidising agents.

20. Halide ions often react with molecules of halogens or interhalogens and form polyhalides.

$$I^- + I_2 \longrightarrow I_3^-$$

 $I_3^-$  (polyhalide) ion is stable in aqueous solution and in ionic crystals. More complex ions such as  $I_5^-$ ,  $I_7^-$  and  $I_9^-$  have been prepared. The  $Br_3^-$  and  $Cl_3^-$  ions are much less stable than  $I_3^-$ .

Many polyhalides are known in which two or three different halogens are present such as ICl<sub>2</sub>, ICl<sub>4</sub>, (IBrF) and (IBrCl).

21. Some of the monovalent ions made of electronegative atoms and possessing properties similar to halide ions are known which are called pseudohalide ions. The corresponding dimers having no charge of these pseudohalide ions are called pseudohalogens.

Pseudohalide ions
Cyanide ion (CN<sup>-</sup>)
Thiocyanate ion (SCN<sup>-</sup>)
Cyanate ion (OCN<sup>-</sup>)

Cyanate ion (OCN<sup>-</sup>)

Pseudohaliogens
(CN)<sub>2</sub> Cyanogen
(SCN)<sub>2</sub> Thiocyanogen
(OCN)<sub>2</sub> Oxycyanogen

- 22. The important minerals of fluorine are:
  - (i) Fluorspar (CaF<sub>2</sub>); (ii) Cryolite (Na<sub>3</sub>AlF<sub>6</sub>); (iii) Fluorapatite [CaF<sub>2</sub>·3Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>]

In small amounts, it is present as fluorides in plant ashes, soil, sea water, bones and teeth of animals.

The isolation presented many difficulties. It was finally isolated by **Moissan** in 1886 by electrolysis of anhydrous hydrofluoric acid in potassium hydrogen fluoride (KHF<sub>2</sub>) using Pt–Ir vessel at –23°C. The electrodes used were also of Pt–Ir alloy.

In modern methods, fluorine is prepared by electrolysis of fused KHF<sub>2</sub>. The electrolytic cells are made of copper, nickel or monel metal. The anode is generally of graphite. The fluorine set free contains some carbon tetrafluoride. The methods used are: (i) Dennis and (ii) Whytlaw-Gray.

- 23. The fluorine compounds have wide applications:
  - (a) Freon, CF<sub>2</sub>Cl<sub>2</sub> (dichlorodifluoro methane) is used in refrigerators and cold storage plants.
  - (b) Teflon (C<sub>2</sub>F<sub>4</sub>)<sub>x</sub>, a new plastic, has a very high electrical resistance and is used as insulating material. It is not affected by acids, alkalies and strong oxidising agents.
  - (c)  $H_2F_2$  is used for etching of glass.
  - (d) SF<sub>6</sub> has insulating properties. It is used in X-ray and high voltage machines.
  - (e) NaF and Na<sub>3</sub>AlF<sub>6</sub> are used as insecticides.
  - (f) CuF<sub>2</sub> is used in ceramic industry.
  - (g) UF<sub>6</sub> is used for separation of U<sup>235</sup> isotope from natural uranium.
  - (h) Sodium fluoroacetate is used as a rat poison.
- 24. Chlorine was discovered by Scheele in 1774. The old name is oxymuriatic acid gas. Common salt (NaCl) is the most important chloride which occurs in sea water, lakes and in rocks. It is prepared (i) by oxidation of HCl with MnO<sub>2</sub>, PbO<sub>2</sub>,

Pb<sub>3</sub>O<sub>4</sub>, KMnO<sub>4</sub>, K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, O<sub>3</sub>, NaClO, etc. (ii) by heating dry platinum chloride (PtCl<sub>4</sub>) or gold chloride (AuCl<sub>3</sub>) in a hard glass tube. It gives pure chlorine.

The methods used for its manufacture are:

- (a) Weldon's process  $(MnO_2 + HCl)$  (b) Deacon's process-chlorine is obtained by air oxidation of HCl in presence of  $CuCl_2$  as a catalyst (c) Nitrosyl chloride process (d) By-product in the manufacture of caustic soda or sodium. Chlorine is stored and transported in liquid state.
- 25. Chlorine is a yellowish green gas with pungent suffocating and poisonous nature. It is fairly soluble in water. The aqueous solution is called chlorine water which gives crystals of chlorine hydrate (Cl<sub>2</sub>·8H<sub>2</sub>O) at 0°C. In presence of moisture, it acts as an oxidising and bleaching agent.
- 26. Chlorine is used in the manufacture of bleaching powder, chlorates, hypochlorites, HCl, chloroform, CCl<sub>4</sub>, phosgene (COCl<sub>2</sub>), tear gas (CCl<sub>3</sub>·NO<sub>2</sub>) and mustard gas (Cl—C<sub>2</sub>H<sub>4</sub>—S—C<sub>2</sub>H<sub>4</sub>—Cl). It is used in purification of drinking water and as a bleaching agent for cotton fabrics, paper and rayon.
- 27. Bromine was discovered by **Balard** in 1826. It is obtained either from the mother liquor obtained after crystallising KCl from carnallite or from sea water by passing Cl<sub>2</sub> gas. The vapours are absorbed in Na<sub>2</sub>CO<sub>3</sub> solution when a mixture of NaBr and NaBrO<sub>3</sub> is obtained which is distilled with H<sub>2</sub>SO<sub>4</sub> to recover bromine.
- **28.** Iodine was discovered by **Courtois** in 1812. Two main sources of iodine are:
  - (a) Deep sea-weeds' ashes known as kelp contains 0.5% iodine in the form of iodides.
  - (b) Caliche or crude chile saltpetre which contains 0.2% of NaIO<sub>3</sub>.
- **29.** I<sub>2</sub> is slightly soluble in water. The solubility can be increased by addition of KI.

$$KI + I_2 \longrightarrow KI_3$$
 (Soluble)

It is soluble in organic solvents such as chloroform, carbon tetrachloride, alcohol, ether, etc. It oxidises  $Na_2S_2O_3$  into sodium tetrathionate. This reaction is useful in iodometric titrations.

30. Tincture of iodine is a mixture of I<sub>2</sub> and KI dissolved in rectified alcohol. It is used as antiseptic. Iodex—a product containing iodine is used as antiseptic and analgesic. Although iodine does not displace chlorine or bromine from the solutions of their salts, yet it displaces them from their oxysalts.

$$2KClO_3 + I_2 \longrightarrow 2KIO_3 + Cl_2$$
  
 $2KBrO_3 + I_2 \longrightarrow 2KIO_3 + Br_2$ 

31. Bleaching powder (CaOCl<sub>2</sub>·H<sub>2</sub>O) is also called calcium chlorohypochlorite because it is a mixed salt of hydrochloric acid and hypochlorous acid. It is represented as:

It is obtained by the action of Cl2 on slaked lime.

Bleaching powder loses its chlorine content by the action of dilute acids or carbon dioxide. The amount of chlorine obtained from the sample of a bleaching powder by this way is termed **available chlorine**. A good sample of bleaching powder contains 35–38% of available chlorine.

On long standing bleaching powder undergoes autooxidation into calcium chlorate and calcium chloride.

$$6CaOCl_2 \longrightarrow 5CaCl_2 + Ca(ClO_3)_2$$

The products do not have available chlorine. Thus, bleaching powder loses available chlorine with time.

- 32. When a chloride is heated with conc. H<sub>2</sub>SO<sub>4</sub> in presence of solid K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in a dry test tube, deep red vapours of chromyl chloride are evolved. When these vapours are passed through NaOH solution, the solution becomes yellow due to formation of sodium chromate. The solution is neutralised with acetic acid and on addition of lead acetate solution, a yellow precipitate of lead chromate is formed. This is a test of chloride ion and is known as chromyl chloride test.
- 33. Warming KClO<sub>3</sub> with conc. HCl gives a mixture of Cl<sub>2</sub> and ClO<sub>2</sub> known as euchlorine which is a bleaching agent.

- 34. Iodine shows electropositive nature as it has lowest ionisation potential among halogens. It has the tendency to lose electron or electrons to form I<sup>+</sup> and I<sup>3+</sup> cations. Compounds such as ICl, ICN, ICl<sub>3</sub>, IPO<sub>4</sub>, I(CH<sub>3</sub>COO)<sub>3</sub>, etc., are known.
- 35. Some of the products of halogens have been given special names.

$Mg(ClO_4)_2$		Anhydrone
KClO <sub>3</sub>		Berthelot's salt
KHF <sub>2</sub>	-	Ferming's salt
Aq. soln. of NaOCl		Javelle water
CaOCl <sub>2</sub> ·H <sub>2</sub> O	_	Bleaching powder
Cl <sub>2</sub> and ClO <sub>2</sub> mixture	-	Euchlorine
Soln. of HCl		Spirit of salt
CCl <sub>3</sub> ·NO <sub>2</sub>	_	Tear gas
$\mathbf{C}_{\mathbf{b}}$		Oxymuriatic acid gas

36. Cl<sub>2</sub> and F<sub>2</sub> do not react with starch solution. Br<sub>2</sub> gives yellow colour with starch solution and I<sub>2</sub> gives deep blue colour with starch solution.

# ••- PRACTICE PROBLEMS

## Subjective Type Questions

- 1. Name the element of group 17, which has the following properties:
  - (a) highest electron affinity
  - (b) strongest oxidising agent
  - (c) radioactive
  - (d) violet solid
  - (e) does not exhibit positive oxidation state
- 2. Among the hydrides of halogens predict the hydride having:
  - (a) highest boiling point
  - (b) strongest reducing agent
  - (c) most stable
  - (d) least acidic
  - (e) lowest boiling point
- 3. Complete and balance the following chemical reactions:
  - (i)  $I_2 + NaClO_3 \longrightarrow$
  - (ii)  $IO_3^- + I^- + H^+ \longrightarrow$
  - (iii)  $Br_2 + NaI \longrightarrow$
  - (iv)  $I_2 + S_2O_3^{2-} \longrightarrow$
  - (v)  $BrO_3^- + F_2 + OH^- \longrightarrow$
- 4. Answer the following:
  - (i) Write the general electronic configuration of halogens in the valence shell.
  - (ii) Name the halogens.
  - (iii) Name the radioactive (last) element of VIIA or 17th group.
  - (iv) Write the physical states of halogens under ordinary conditions.

- (v) Write the two important minerals of fluorine.
- (vi) Name four oxyacids of chlorine. Give their molecular formulae.
- (vii) Name the halogen which gives ozone with water.
- (viii) Name the oxide of chlorine which has odd number of electrons and paramagnetic in nature.
- (ix) Give one example each of the compound of chlorine in which it shows +1, -1, +3, +4, +5, +6 and +7 oxidation state.
- (x) Name the halogen which has highest bond energy amongst halogens.
- (xi) Name the compound which on electrolysis gives fluorine gas at anode.
- (xii) Name the fluoro carbon used in refrigerators.
- (xiii) Name two poisonous gases of chlorine used in the warfare.
- (xiv) What is the atomicity of halogens?
- (xv) What is the percentage of available chlorine in a good sample of bleaching powder?
- (xvi) Name two interhalogens of AB<sub>3</sub> type.
- (xvii) What are the constituents of tincture of iodine?
- (xviii) What is the colour of vapours obtained when an iodide is heated with conc. H<sub>2</sub>SO<sub>4</sub>?
- (xix) What is the shape of HClO<sub>4</sub>?
- (xx) What is the shape of ClF<sub>3</sub>?
- 5. Complete the following reactions and give balanced equations:
  - (i)  $Cl_2 + OH^- \longrightarrow \dots + ClO_3^- + \dots$
  - (ii)  $MnO_2 + HCl \longrightarrow MnCl_2 + \dots + \dots$

- - (xi)  $H_2SO_4 + HI \longrightarrow \dots + \dots + \dots$ [Roorkee 1998]

(xii)  $CaOCl_2+NaI+HCl \longrightarrow .....+CaCl_2+H_2O+NaCl$ [Roorkee 1998]

- 6. What happens when? (Give balanced equations)
  - (i) Sodium iodate is treated with sodium bisulphite solution.
  - (ii) Chlorine is passed through hot NaOH solution.
    [M.L.N.R. 1990]
  - (iii) Chlorine is passed into aqueous potassium hydroxide.
  - (iv) Chlorine gas is bubbled through a solution of ferrous bromide.
  - (v) Iodine reacts with conc. HNO<sub>3</sub>. [M.L.N.R 1992]
  - (vi) Chlorine is passed over slaked lime.
  - (vii) Sodium chloride is heated with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and conc. H<sub>2</sub>SO<sub>4</sub>. [I.I.T. 1990]
  - (viii) Potassium iodide is heated with MnO<sub>2</sub> and conc. H<sub>2</sub>SO<sub>4</sub>.
  - (ix) Chlorine reacts with Na<sub>2</sub>SO<sub>3</sub> solution.
  - (x) Iodine is added to stannous chloride solution.
  - (xi) Chlorine is passed through a suspension of iodine.
  - (xii) Cl<sub>2</sub> is passed through a suspension of CaCO<sub>3</sub>.
  - (xiii) Chlorine gas is passed through dry and aqueous sulphur dioxide.
  - (xiv) Bromine reacts with Na<sub>2</sub>CO<sub>3</sub> solution.
  - (xv) Potassium iodide is added to bleaching powder containing dilute acetic acid.

#### 7. Arrange the following:

- (a) HClO<sub>2</sub>, HClO<sub>3</sub>, HClO<sub>4</sub> in increasing order of thermal stability.
- (b) HClO<sub>2</sub>, HClO<sub>3</sub>, HClO<sub>4</sub> in order of increasing acid strength.
- (c) HClO<sub>2</sub>, HClO<sub>3</sub>, HClO<sub>4</sub> in order of increasing oxidising power.
- (d) F, Cl, Br, I in order of increasing reducing nature.
- (e) I<sub>2</sub>, HI, HIO<sub>4</sub>, ICl in order of increasing oxidation number of iodine.
- (f) HOF, HOCl, HOBr, HOI in order of increasing acid strength.
- (g) F<sub>2</sub>, Cl<sub>2</sub>, Br<sub>2</sub>, I<sub>2</sub> in order of increasing oxidising power.
- (h) HF, HCl, HBr, HI in order of increasing acid strength.

- (i) F, Cl, Br, I in order of increasing electronegativity or reactivity.
- (j) F, Cl, Br, I in order of increasing electron affinity.
- **8.** Write chemical formula and uses of the following:
  - (i) Muriatic acid (ii) Freon (iii) Hypo solution
  - (iv) Caliche (v) Kelp (vi) Bleaching powder.
- 9. Give equations only:
  - (i) How chlorine is obtained from the following substances?
     (a) HCl
     (b) NaCl
     (c) KClO<sub>3</sub>
     (d) Bleaching powder
  - (ii) How bromine is obtained from the following substances? (a) NaBrO<sub>3</sub> (b) HBr (c) KBr
  - (iii) How iodine is obtained from the following substances?
    (a) KI (b) NaIO<sub>3</sub> (c) HI
- 10. What is the oxidation number of the various halogen atoms present in the following?
  - (i) CIF (ii) ICl (iii) PCl<sub>5</sub> (iv) Cl<sub>2</sub> (v) KClO<sub>3</sub> (vi) KClO<sub>4</sub> (vii) HClO<sub>2</sub> (viii) Cl<sub>2</sub>O (ix) F<sub>2</sub>O (x) Cl<sub>2</sub>O<sub>7</sub>.
- 11. What is the geometry and hybridization of the central atom of the following molecules or ions?
  - (i)  $ClO_2^-$  (ii)  $ClO_3^-$  (iii)  $IF_7$  (iv)  $ICl_2^-$  (v)  $ICl_4^-$  (vi)  $Cl_2O$  (vii)  $IF_3$  (viii)  $ClO_2$ .
- 12. Write short notes on:
  - (i) Available chlorine.
  - (ii) Interhalogen compounds.
  - (iii) Pseudohalogens.
  - (iv) Basic properties of iodine.
  - (v) Use of bleaching powder in textile industry.
  - (vi) Relative acid strength of the hydracids of halogens.
  - (vii) Relative oxidising nature of halogens.
  - (viii) Relative acid strength of the oxyacids of chlorine.
- 13. (i) Describe the iodometric method for estimating available chlorine in the given sample of bleaching powder.
  - (ii) Give the chemistry of the test of fluoride.
  - (iii) Give the chemistry of chromyl chloride test.
  - (iv) Give the chemistry of chloroform test for the detection of bromide and iodide ions.
- 14. Explain the following with proper reason:
  - (i) Fluorine cannot be prepared from fluorides by chemi cal oxidation.

[Hint: The standard reduction potential of fluorine is maximum.

$$: F \cdot + e^{-} \longrightarrow : F : -$$

Thus, it cannot be oxidised by any other reagent. F<sup>-</sup> ion is very stable due to small size and high electronegativity of fluorine atom.]

(ii) Anhydrous HCl is a bad conductor of electricity while aqueous HCl is a good conductor. [I.I.T. 1995]
 [Hint: In anhydrous state, HCl is a covalent molecule. In aqueous solution, HCl combines with water molecule to form H<sub>3</sub>O<sup>+</sup> and Cl<sup>-</sup> ions.

$$HCl + H_2O \longrightarrow H_3O^+ + Cl^-$$

(iii) Halogens are coloured.

[Hint: Halogens absorb part of the light in the visible region which cause excitation of outer electrons to higher energy levels. The excitation energy depends on the size of the halogen atom, the smaller the atom, the greater is the excitation energy. Thus, fluorine absorbs violet light and thus appears yellow (complementary colour). As different colours are absorbed by halogens, they display different complementary colours also.]

(iv) Halogens are strong oxidising agents.

[Hint: Halogens act as strong oxidising agents because they have high tendency to accept electron, *i.e.*, they have high electron affinity values. Their reduction potentials are high (positive) and decrease from F to I. Thus, oxidising nature decreases from F to I.]

(v) When a blue litmus is dipped into a solution of hypochlorous acid, it first turns red and then later gets decolourised.

[Hint: HClO is an acid, thus turns blue litmus into red. HClO is also an oxidising agent. The nascent oxygen given by HClO bleaches the red litmus.

Red litmus + 
$$O \longrightarrow Colourless$$
]

(vi) The bleaching action of chlorine is permanent while that of sulphur dioxide is temporary.

[Hint: Chlorine bleaching action is due to oxidation while that of sulphur dioxide is due to reduction. Hence, the substance bleached by SO<sub>2</sub> is reoxidised by the oxygen of the air to its original state.]

(vii) The brown colour of an acidified dilute solution of iodine in aqueous potassium iodide is intensified by addition of a nitrite but is discharged by the addition of sulphite.

[Hint: Nitrite ions oxidise iodide ions to iodine and thus brown colour is intensified.

$$4H^+ + 2NO_2^- + 2I^- \longrightarrow 2NO + I_2 + 2H_2O$$
  
Iodine acts as an oxidising agent with sulphite and converted into  $I^-$ , *i.e.*, the solution becomes colourless.

$$I_2 + SO_3^{2-} + H_2O \longrightarrow SO_4^{2-} + 2H^+ + 2\Gamma$$

(viii) Fluorine is a non-metal whereas iodine shows some metallic properties as well.

[Hint: Ionisation potential decreases on moving down from F to I. The iodine can lose electron/electrons and form positive ions and hence shows metallic character.]

(ix) Colour of potassium iodide solution containing starch turns blue when chlorine water is added.

[Hint: Chlorine being more reactive displaces iodine from KI. Iodine is absorbed by starch and thus blue colour is developed.

$$2KI + Cl_2 \longrightarrow 2KCl + I_2$$
  
 $I_2 + Starch \longrightarrow Blue colour$ 

(x) Pure HI kept in a bottle acquires a brown colour after sometime. [Hint: HI is a strong reducing agent. It is even oxidised by oxygen of the air. The iodine is liberated which is dissolved imparting a brown colour to solution.]

(xi) Iodine dissolves more in KI solution than in water.

#### [Dhanbad 1992]

[Hint: I<sub>2</sub> is a covalent molecule. Thus, its solubility is less in polar solvent, *i.e.*, water. Potassium iodide combines with iodine and forms a polyhalide which is an ionic compound. Being ionic, KI<sub>3</sub> is more soluble.

$$KI + I_2 \longrightarrow KI_3(K^+I_3)$$

(xii) Iodine is liberated in the reaction between KI and Cu<sup>2+</sup> but chlorine is not liberated when KCl is added to Cu<sup>2+</sup> ion.

[Hint: I ion is a strong reducing agent. It reduces Cu<sup>2+</sup> ion to Cu<sup>+</sup> ion. The Cl ion is a weak reducing agent. Thus, it does not reduce Cu<sup>2+</sup> ion.

$$2Cu^{2+} + 4KI \longrightarrow Cu_2I_2 + I_2 + 4K^+$$

(xiii) KHF<sub>2</sub> is well known whereas KHCl<sub>2</sub> or KHBr<sub>2</sub> does not exist.

[Hint: Hydrofluoric acid exists as dimeric molecule (H<sub>2</sub>F<sub>2</sub>) due to hydrogen bonding. It, thus, exhibits dibasic nature and forms two series of salts, KHF<sub>2</sub> as [K<sup>+</sup> and F<sup>-</sup> - - - H—F] and KF[K<sup>+</sup> and F<sup>-</sup>]. HCl and HBr exist as monomeric molecules as hydrogen bonding is not present.]

(xiv) A fresh iodine stain can be removed by washing with hypo solution.

[Hint: Hypo reacts with iodine to form water soluble colourless sodium tetrathionate and sodium iodide.

$$2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$$

(xv) Dry chlorine does not bleach clothes.

[Hint: The bleaching action of chlorine is due to the liberation of nascent oxygen from water (moisture).

$$H_2O + Cl_2 \longrightarrow 2HCl + (O)$$

(xvi) Ferric iodide is very unstable but ferric chloride is stable.

[Him: I<sup>-</sup> ion is a strong reducing agent. Iodide thus reduces ferric into ferrous. Cl<sup>-</sup> ion is a weak reducing agent and does not reduce Fe<sup>3+</sup> to Fe<sup>2+</sup>.]

(xvii) HF is least volatile and HCl is most volatile amongst hydrogen halides.

[Hint: In covalent compounds, the boiling point increases with increase of molecular mass as van der Waals' forces increase. The volatility thus, decreases in covalent compounds with increase in molecular mass. However, hydrogen bonding is present in HF. Due to which, the boiling point of HF is higher and the volatility is less. Thus, the volatility of hydrogen halides can be represented as:

(xviii) Fluorine does not form  $F_3^-$  (polyhalide) ion.

[Hint: No d-orbitals are present in fluorine while d-orbitals are present in other halogens. The formation of  $X_3^-$  ion involves  $sp^3d$  hybridization.]

(xix) Fluorine gives fumes with moist air.

[Hint: Fluorine reacts with water to form HF.

$$2H_2O + 2F_2 \longrightarrow 4HF + O_2$$

HF, being liquid, absorbs liquid droplets to form

(xx) Interhalogens are more reactive than halogens.

[Hint: The bond in the interhalogen A - X is weaker than X—X bond in the halogens. This is on account of less effective overlapping between orbitals of dissimilar atoms than those of similar atoms.]

(xxi) HF is not stored in glass bottles but kept in wax

[Hint: HF attacks glass bottles. The sodium and pota--ssium-silicates-are-converted-into-fluorosilicates.

$$Na_2SiO_3 + 6HF \longrightarrow Na_2SiF_6 + 3H_2O$$

(xxii) HF has a greater electronegativity difference and more ionic character than HCl, HBr and HI but it is the weakest acid.

Hint: The weakest acidic nature of HF is due to following three factors:

- (i) Strong H-F bond as the dissociation energy
- (ii) Large heat of dehydration due to hydrogen bonding.
- (iii) Low value of electron affinity.]
- 15. The following statements are correct under certain conditions. Mention the conditions.
  - (i) Chlorine is a good bleaching agent.
  - (ii) A mixture of H<sub>2</sub> and Cl<sub>2</sub> explodes.
  - (iii) Cl2 reacts with NaOH solution to produce sodium chloride and sodium hypochlorite (along with water).
  - (iv) Cl2 reacts with NaOH solution to produce sodium chloride and sodium chlorate (along with water).
  - (v) Cl<sub>2</sub> substitutes hydrogen atoms of a molecule of methane.
  - (vi) Cl<sub>2</sub> reacts with ammonia to form nitrogen and ammonium chloride.
  - (vii) Cl<sub>2</sub> reacts with lime to form bleaching powder.
  - (viii) Iodine dissolves freely in water.
  - (ix) Chlorine forms an addition product with SO<sub>2</sub>.
- 16. A black powder when heated with NaCl and conc. H<sub>2</sub>SO<sub>4</sub> gives off a greenish yellow gas. The gas on passing through liquor ammonia liberates N2 and on passing through boiling KOH yields compounds one of which when heated with the black powder evolves oxygen. Name the gas and the black

- powder. Explain the chemical reactions involved with
- 17. A sodium salt is heated with concentrated sulphuric acid. The evolved gas is found to turn moist litmus paper red and produce white fumes in contact with a glass rod moistened with ammonia solution. It also gives white precipitate when passed through AgNO3 solution. When the salt is heated with MnO<sub>2</sub> and conc. H<sub>2</sub>SO<sub>4</sub>, a gas with an irritating smell is evolved which turns starch-iodide paper blue. Identify the salt and the gaseous product evolved from it. Explain your answer with relevant chemical equations.
- 18. A certain compound (X) shows the following reactions.
  - (i) When KI is added to an aqueous suspension of (X)containing acetic acid, iodine is liberated.
  - (ii) When CO<sub>2</sub> is passed through an aqueous suspension of (X), the turbidity transforms to a precipitate.
  - (iii) When the paste of (X) in water is heated with ethyl alcohol, a product of anaesthetic use is obtained. Identify (X) and write down chemical equations for reactions at step (i), (ii) and (iii). [Roorkee 1992]
- 19. A colourless inorganic compound imparts a green colour to flame. It's solution does not give any precipitate with H2S. It's solution gives white precipitate with H<sub>2</sub>SO<sub>4</sub>. When it is heated with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and conc. H<sub>2</sub>SO<sub>4</sub>, a red gas is evolved. The gas when passed through aqueous NaOH solution turns it yellow. Identify the compound and give chemical reactions.

## Matching Type Questions

#### Match the following:

[A]

(i) Fluorine

(a) Carnallite

(ii) Chlorine

(b) Hydrogen bonding

(iii) Bromine

(c) Beckmann's process

(iv) Iodine

(d) Reducing agent

(v) Bleaching powder

(e) Pseudohalogen

(vi) HF

(f) Dennis process

(vii) HI

(g) Sea-weeds

(viii) (CN)2

(h) Deacon's process

B

(i) Moissan

(a) Chlorine

(ii) Scheele

(b) Bleaching powder

(iii) Balard

(c) Iodine

(iv) Courtois

(d) Fluorine

(v) Odling

(e) Bromine

## tuswers

**Answers:** Subjective Type Questions

- 1. (a) Cl (b) F (c) At (d) I (e) F
- (a) HF (b) HI (c) HF (d) HF (e) HCl
- 3. (i)  $I_2 + 2NaClO_3 \longrightarrow 2NaIO_3 + Cl_2$ 
  - (ii)  $IO_3^- + 5I^- + 6H^+ \longrightarrow 3I_2 + 3H_2O$
  - (iii)  $Br_2 + 2NaI \longrightarrow 2NaBr + I_2$
  - (iv)  $I_2 + 2S_2O_3^{2-} \longrightarrow S_4O_6^{2-} + 2I^{-}$
  - (v)  $BrO_3^- + F_2 + 2OH^- \longrightarrow BrO_4^- + 2F^- + H_2O$
- **4.** (i)  $ns^2np^5$  (ii) Fluorine, chlorine, bromine, iodine (iii) Astatine (iv) Fluorine and chlorine are gases, bromine is liquid and iodine is solid. (v) Fluorspar (CaF2); cryolite (Na3AlF6) (vi) Hypochlorous acid (HClO), Chlorous acid (HClO2); Chloric acid (HClO3); Perchloric acid (HClO<sub>4</sub>) (vii) Fluorine (viii) Chlorine dioxide, ClO<sub>2</sub> (ix) Cl<sub>2</sub>O (+1), HCl (-1), ClF<sub>3</sub> (+3), ClO<sub>2</sub> (+4), HClO<sub>3</sub> (+5), Cl<sub>2</sub>O<sub>6</sub> (+6), HClO<sub>4</sub> (+7) (x) chlorine (xi) Fused anhydrous potassium hydrogen fluoride (KHF2) (xii) Freon (CF2Cl2)

           SO_2 + Cl_2 + 2H_2O \longrightarrow H_2SO_4 + 2HCl
           3Br_2 + 3Na_2CO_3 \longrightarrow 5NaBr + NaBrO_3 + 3CO_2
    (xiv)
                     (Conc. and hot)
    (xv) CaOCl_2 + 2CH_3COOH + 2KI \longrightarrow
                                         (CH_3COO)_2Ca + 2KCl + I_2 + H_2O
7. (a) HCIO < HCIO_2 < HCIO_3 < HCIO_4
      (b) HCIO < HCIO_2 < HCIO_3 < HCIO_4
      (c) HClO_4 < HClO_3 < HClO_2 < HClO
      (d) F^- < Cl^- < Br^- < l^-
      (e) HI < I_2 < ICI < HIO_4
      (f) HOI < HOBr < HOCl < HOF
      (g) I_2 < Br_2 < Cl_2 < F_2
      (h) HF < HCl < HBr < HI
      (i) I < Br < Cl < F
      (i) I < Br < F < Cl
                                                  Laboratory agent
     (i)
             Muriatic acid
                                    HCl
                                                  As an acid
      (ii)
                                                  As a refrigerant
                 Freon
                                  CF<sub>2</sub>Cl<sub>2</sub>
      (iii)
              Hypo soln.
                                                  (i) Used in photography
                                 Na_2S_2O_3
                                                  (ii) As a volumetric reagent
```

```
manufacture of iodine
     (vi) Bleaching powder CaOCl2
                                              As a bleaching agent and
9. (i) (a) By heating conc. HCl with manganese dioxide.
               MnO_2 + 4HCl \longrightarrow MnCl_2 + 2H_2O + Cl_2
     (b) By doing electrolysis of NaCl solution.
     (c) By treating KClO3 with iodine.
                 2KClO_3 + I_2 \longrightarrow 2KIO_3 + Cl_2
     (d) Bleaching powder is treated either with mineral acids or CO<sub>2</sub>.
            CaOCl_2 + H_2SO_4 \longrightarrow CaSO_4 + H_2O + Cl_2
              CaOCl_2 + CO_2 \longrightarrow CaCO_3 + Cl_2
      (ii) (a) By heating mixture containing NaBr and NaBrO3 with
              hydrochloric acid.
               5\text{NaBr} + \text{NaBrO}_3 + 6\text{HCl} \longrightarrow 6\text{NaCl} + 3\text{Br}_2 + 3\text{H}_2\text{O}
      (b) By heating HBr with MnO<sub>2</sub>
               MnO_2 + 4HBr \longrightarrow MnBr_2 + Br_2 + 2H_2O
          or by passing Cl2 through HBr.
                  Cl_2 + 2HBr \longrightarrow 2HCl + Br_2
      (c) By heating KBr with MnO2 and conc. H2SO4 or by passing
          Cl2 through KBr solution.
      (iii) (a) By heating mixture of KI and MnO<sub>2</sub> with conc. H<sub>2</sub>SO<sub>4</sub> or
              by treating KI with H2O2.
                         2KI + H_2O_2 \longrightarrow 2KOH + I_2
          (b) Sodium iodate is treated with calculated quantity of sodium
              bisulphite.
        2NaIO_3 + 5NaHSO_3 \longrightarrow 3NaHSO_4 + 2Na_2SO_4 + H_2O + I_2
          (c) By passing Cl2 through HI.
                    2HI + Cl_2 \longrightarrow 2HCl + I_2
10. (i) Cl = +1, F = -1 (ii) I = +1, Cl = -1 (iii) Cl = -1 (iv) Cl = 0
      (v) +5 (vi) Cl = +7 (vii) Cl = +3 (viii) Cl = +1 (ix) F = -1
11. (i) Angular, sp^3 hybridization of Cl-atom
     (ii) Pyramidal, sp<sup>3</sup> hybridization of Cl-atom
    (iii) Pentagonal bipyramidal, sp^3d^3 hybridization of I-atom
    (iv) Linear, sp^3d hybridization of I-atom
     (v) Square planar, sp^3d^2 hybridization of I-atom
    (vi) V-shaped, sp<sup>3</sup> hybridization of O-atom
    (vii) T-shaped, sp^3d hybridization of I-atom
   (viii) Angular, sp^3d hybridization of Cl-atom.
12. See text
13. See text
15. (i) In presence of moisture (ii) On exposure to direct sunlight
      (iii) When NaOH solution is cold and dilute (iv) When NaOH
      solution is concentrated and hot (v) In diffused sunlight (vi) When
      NH3 is in excess (vii) When Cl2 is passed over dry slaked lime
      (viii) When KI is present (ix) When both are dry.
16. The black powder is MnO<sub>2</sub> and greenish-yellow gas is chlorine.
   MnO_2 + 2NaCl + 3H_2SO_4 \longrightarrow 2NaHSO_4 + MnSO_4 + Cl_2 + 2H_2O
                 3Cl_2 + 8NH_3 \longrightarrow N_2 + 6NH_4Cl
                3Cl_2 + 6KOH \longrightarrow KClO_3 + 5KCl + 3H_2O
           2KClO_3 + [MnO_2] \longrightarrow 2KCl + 3O_2 + [MnO_2]
```

17. The salt is NaCl and the evolved gas is HCl.

$$NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl$$

$$HCl + Blue litmus \longrightarrow Red litmus$$

$$HCl + NH_3 \longrightarrow NH_4Cl$$

$$White fumes$$

$$HCl + AgNO_3 \longrightarrow AgCl + HNO_3$$

$$White ppt.$$

$$2NaCl + MnO_2 + 3H_2SO_4 \longrightarrow 2NaHSO_4 + MnSO_4 + 2H_2O + Cl_2$$

$$Cl_2 + 2KI \longrightarrow 2KCl + I_2$$

$$Turns starch iodide paper blue.$$

$$18. The compound (X) is bleaching powder, CaOCl_2.$$

$$(i) CaOCl_2 + 2CH_3COOH + 2KI \longrightarrow Ca(CH_3COO)_2 + 2KCl + H_2O + I_2$$

$$(ii) CaOCl_2 + CO_2 \longrightarrow CaCO_3 + Cl_2$$

$$(iii) Ca(OCl)Cl + H_2O \longrightarrow Ca(OH)_2 + Cl_2$$

```
C_2H_5OH + Cl_2 \longrightarrow CH_3CHO + HCl
               CH<sub>3</sub>CHO + 3Cl<sub>2</sub> → CCl<sub>3</sub>CHO + 3HCl
           2CCl<sub>3</sub>CHO + Ca(OH)<sub>2</sub> ---- 2CHCl<sub>3</sub> + (HCOO)<sub>2</sub>Ca
19. The compound is BaCl<sub>2</sub>.
                BaCl<sub>2</sub> + H<sub>2</sub>SO<sub>4</sub> -
                                           \rightarrow BaSO<sub>4</sub> + 2HCl
                                              White ppt.
           2BaCl_2+ K_2Cr_2O_7 + 3H_2SO_4 \longrightarrow
                                          K_2SO_4 + 2CrO_2Cl_2 + 2BaSO_4 + 3H_2O
             CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O

## ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. The property of halogen acids, that indicated incorrect is: (a) HF > HCl > HBr > HI . . . . acidic strength (b) HI > HBr > HCl > HF . . . . reducing strength (c) HI > HBr > HCl > HF . . . . bond length (d) HF > HCl > HBr > HI . . . . thermal stability [Hint: HI is the strongest acid while HF is the weakest acid. The order of acidic strength is: HI > HBr > HCl > HF ] 2. The property of halogens, that indicated incorrect is:
- - (a)  $F > Cl > Br > I \dots$  ionisation energy
  - (b)  $F > Cl > Br > I \dots$  electron affinity
  - (c)  $F > Cl > Br > I \dots$  electronegativity
  - (d)  $I > Br > Cl > F \dots$  density in liquid state

[Hint: The electron affinity of Cl is maximum. The trend is: Cl > F > Br > I

- 3.  $I_4O_9$  is a/an:
  - (a) covalent compound
- (b) coordinate compound
- (c) ionic compound
- (d) double salt

Ans. (c)

[Hint: I4O9 is actually I(IO3)3 which gets ionised.

$$I(IO_3)_3 \rightleftharpoons I^{3+} + 3(IO_3)^- ]$$
Cold and dilute NaOH  $\rightarrow$  (A) + NaCl + H<sub>2</sub>O

Hot and conc. NaOH  $\rightarrow$  (B) + NaCl + H<sub>2</sub>O

Compounds (A) and (B) are:

- (a) NaClO<sub>3</sub>, NaClO
- (b) NaOCl<sub>2</sub>, NaOCl
- (c) NaClO<sub>4</sub>, NaClO<sub>3</sub>
- (d) NaOCl, NaClO<sub>3</sub>

Ans. (d)

[Hint: 
$$Cl_2 + 2NaOH \longrightarrow NaCl + NaOCl + H_2O$$
  
Cold and dil. (A)

$$3Cl_2 + 6NaOH \longrightarrow 5NaCl + NaClO_3 + 3H_2O$$
 ]

- 5. When chlorine water is added to an aqueous solution of sodium halide in the presence of chloroform, a violet colouration is obtained. When more of chlorine water is added, the violet colour disappears and solution becomes colourless. This confirms that sodium halide is :
  - (a) chloride
- (b) fluoride
- (c) bromide
- (d) iodide

Ans: (d)

 $\begin{array}{c} 2NaI + Cl_2 \longrightarrow 2NaCl + I_2 \text{ (violet colouration);} \\ I_2 + 5Cl_2 + 6H_2O \longrightarrow 2HIO_3 + 10HCl] \end{array}$ Hint:

- 6. As the atomic number of the halogens increases, the
  - (a) lose the outermost electrons less readily
  - (b) become less dense
  - (c) become lighter in colour
  - (d) gain electrons less readily

[Hint: The electron affinity decreases down the group as atomic size increases.]

- 7. The halogen that is most readily reduced is:
  - (a) fluorine
- (b) chlorine
- (c) bromine
- (d) iodine

Ans. (a)

[Hint: The reduction potential of fluorine is maximum and thus, it is easily reduced, i.e., it acts as strongest oxidising agent.]

- 8. Which has maximum pH in aqueous solution?
  - (a) NaClO
- (b) NaClO<sub>2</sub>
- (c) NaClO<sub>3</sub>
- (d) NaClO<sub>4</sub>

Ans. (a)

[Hint: NaClO+H2O \rightarrow NaOH + HClO; HClO is the weakest acid among the oxyacids of chlorine and thus, the solution of NaClO has maximum pH.1

				, ,	
9.	In the known interhalogen compounds, the maximum number of halogen atoms are:  (a) 4 (b) 8  (c) 5 (d) 7  Ans. (b)	15.	What products are experienced reaction of hypochlorous action (a) HClO <sub>3</sub> and Cl <sub>2</sub> O (c) HCl and Cl <sub>2</sub> O Ans. (d)	cid? [A.I.E.E. 20 (b) HClO <sub>2</sub> and HClO <sub>4</sub> (d) HCl and HClO <sub>3</sub>	
10.	shaking chlorine water with freshly precipitated yellow oxide of mercury?  (a) HClO <sub>3</sub> (b) HClO <sub>2</sub> (c) HClO (d) HClO <sub>4</sub> Ans. (c)  [Hint: HgO + 2Cl <sub>2</sub> + H <sub>2</sub> O	16.	[Hint: 3HClO \to HClO_3 + The number of lone pairs of e of ClF_3 is:  (a) 0 (b) 1  Ans. (c)  [Hint: Cl in first excited state	electrons present in central at [J.E.E. (Orissa) 20 (c) 2 (d) 3 $3d$	
11.	The substance, which is solid at room temperature, forms ionic compounds and reacts with hydrogen forming a hydride, the aqueous solution of which is acidic, may be:  (a) Al  (b) Na  (c) I <sub>2</sub> (d) Br <sub>2</sub>	17.		g agent because it has: [M.P.(P.M.T.) 20	/
12.	[Hint: Iodine is a solid at room temperature, can form ionic compounds. It forms HI with hydrogen which is an acid in aqueous solution.]  Interhalogen compounds are more reactive than the individual halogen because:  (a) two halogens are present in place of one (b) their bond energy is less than the bond energy of the		When $F_2$ reacts with hot and be obtained: (i) $OF_2$ (ii) $O_2$ (iii) $H_2O$ (a) (i), (iii) and (iv) (c) (ii), (iii) and (iv) Ans. (c) [Hint: $4NaOH + 2F_2 \longrightarrow 4$	conc. alkali, then following v [M.H.(C.E.T.) 20 (iv) NaF (b) (ii) and (iii) only (d) all of these	will
13.		19.	The hybridization present in (a) $sp^3d$ (c) $sp^3d^2$ Ans. (a)	in IF <sub>3</sub> is: [P.M.T. (Raj.) 20 (b) $sp^3$ (d) $sp^3d^3$	<del>105</del> ]
14.	<ul> <li>(a) aqueous solution of I<sub>2</sub></li> <li>(b) solution of iodine in aqueous KI</li> <li>(c) alcoholic solution of I<sub>2</sub></li> <li>(d) aqueous solution of KI</li> <li>Ans. (b)</li> <li>Which two of the following substances are used for</li> </ul>	20.	Shape of ClF <sub>3</sub> is:  (a) equilateral triangle  (c) V-shaped  Ans. (d)	(b) pyramidal (d) T-shaped	107]
	preparing iodized salt?  (i) KIO <sub>3</sub> (ii) KI (iii) I <sub>2</sub> (iv) HI  (a) (i) and (ii) (b) (i) and (iii)  (c) (ii) and (iv) (d) (iii) and (iv)  Ans. (a)	21.	Predict the product of the form $Cl_2 + HgO \longrightarrow$ (a) $HgCl_2 + O_2$ (c) $HgCl_2 + Cl_2O$ Ans. (c)	. =	107]

# JECTIVE QUESTIONS

set.	1: This set contains qu	iestions with only one corr	ect an	iswer	•		
1.	Halogens are:			14.	The solubility of iodine	in H <sub>2</sub> O may be increased by	the
	(a) gases under ordinary	conditions			addition of:		
	(b) electronegative in nat	ure			(a) $Na_2S_2O_3$	☐ (b) CHCl <sub>3</sub>	
	(c) fuming liquids				(c) KI	$\Box$ (d) $CS_2$	
	(d) the gases found in at	mosphere		15.	The colour of iodine solu	tion is discharged by shaking	with:
2.	Halogens show usually:	_			(a) aqueous sulphur diox		
	(a) electro-valency				(b) sodium sulphide		
	(b) covalency				(c) sodium sulphate	☐ (d) sodium chloride	
	- · · ·	and_covalency		16.	• •	through concentrated hot sol	ution
	(d) coordinate valency	-			of KOH, the compound f		
3.	The most powerful oxidisi	ng agent is: [C.B.S.E. (P.M.T.) 20	109]		(a) KClO	□ (b) KClO <sub>2</sub>	
		☐ (b) chlorine			(c) KClO <sub>3</sub>	☐ (d) KClO <sub>4</sub>	
	(c) bromine	☐ (d) iodine		17.	• •	he laboratory by the action of	:
4.	How many electrons are	present in the outermost orbi	t of		(a) Zn and HCl	☐ (b) CaCO <sub>3</sub> and HCl	
	halogens?				(c) Pb(NO <sub>3</sub> ) <sub>2</sub> and HCl	☐ (d) MnO <sub>2</sub> and HCl	
	(a) 1	□ (b) 3		18.	Which among the follow		
	(c) 5	□ (d) 7		10.	(a) Cl <sub>2</sub> O <sub>7</sub>	(b) Cl <sub>2</sub> O <sub>6</sub>	
5.	Which one of the hydrac	ids does not form any precipi	tate		(a) Cl <sub>2</sub> O <sub>7</sub> (c) ClO <sub>2</sub>	☐ (d) Cl <sub>2</sub> O <sub>6</sub>	
	with AgNO <sub>3</sub> ?			10	Pure chlorine is obtained		
	(a) HF	☐ (b) HCl		17.		1.	
	(c) HBr	□ (d) HI			(a) by heating PtCl <sub>4</sub>	th HCl	
6.	The strongest reducing a	gent is:			(b) by heating MnO <sub>2</sub> wit		
	(a) F <sup>-</sup>	□ (b) Cl <sup>−</sup>			(c) by treating bleaching	<del>-</del>	
	(c) Br	□ (d) I <sup>-</sup>		20		NaCl and MnO <sub>2</sub> with conc.H <sub>2</sub> S	$O_4$ $\square$
7.	Which one of the follow	ing is the strongest acid?		20.	Chlorine gas is dried over		J===-4
	(a) HF	□ (b) HI			(a) CaO	□ (b) NaOH	
	(c) HBr	☐ (d) HCl		•	(c) H <sub>2</sub> SO <sub>4</sub>	☐ (d) HBr	
8.	Which one of the follows	ng is the most volatile acid?		21.		aCl, K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> and conc. H <sub>2</sub> SO <sub>4</sub>	•••••
	(a) HF	☐ (b) HCl			is obtained.		
	(c) HBr	□ (d) HI			(a) chromic chloride	(b) chromyl chloride	
9.	The acid which cannot b	e kept in glass bottles is:			(c) chlorine	$\Box$ (d) none of these	
	(a) HI	□ (b) HBr		22.	-	the Deacon's process for	the
	(c) HF	☐ (d) HCl			manufacture of chlorine		
10.	Which one of the follow	ing is the strongest acid?			(a) Cu	☐ (b) An alloy of copper	
	(a) HClO	☐ (b) HClO <sub>2</sub>			(c) CuCl <sub>2</sub>	□ (d) CuS	
	(c) HClO <sub>3</sub>	☐ (d) HClO <sub>4</sub>		23.	Which one of the follow	ving acts as an antichlor?	
11.	Which one of the following	ng is the strongest oxidising ag	ent?		(a) MnO <sub>2</sub>	$\Box$ (b) Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub>	
	(a) HClO	☐ (b) HClO <sub>2</sub>		ş	(c) $K_2Cr_2O_7$	☐ (d) Na <sub>2</sub> SO <sub>4</sub>	
	(c) HClO <sub>3</sub>	☐ (d) HClO <sub>4</sub>		24.	One gas bleaches the c	colour of flowers by reduction	n and
12.	Consider the following of	xides:			other by oxidation. The	se gases are:	
	1. OF <sub>2</sub> 2. Cl <sub>2</sub> O 3. Br <sub>2</sub> O	)			(a) SO <sub>2</sub> and Cl <sub>2</sub>	☐ (b) CO and Cl <sub>2</sub>	
	The correct sequence of	X—O—X bond angle is:			(c) NH <sub>3</sub> and SO <sub>2</sub>	(d) H <sub>2</sub> S and Br <sub>2</sub>	
	(a) $1 > 2 > 3$	$\Box$ (b) 3 > 2 > 1		25.	Bromine occurs as a bro		
	(c) $2 > 1 > 3$	$\Box$ (d) 1 > 3 > 2			(a) nitre	☐ (b) tincal	
	[Hint: O	o: •o•	]		(c) common salt	☐ (d) carnallite	
	1100	1050		26.	Bromine is prepared in t		
	Br Br	Cl Cl F	F		(a) by heating KBr with	•	
13.	Which one of the follow	ing has hydrogen bonding?			•	$MnO_2$ with conc. $H_2SO_4$	
	(a) HI	☐ (b) HBr			(c) by heating KBr with	_	
	(c) HF	☐ (d) HCl				ars through KBr solution	
				1	(a) by passing 12 vapou	us amongu voi sommon	

27.	Caliche is:	40.	A substance $X$ when heated with conc. $H_2SO_4$ liberates	a
	(a) impure nitre $\Box$ (b) impure carnallite $\Box$		gas which turns starch paper blue. The substance $X$ is:	
	(c) crude saltpetre $\Box$ (d) ashes of sea-weeds $\Box$		(a) NaI	
28.	Iodine is manufactured from:		(c) NaCl	
	(a) sea-weeds $\Box$ (b) carnallite $\Box$	41.	The chemical name of bleaching powder is:	
	(c) nitre $\Box$ (d) pure sodium iodide $\Box$		- 1 - 1 - 1 - 1 - 1 - 1 - 1 - 1 - 1 - 1	
29.	Iodine displaces chlorine from which one of the compounds:	Ì	(b) calcium chlorohypochlorite	
	(a) KCl		• •	
	(c) $CCl_4$			
30.	Elements of which one of the following groups will form	42.	Identify the correct statements:	
	anions most readily?		1. On heating Rb(ICl <sub>2</sub> ) will decompose giving RbCl and IC	Č1.
	(a) Oxygen group $\Box$ (b) Nitrogen group $\Box$		2. CsI <sub>3</sub> will ionise to give Cs <sup>+</sup> and $I_3^-$ .	
	(c) Halogens		3. KBrICl will give KCl and IBr on heating.	
31	Which statement is correct about halogen?		4. In the reaction $I^- + I_2 \longrightarrow I_3^-$ , the Lewis acid is $I_2$ .	
<i>J</i> 1.	(a) They are all diatomic and form univalent ions			
	(b) They are all capable of exhibiting several oxidation states			
	(b) They are an eapable of exhibiting several oxidation states		[Hint: $CsI_3 \longrightarrow Cs^+ + I^- + I_2$ ]	
		43	Oxidising action increases in the following order:	
				-=
22	(-) 2)	1		
32.	Fluorine is the best oxidising agent because:	1 44	Fluorine does not show positive oxidation state because	
	(a) it has the highest electron affinity	TT.	-	
	(b) it has the highest electronegativity		• •	
	(c) it has the highest $E_{ox}^{o}$	1	` ,	
22	(d) it has the highest $E_{red}^{o}$		``	
33.	Iodine vapours are violet in colour because:	15	(2) 15 1110 110 11 01011111	
	(a) the molecules of iodine in vapour phase absorb green	43.	Available chlorine is liberated from bleaching powder who	
	and yellow radiations		(a) it is heated	
	(b) the molecules of iodine absorb red and violet radiations			
	and then emit them		(-)	
2.4	(c) it is a solid	1	(d) it is reacted with water	
34.	Among the elements of group 17, fluorine is the most reactive	46.	Bromine can be liberated from potassium bromide soluti	on
	owing to its:		by the action of:	_
	(a) electronegativity			
	(b) small size		( ) 1	
	(c) extremely high oxidising power and low dissociation	47.	Which of the following is not oxidised by MnO <sub>2</sub> ?	
	energy of F—F bond			
	(d) all the above factors are responsible for high reactivity	ļ	(c) $Br^ \Box$ (d) $I^-$	
~~	of fluorine		[Hint: The fluoride ion: F: is extremely stable. Hence, it is	not
35.	Which one of the following reacts with chlorine to form		oxidised by chemical reagents.]	
	phosgene?	48.	Bleaching properties of bleaching powder are due to its:	
	(a) $SO_2$	10.		_
26	(c) NO			H
36.	Which of the following elements does not show positive	1. 40	(c) basic properties	
	oxidation state?	49.	Which one of the following halogens is purified	bу
	(a) Fluorine		sublimation?	_
	(c) Oxygen $\square$ (d) Sulphur $\square$	}	(a) F	
37.	Slaked lime reacts with chlorine to form:		(c) Br	
	(a) $Ca(OCl)_2$ $\Box$ (b) $Ca(OCl)Cl$ $\Box$	50.	In a given sample of bleaching powder, the percentage	
	(c) $Ca(ClO_3)_2$ $\Box$ (d) $CaCl_2$ $\Box$		available chlorine is 49. The volume of chlorine obtained	l if
38.	Iodine is liberated from KI solution when treated with:		10 g of the sample is treated with HCl at N.T.P. is:	_
	(a) $ZnSO_4$ $\Box$ (b) $CuSO_4$ $\Box$		(a) 1.5 litre	
	(c) $NiSO_4$ $\Box$ (d) $FeSO_4$ $\Box$		(c) 15.0 litre	
39.	Iodine may be liberated from sodium iodate by reacting with:	51.	Conc. H <sub>2</sub> SO <sub>4</sub> is not used to prepare HBr from KBr because	
-	(a) $H_2SO_4$ $\Box$ (b) $NaHSO_3$ $\Box$		(a) reacts too slowly with KBr	
	(c) $\overline{\text{KMnO}_4}$ $\square$ (d) $\overline{\text{HCl}}$ $\square$		(b) reduces HBr	
	- · · · · · · · · · · · · · · · · · · ·			

		.494	and the state of t	
	(c) oxidises HBr	1	(a) fluorine	
	(d) oxidises KBr to KBrO <sub>3</sub> $\Box$		(c) bromine $\Box$ (d) iodine	
52.	Which one of the following is the strongest acid?	66.	When I2 is passed through solutions of KCl, KF and I	KBr
	(a) $SO(OH)_2$ $\Box$ (b) $SO_2(OH)_2$ $\Box$		respectively: [C.E.E.T. (Haryana) 20	000]
	(c) $CIO_2(OH)$ $\Box$ (d) $CIO_3(OH)$ $\Box$		(a) Cl <sub>2</sub> and Br <sub>2</sub> are evolved	
53.	Which of the following is the anhydride of perchloric acid?		(b) Cl <sub>2</sub> is evolved	
	(a) $Cl_2O$ $\Box$ (b) $ClO_2$ $\Box$	1.	(c) Cl <sub>2</sub> , Br <sub>2</sub> and F <sub>2</sub> are evolved	
٠.	$\Box$ (c) $\Box$ $\Box$ (d) $\Box$ $\Box$		(d) none of the above	
54.	HBr and HI can reduce H <sub>2</sub> SO <sub>4</sub> , HCl can reduce KMnO <sub>4</sub> and	67.	Iodine deficiency in diet is known to cause:	
*	HF can reduce:		(a) beri-beri	
	(a) $K_2Cr_2O_7$		(c) rickets	
	(c) $H_2SO_4$ $\square$ (d) none of these $\square$	68.	Chlorine is mixed with drinking water so that:	
55.	Chlorine acts as a bleaching agent only in the presence of:	00.	(a) bacteria are killed $\Box$ (b) dirt is removed	
	(a) dry air		•	
	(c) moisture $\Box$ (d) pure oxygen $\Box$	60	**	
56.	Which of the following pairs is not correctly matched?	69.	Which of the following has the greatest reducing power	
	(a) A halogen which is liquid at room temperature—Bromine	•	(a) HBr	
		70	(c) HCl	
•	(b) The most electronegative element—Fluorine □	/0	Concentrated HNO <sub>3</sub> reacts with iodine to give:	
	(c) The most reactive halogen—Fluorine		(a) HI	
	(d) The strongest oxidising agent— <i>lodine</i>		(c) $HOIO_2$	
57.	Which of the following statements is correct for CsBr <sub>3</sub> ?	71.	The correct order of increasing bond angles in the follow	ving
	(a) It is a covalent compound		species is :	
	(b) It contains Cs³+ and Br⁻ ions □		(a) $Cl_2O < ClO_2 < ClO_2^ \square$ (b) $ClO_2 < Cl_2O < ClO_2^-$	
	(c) It contains Cs <sup>+</sup> and Br <sub>3</sub> ions		(c) $Cl_2O < ClO_2^- < ClO_2$ $\Box$ (d) $ClO_2^- < Cl_2O < ClO_2$	
	(d) It contains $Cs^+$ , $Br^-$ and lattice $Br_2$ molecule	72.	Which of the following is not a pseudohalide ion?	
58.	Which of the following is most stable towards heat?		(a) SCN <sup>-</sup>	
	(a) HCl		(c) $ICl_2^-$	
	(c) HBr	73.	The following acids have been arranged in order	of
59.	The silver halide, which is least soluble in NH <sub>4</sub> OH is:		decreasing acid strength. Identify the correct order:	
	(a) AgF		ClOH(I) BrOH(II) IOH(III)	
	(c) $AgBr$ $\Box$ (d) $AgI$ $\Box$		(a) $I > II > III$	
60.	Fluorine reacts with water to give:		(c) $III > II > I$ $\Box$ (d) $I > III > II$	
	(a) hydrogen fluoride and oxygen □	74.	The acid employed for etching of glass is:	
	(b) hydrogen fluoride and ozone		(a) $H_2SO_4$ $\Box$ (b) $HClO_4$	
	(c) hydrogen fluoride and oxygen fluoride		(c) HF	
	(d) hydrogen fluoride, oxygen and ozone	75.	Hydrogen fluoride is a liquid unlike other hydrogen hali	
61.	When bleaching powder is treated with carbon dioxide:		because:	<b>u</b> 00,
	(a) chlorine is evolved		(a) H—F bond is strong	
	(b) calcium chloride is formed $\Box$		(b) F-atom is small in size	
	(c) no reaction occurs	-	(c) Hydrogen bonding is present	
	(d) it absorbs the gas		(d) HF is a weak acid	
62.	Bleaching powder is an example of:	76		
	(a) an acidic salt	/0.	Hydrogen bromide is dried by passing the gas through	
	(c) a double salt $\Box$ (d) a mixed salt $\Box$		(a) quick lime	
63.	The outermost electronic configuration of the most electro-		(b) anhydrous calcium chloride	
	negative element is:		(c) potassium hydroxide pellets	
	(a) $ns^2np^3$ $\Box$ (b) $ns^2np^4$ $\Box$		(d) conc. H <sub>2</sub> SO <sub>4</sub>	
	(c) $ns^2np^5$ $\Box$ (d) $ns^2np^6$ $\Box$	77.		
64.	Among the halogens, the one which is oxidised by nitric acid	1	(a) fluorine	
	is: [C.E.E.T. (Haryana) 2005]		(c) chlorine	
	(a) fluorine $\Box$ (b) chlorine $\Box$	78.	3	
	(c) bromine $\Box$ (d) iodine $\Box$		(a) $ClO_4^-$	
65.			(c) ICl and $O_3$ $\square$ (d) $IO_3^-$ and $Cl_2$	
	besides zero:		[Hint: $ClO_3 + I_2 \longrightarrow 2lO_2 + Cl_2$ ]	

79.	Which of the following is a preparation of chlorine?	92.	The structure of IF <sub>7</sub> is:	
	(a) HCl acting on KMnO <sub>4</sub> $\square$ (b) HCl acting on Na <sub>2</sub> O <sub>2</sub> $\square$		(a) trigonal bipyramid	
	(c) Electrolysis of brine $\Box$ (d) All of these $\Box$		(c) pentagonal bipyramid   (d) tetrahedral	
80.	The shape of $O_2F_2$ is similar to : [A.I.I.M.S. 2004]	93.	Which of the following is the strongest acid?	
	(a) $H_2O_2$ $\square$ (b) $C_2F_2$ $\square$		(a) HBr	
	(c) $H_2F_2$ $\square$ (d) $C_2H_2$ $\square$		(c) $H_2S$	
81.	Bleaching powder is obtained by the interaction of chlorine	94.	Which of the following has the highest value of dip	ole
	and:		moment?	
	(a) dilute solution of $Ca(OH)_2$		(a) HCl (b) HF	
	(b) concentrated solution of $Ca(OH)_2$		(c) HI	
	(c) dry calcium oxide $\Box$ (d) dry slaked lime $\Box$	95.	A radioactive halogen is:	
82.	Which amongst the following reactions cannot be used for		(a) polonium	-
	the respective preparation?		(c) astatine	
	(a) $2KBr + H_2SO_4$ (conc.) $\longrightarrow K_2SO_4 + 2HBr$	- 96.	Which of the following compounds contains both chlor	rine
	(b) NaCl + $H_2SO_4$ (conc.) $\longrightarrow$ NaHSO <sub>4</sub> + HCl		and fluorine?	
	(c) $NaHSO_4 + NaCl \longrightarrow Na_2SO_4 + HCl$		(a) teflon	
	(d) $CaF_2 + H_2SO_4 \longrightarrow CaSO_4 + 2HF$		(c) freon	
02		97.	Which is formed when K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> , CaCl <sub>2</sub> and conc. H <sub>2</sub> SO <sub>4</sub>	are
83.	Which of the following possesses the highest bond energy?	:	heated?	
	(a) $F_2$		(a) $Cr_2(SO_4)_3$ $\square$ (b) $CrCl_3$	
D/I	- (-) -2		(c) $CrO_2Cl_2$ $\square$ (d) $K_2CrO_4$	
84.	Astatine is the element below iodine in the group VIIA of	98.	Chlorine water on cooling deposits greenish-yellow crys	tals
	the periodic table. Which of the following statements is not		of:	
	true for astatine?		(a) $Cl_2 \cdot 2H_2O$ $\Box$ (b) $Cl_2 \cdot H_2O$	
	(a) It is less electronegative than iodine		(c) Cl <sub>2</sub> ·3H <sub>2</sub> O	
	(b) It will exhibit only -1 oxidation state	99.	A white deposit forms over the bottles containing conc. I	HC1
	(c) Intermolecular forces between the astatine molecules will		when kept for a long time in the laboratory. The wl	
	be larger than between iodine molecules  (d) It is composed of diatomic molecules		deposit is due to the formation of:	
05	(-)		(a) ammonium chloride	
85.	Order of boiling point is: [D.P.M.T. 2005]		(c) sodium carbonate	
	(a) HF > HI > HBr > HCl □ (b) HF > HBr > HI > HCl □	100.	Dry Cl <sub>2</sub> reacts with dry SO <sub>2</sub> to form:	
			(a) thionyl chloride	
	(-)		(c) sulphur dichloride	e□
04		101.		
86.	Halogens exist in $-1$ , $+1$ , $+3$ , $+5$ and $+7$ oxidation states.		(a) dry conditions $\square$ (b) presence of HCl only	
	The halogen that exists only in -1 oxidation state is:		(c) moist conditions	
	[P.E.T. (Kerala) 2010] (a) I	102.	Which of the following statements is correct?	
			[B.H.U. 19	997]
07			(a) All halogens form oxyacids	
87.			(b) Only chlorine and bromine form oxyacids	
	\ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \ \		(c) All halogens except fluorine form oxyacids	
00	( ) #		(d) Only iodine forms oxyacid	
88.	Which of the following polyhalides is not known?	103.	Which of the following statements is not correct whe	en a
	(a) $Cl_3$		mixture of NaCl and K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> is gently warmed with co	
90	( ) 3		$H_2SO_4$ ?	
89.	The iodine atom in $ICl_2^-$ involves: (a) $sp_3^3d$ hybridization $\square$ (b) $sp_3^3d^2$ hybridization $\square$		(a) A deep red vapour is evolved	
	(a) $sp^3d$ hybridization $\square$ (b) $sp^3d^2$ hybridization $\square$ (c) $sp^2$ hybridization $\square$ (d) $sp^3$ hybridization $\square$		(b) The vapour when passed into NaOH solution give	es a
00	When the vapours of chromyl chloride are passed through		yellow solution of Na <sub>2</sub> CrO <sub>4</sub>	
90.	· · · · · · · · · · · · · · · · · · ·		(c) Chlorine gas is evolved	
	NaOH solution, it turns yellow. This is due to formation of:		(d) Chromyl chloride is formed	
	(a) $Na_2Cr_2O_7$	104.		
Ω1	(c) CrO <sub>3</sub>		3NaClO Heat NaClO <sub>3</sub> + 2NaCl	
91.	2		(a) It is a disproportionation reaction	
	(a) pentagonal bipyramid (b) trigonal bipyramid (c) entabodies (d) tetrahedral		(b) Oxidation number of chlorine decreases as well	_
	(c) octahedral $\Box$ (d) tetrahedral $\Box$		increases in this reaction	

	(c) This reaction is used for the manufacture of halates E	]	(a) $Na_2S_4O_6$	
	(d) All of the above	]	(c) NaCl	
105.	On heating KClO <sub>3</sub> we get: [C.P.M.T. 1999	]	[Hint: $Na_2S_2O_3 + 4Cl_2 + 5H_2O \longrightarrow 2NaHSO_4 + 8HCl$ ]	
	(a) $KClO_2 + O_2$	1112.	Shape and hybridisation of IF <sub>5</sub> respectively are:	
	(c) $KCl + O_3$	]	[J.E.E. (Orissa) 200	08]
106.	The correct order of thermal stability of hydrogen halide	s	(a) trigonal bipyramidal, $sp^3d$	
	(H-X) is: [A.I.E.E.E. 2005]	1	. 2	
	(a) HI>HBr>HCl>HF  (b) HF>HCl>HBr>HI	- 1	(c) square pyramidal, $sp^3d^2$	
	(c) $HCl > HF > HBr > HI \square$ (d) $HI > HCl > HF > HBr \square$		(d) pentagonal pyramidal, $sp^3d^3$	
107.	The set with correct order of acidity is: [LJ.T. (S) 2001			
107.	C.B.S.E. 2007	110.	$Na_2S_2O_3$ is reduced by $I_2$ to: [J.E.E. (Orissa) 200	
	(a) HClO < HClO <sub>2</sub> < HClO <sub>3</sub> < HClO <sub>4</sub>	<u>.</u>	(a) $Na_2S$ $\square$ (b) $Na_2SO_4$	
	(b) $HClO_4 < HClO_3 < HClO_2 < HClO$	- }	(5) 11425458	
	(c) $HClO_4 < HClO_3 < HClO_2 < HClO_2$ (c) $HClO_4 < HClO_3 < HClO_2$	1 1 1 21	The oxidation states of iodine in HIO <sub>4</sub> , H <sub>3</sub> IO <sub>5</sub> and H <sub>5</sub> IO <sub>5</sub>	$O_6$
	(-)	_	are respectively: [A.I.I.M.S. 200	08]
100	(4) 110104 (110103 (11010	-	(a) $+1, +3, +7$	
108.	The reaction,		(c) $+7, +7, +7$ $\square$ (d) $+7, +5, +3$	
	$3ClO^{-}(aq.) \longrightarrow ClO_{3}^{-}(aq.) + 2Cl^{-}(aq.)$	115.	The electron affinity values (in kJ mol <sup>-1</sup> ) of three haloge	ens
	is an example of: [I.I.T. (S) 2001	]	X, Y and Z are respectively -349, -333 and -325. X, Y and	
	(a) oxidation reaction $\Box$ (b) reduction reaction $\Box$		respectively are: [D.C.E. (Engg.) 200	
	(c) disproportionation	1	(a) $F_2$ , $Cl_2$ , $Br_2$	$\Box$ .
	(d) decomposition reaction	]	(c) $Cl_2$ , $Br_2$ , $F_2$	
109.	Hydrogen bond is strongest in: [B.V. (Pune) 2002	]   116	Which one of the following reactions does not occur?	
	(a) F—H—O	]   110.		 AO1
	(c) F—H—F	]	[E.A.M.C.E.T. (Engg.) 200	
110.	Which of the following has highest bond strength?		(a) $F_2 + 2Cl^- \longrightarrow 2F^- + Cl_2$	
	[C.E.E. (Bihar) 2002	:]	(b) $Cl_2 + 2F^- \longrightarrow 2Cl^- + F_2$	
	(a) HI	ן כ	(c) $Br_2 + 2\Gamma \longrightarrow 2Br^- + I_2$	
		1	AN CHARLES ACHE IN	
	(c) HF ☐ (d) HBr l	]	(d) $Cl_2 + 2Br^- \longrightarrow 2Cl^- + Br_2$	
111.	(0) 111	-	(d) $Cl_2 + 2Br \longrightarrow 2Cl + Br_2$	Ц
111.	(c) HF $\square$ (d) HBr $\square$ Aqueous solution of Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> on reaction with Cl <sub>2</sub> gives [1.1.T. 2008]	:	(d) $Cl_2 + 2Br \longrightarrow 2Cl + Br_2$	
	Aqueous solution of Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> on reaction with Cl <sub>2</sub> gives			ш
Set	Aqueous solution of Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> on reaction with Cl <sub>2</sub> gives [1.1.T. 2008]  II: This set contains questions with two or more contains	orrect and	swers.	
Set	Aqueous solution of Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> on reaction with Cl <sub>2</sub> gives [1.1.T. 2008]  II: This set contains questions with two or more companies with the following halogens turn(s) starch iodine paper.	orrect and	swers. (d) HClO <sub>4</sub> > HClO <sub>3</sub> > HClO <sub>2</sub> > HClO	
Set	Aqueous solution of Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> on reaction with Cl <sub>2</sub> gives [I.I.T. 2008] II: This set contains questions with two or more companies with two or more companies with the following halogens turn(s) starch iodine paper blue?	orrect and	swers.  (d) HClO <sub>4</sub> > HClO <sub>3</sub> > HClO <sub>2</sub> > HClO  The halogens, which are not attacked by conc. HNO <sub>3</sub> , a	are:
Set	Aqueous solution of Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> on reaction with Cl <sub>2</sub> gives  [I.I.T. 2008]  II: This set contains questions with two or more contains the following halogens turn(s) starch iodine papellue?  (a) Cl <sub>2</sub>	orrect and 124.	swers.  (d) $HClO_4 > HClO_3 > HClO_2 > HClO$ The halogens, which are not attacked by conc. $HNO_3$ , at (a) $F_2$ $\square$ (b) $Cl_2$	are:
<b>Set</b> 117.	Aqueous solution of $Na_2S_2O_3$ on reaction with $Cl_2$ gives  [1.1.T. 2008]  II: This set contains questions with two or more complete which of the following halogens turn(s) starch iodine papellule?  (a) $Cl_2$	orrect and 124.	swers.  (d) $HClO_4 > HClO_3 > HClO_2 > HClO$ The halogens, which are not attacked by conc. $HNO_3$ , at (a) $F_2$	are:

## **Objective Questions for IIT ASPIRANTS**

- 1. A greenish yellow gas reacts with an alkali metal hydroxide to form a halate which can be used in fireworks and safety matches. The gas and the halate are:
  - (a)  $Br_2$ ,  $KBrO_3$
- (b) Cl<sub>2</sub>, KClO<sub>3</sub>
- (c) I<sub>2</sub>, NaIO<sub>3</sub>
- (d)  $I_2$ ,  $KIO_3$

[Hint: The halate used in fireworks and safety matches is KClO<sub>3</sub>. Thus, the gas is Cl<sub>2</sub>.

$$3Cl_2 + 6KOH \longrightarrow KClO_3 + 5KCl + 3H_2O$$
 ]  
Greenish vellow gas

- 2. When chlorine water is added to an aqueous solution of sodium iodide in the presence of chloroform, a violet colouration is obtained. On adding more of chlorine water and vigorous shaking, the violet colour disappears. This shows the conversion of . . . . . into . . . . .
  - (a)  $I_2$ ,  $HIO_3$
- (b)  $I_2$ , HI
- (c) HI, HIO3
- (d) I<sub>2</sub>, HIO

[Hint:

$$Cl_2 + 2NaI \longrightarrow 2NaCl + I_2$$

(Violet colouration in chloroform)

$$5Cl_2 + 6H_2O + I_2 \longrightarrow 2HIO_3 + 10HCl$$
 ]

3. For  $(A) + K_2CO_3 + air \xrightarrow{Heat} (B)$ 

$$(B) + \operatorname{Cl}_2 \longrightarrow (C) \operatorname{pink}$$

Which of the following is correct?

- (a) (A) is black, MnO<sub>2</sub>; (B) is blue, K<sub>2</sub>MnO<sub>4</sub> and (C) is pink, KMnO<sub>4</sub>
- (b) (A) is green,  $Cr_2O_3$ ; (B) is yellow,  $K_2CrO_4$  and (C) is pink,  $K_2Cr_2O_7$
- (c) (A) is black, MnO<sub>2</sub>; (B) is green, K<sub>2</sub>MnO<sub>4</sub> and (C) is pink, KMnO<sub>4</sub>
- (d) (A) is black, Bi<sub>2</sub>O<sub>3</sub>; (B) is colourless, KBiO<sub>2</sub> and (C) is pink, KBiO<sub>3</sub>

- $[ \mbox{Hint}: \begin{tabular}{ll} MnO_2 + K_2CO_3 + \frac{1}{2}O_2 & \longrightarrow K_2MnO_4 + CO_2 \\ & (Air) & (B) \\ & Green \\ \hline & 2K_2MnO_4 + Cl_2 & \longrightarrow 2KMnO_4 + 2KCl \end{tabular} ]$
- 4. Euchlorine is:
  - (a) obtained by heating perchlorate with conc. HCl
  - (b) a chloride of europium
  - (c) a mixture of Cl<sub>2</sub> and Cl<sub>2</sub>O<sub>7</sub>
  - (d) a mixture of Cl2 and ClO2

[Hint: When KClO<sub>3</sub> is heated with conc. HCl, a mixture of Cl<sub>2</sub> and ClO<sub>2</sub> is formed. This mixture is known as euchlorine.  $2\text{KClO}_3 + 4\text{HCl} \longrightarrow 2\text{KCl} + 2\text{ClO}_2 + \text{Cl}_2 + 2\text{H}_2\text{O}]$ 

- 5. Which is incorrectly matched?
  - (a)  $CsBr_3 \rightleftharpoons Cs^+ + Br_3^- \rightleftharpoons Cs^+ + Br_2^- + Br_2$
  - (b)  $I_4O_9 \rightleftharpoons I^{3+} + 3(IO_3)^-$
  - (c)  $AgBrO_3 \rightleftharpoons Ag^+ + BrO_3^-$
  - (d)  $I_2O_4 \rightleftharpoons IO_2^+ + IO_2^-$

[Hint: 
$$I_2O_4 \rightleftharpoons I^+ + IO_4^-$$
]

- 6. A certain compound (X) when treated with copper sulphate solution yields a brown precipitate. On adding hypo solution, the precipitate turns white. The compound is:
  - (a) K<sub>2</sub>CO<sub>3</sub>
- (b) KI

(c) KBr

(d)  $K_3PO_4$ 

$$[\mbox{Hint}: \quad CuSO_4 + 2KI \longrightarrow CuI_2 + K_2SO_4 \, ; \\ 2CuI_2 \longrightarrow Cu_2I_2 + I_2 \, ; \\ \mbox{White} \quad \mbox{Brown} \label{eq:cuSO_4}$$

$$I_2 + 2Na_2S_2O_3 \longrightarrow Na_2S_4O_6 + 2NaI$$
 Colourless

7. The products of the chemical reaction between  $Na_2S_2O_3$ ,  $Cl_2$  and  $H_2O$  are :

(a) S, HCl, Na<sub>2</sub>SO<sub>4</sub>

(b) S, HCl, Na<sub>2</sub>S

(c) S, HCl, Na<sub>2</sub>SO<sub>3</sub>

(d) S, NaClO<sub>3</sub>

[Hint:  $Na_2S_2O_3 + H_2O + Cl_2 \longrightarrow Na_2SO_4 + S + 2HCl$ ]

**8.** Fluorine on reaction with  $KIO_3(aq.)$  gives (A) and on reaction with KHSO<sub>4</sub> gives (B). (A) and (B) are:

(a) KIO<sub>4</sub>, K<sub>2</sub>S<sub>2</sub>O<sub>3</sub>

(c) HF,  $K_2S_2O_8$ 

(d)  $I_2, K_2S_2O_8$ 

[Hint:  $KIO_3 + F_2 + H_2O \longrightarrow KIO_4 + H_2F_2$ ;  $2KHSO_4 + F_2 \longrightarrow K_2S_2O_8 + 2HF$ 

9. KClO<sub>3</sub> on reaction with SO<sub>2</sub> gives (A) and on reaction with conc.  $H_2SO_4$  gives (B). (A) and (B) are:

(a) KCl, HClO<sub>4</sub>

(b) Cl<sub>2</sub>, ClO<sub>2</sub>

(c) KCl, HClO<sub>3</sub>

(d) Cl<sub>2</sub>, HClO<sub>4</sub>

[Hint:  $KClO_3 + 3SO_2 + 3H_2O \longrightarrow KCl + 3H_2SO_4$ 

 $3KClO_3 + 3H_2SO_4 \longrightarrow 3KHSO_4 + 3HClO_3$  $2HClO_3 \longrightarrow 2ClO_2 + H_2O + O$ 

 $HClO_3 + O \longrightarrow HClO_4$ 

 $3KClO_3 + 3H_2SO_4 \longrightarrow 3KHSO_4 + 2ClO_2 + HClO_4 + H_2O$ 

10.

$$\operatorname{Br}_2 + \operatorname{OH}^- \longrightarrow (A) + (B)$$

 $(A) + (B) + H^{+} \longrightarrow Br_2$ 

(A) gives yellow precipitate with AgNO<sub>3</sub>. (A) and (B) are:

(a) Br, BrO

(b)  $Br^-$ ,  $BrO_3^-$ 

(c) BrO, BrO3

(d)  $BrO^-$ ,  $BrO_4^-$ 

Hint:

$$3Br_2 + 6OH^- \longrightarrow 5Br^- + BrO_3^- + 3H_2O$$

$$5Br^{-} + BrO_{3}^{-} + 6H^{+} \longrightarrow 3Br_{2} + 3H_{2}O$$

11. 10 g of bleaching powder on reaction with KI required 50 mL of 2N hypo solution. Thus, % of bleaching powder is:

(a) 100

(b) 80

(c) 63.5

(d) 35.5

[Hint: 50 mL 2N hypo soln.  $\equiv$  50 mL 2N I<sub>2</sub> soln.  $\equiv$  50 mL 2N Cl<sub>2</sub> soln.  $\equiv$  50 mL 2N CaOCl<sub>2</sub> soln.

 $\equiv$  6.35 g CaOCl<sub>2</sub>

 $\%\frac{6.35}{10} \times 100 = 63.5$ ]

12.  $HClO_4 + P_2O_5 \longrightarrow (A) + (B)$ 

(A) and (B) are:

(a) HClO<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub>

(b) Cl<sub>2</sub>O<sub>6</sub>, HPO<sub>3</sub>

(c) ClO<sub>2</sub>, H<sub>3</sub>PO<sub>4</sub>

(d) Cl<sub>2</sub>O<sub>7</sub>, HPO<sub>3</sub>

[Hint:  $2HClO_4 + P_2O_5 \longrightarrow Cl_2O_7 + 2HPO_3$ ]

13.  $AgClO_3 + (A) \longrightarrow (B) + (C) + (D)$ 

The substances (A), (B), (C) and (D) are:

(a)  $Cl_2$ , AgCl,  $ClO_2$ ,  $O_2$ 

(b)  $Cl_2$ , Ag,  $Cl_2O_6$ ,  $O_2$ 

(c) H<sub>2</sub>, AgCl, H<sub>2</sub>O, O<sub>2</sub>

(d) HClO, AgCl, Cl<sub>2</sub>O, O<sub>2</sub>

[Hint:  $2AgClO_3 + Cl_2 \longrightarrow 2AgCl + 2ClO_2 + O_2$ ]

14. Select the correct statement(s):

(a) Cl<sub>2</sub>O and ClO<sub>2</sub> are used as bleaching agents and as germicides

(b) ClO<sub>2</sub> is the anhydride of HClO<sub>2</sub> and HClO<sub>3</sub>

(c) I<sub>2</sub>O<sub>5</sub> is used in the quantitative estimation of CO

(d) All of the above are correct

[Hint:  $2ClO_2 + H_2O \longrightarrow HClO_2 + HClO_3$  $I_2O_5 + 5CO \longrightarrow I_2 + 5CO_2$ 

15. Which one of the following represents the reaction between fluorine and cold NaOH (dil.)?

(a)  $2F_2 + 4NaOH \longrightarrow 4NaF + 2H_2O + O_2$ 

(b)  $3F_2 + 6NaOH \longrightarrow 5NaF + NaFO_3 + 3H_2O$ (c)  $F_2 + 2NaOH \longrightarrow NaF + NaOF + H_2O$ 

(d)  $2F_2 + 2NaOH \longrightarrow 2NaF + OF_2 + H_2O$ 

16. Which one of the following pairs of reactants does not form oxygen when they react with each other?

(a) F<sub>2</sub>, NaOH solution (hot, conc.)

(b)  $F_2, H_2O$ 

(c) Cl<sub>2</sub>, NaOH solution (cold, dilute)

(d) CaOCl<sub>2</sub>, H<sub>2</sub>SO<sub>4</sub> (dilute, small amount)

[Hint: (a)  $2F_2 + 4NaOH \longrightarrow 4NaF + 2H_2O + O_2$ (Hot, conc.)

(b)  $2F_2 + 2H_2O \longrightarrow 4HF + O_2$ 

Cl<sub>2</sub> + 2NaOH ---→ NaCl + NaClO + H<sub>2</sub>O (c)

 $2CaOCl_2 + H_2SO_4 \longrightarrow CaCl_2 + CaSO_4 + 2HCl + O_2$ (d)

# **Assertion-Reason Type Questions**

The following questions consist of two statements each, printed as Assertion (A) and Reason (R). While answering these questions, you are required to choose any one of the following responses:

- (a) If both (A) and (R) are true and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are true but (R) is not the correct explanation of (A).
- (c) If (A) is true but (R) is false.
- (d) If (A) is false but (R) is true.
- (e) If both the (A) and (R) are false.
- 1. (A) HClO<sub>4</sub> is a stronger acid than HClO<sub>3</sub>.
  - (R) Oxidation state of chlorine in HClO<sub>4</sub> is +7 and in HClO<sub>3</sub>; it is +5.
- 2. (A) The bond between F-F is stronger than between CI-CI.
  - (R) Atomic size of F is smaller than that of Cl.
- 3. (A) Iodine displaces chlorine from KClO<sub>3</sub>.
  - (R) Iodine is stronger oxidising agent than chlorine.

- 4. (A) All the halogens are coloured.
  - (R) Halogen molecules absorb some wavelengths of visible light and the electrons are promoted to higher energy molecular orbitals.
- 5. (A) Fluorine does not show oxidation number greater than zero.
  - (R) The halogens chlorine, bromine and iodine can show positive oxidation states of +1, +3, +5 and +7.
- 6. (A) The boiling point of HF is maximum among the hydracids of halogens.
  - (R) The high boiling point of HF is due to H-bonding on account of high electronegativity of fluorine.
- 7. (A) Fluorine forms a salt of an oxyacid when treated with NaOH solution.
  - (R) Fluorine can be prepared by passing chlorine through sodium fluoride solution.
- 8. (A) Halogens do not directly combine with oxygen. However, oxides are obtained indirectly.
  - (R) The oxides of fluorine form oxyacids with water.

1. (b)

5. (b)

**6.** (a)

7. (e)

value is due to:

its formation

(d) all of the above

chlorine in the sample is:

[**Hint**: CaOCl<sub>2</sub>·H<sub>2</sub>O  $\longrightarrow$  Cl<sub>2</sub>  ${}^{145}$   ${}^{71}$   ${}^{1}$   ${}^{1}$   ${}^{1}$   ${}^{1}$ 

8. (c)

The percentage of available chlorine in commercial samples

of bleaching powder is usually between 33-38%. The low

(a) incomplete reaction between slaked lime and Cl<sub>2</sub> during

(c) decomposition of bleaching powder when kept in air

3. 3.55 g of bleaching powder when treated with acetic acid and

excess of KI liberated iodine which required 60 mL of 0.5 N

sodium thiosulphate solution. The percentage of available

(b) impurities present in the original slaked lime

## QUESTIONS THOUGH

#### THOUGHT 1

Bleaching powder is a mixed salt of hydrochloric acid and hypochlorous acid. It has the formula, CaOCl<sub>2</sub>·H<sub>2</sub>O. It is manufactured by the action of chlorine on dry slaked lime at 40°C. There is also a view that bleaching powder is a mixture of calcium hypochlorite and basic calcium chloride [Ca(OCl)<sub>2</sub> + CaCl<sub>2</sub>·Ca(OH)<sub>2</sub>·H<sub>2</sub>O].

The amount of chlorine obtained from a sample of bleaching powder by the treatment with excess of dilute acids or CO2 is called available chlorine. A good sample of bleaching powder contains 35-38% of available chlorine. On long standing, it undergoes auto-oxidation and the amount of available chlorine decreases.

The estimation of available chlorine is done volumetrically by (a) iodometric method or by (b) arsenite method.

In textile industry, the cotton cloth is mainly bleached with the help of bleaching powder.

- 1. Maximum percentage of available chlorine on the basis of CaOCl<sub>2</sub>·H<sub>2</sub>O formula is: (a) 35 · · · · · · (b) 40
  - (c) 45

- (d) 49

(a) 30.0

(b) 25.0

(c) 20.0

(d) 35.0

[**Hint**: 60 mL 0.5 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln.  $\equiv$  60 mL 0.5 N I<sub>2</sub> soln.  $\equiv$  60 mL 0.5 N Cl<sub>2</sub> soln.

% available 
$$Cl_2 = \frac{60 \times 0.5 \times 35.5}{1000 \times 3.55} \times 100 = 30$$
 ]

- **4.** On long standing, the bleaching powder undergoes auto-oxidation. The products formed are :
  - (a) calcium chloride only
  - (b) calcium chlorate only
  - (c) calcium chloride and calcium chlorate
  - (d) calcium chloride and calcium chlorite

[Hint:  $6CaOCl_2 \longrightarrow 5CaCl_2 + Ca(ClO_3)_2$ ]

- 5. The chemical name of bleaching powder is:
  - (a) calcium hypochlorite
  - (b) calcium chlorohypochlorite
  - (c) calcium chlorate
  - (d) calcium perchlorate

## THOUGHT 2

A salt (A) when heated with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and conc. H<sub>2</sub>SO<sub>4</sub> liberates a gas which is absorbed in NaOH solution. The NaOH solution turns yellow. When this solution is acidified with acetic acid and lead acetate solution is added, a yellow precipitate (B) is formed,

(A) is mixed with  $MnO_2$  and heated with conc.  $H_2SO_4$  when a gas (C) is evolved which turns starch-iodide paper blue.

- 1. The acidic radical present in the salt (A) is:
  - (a)  $NO_3$

(b) Cl

(c)  $S^{2-}$ 

- (d) I
- The compound formed, which turns NaOH solution yellow, is:
  - (a) Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>
- (b) Na<sub>2</sub>S

(c) NaI

- (d) Na<sub>2</sub>CrO<sub>4</sub>
- 3. What is the colour of gas which is evolved when salt (A) is heated with  $MnO_2$  and  $H_2SO_4$ ?
  - (a) violet
- (b) brown
- (c) greenish yellow
- (d) colourless

# THOUGHT 3

Halogens react with each other to form a number of compounds called interhalogen compounds. Their general formula is  $AX_n$ ; where A is less electronegative halogen while X is a more electronegative halogen and n is its number. The interhalogen compounds are essentially covalent and more reactive than the halogens since the bond A—X is weaker than A—A or X—X bond. The reactions of interhalogens are similar to those of halogens.

1. Which of the following interhalogen compounds is not possible?

(a) IF<sub>7</sub>

(b) IF<sub>5</sub>

(c) CIF<sub>3</sub>

- (d) FCl<sub>3</sub>
- 2. Which halogen shows maximum oxidation state in forming interhalogen compound ?
  - (a) I

(b) Br

(c) C1

- (d) F
- 3. How many lone pairs of electrons are present on chlorine in ClF<sub>3</sub> molecule?
  - (a) 0

(b) 1

(c) 2

- (d) 3
- 4. Which of the following statements is wrong for interhalogen?
  - (a) The value of n in  $AX_n$  (interhalogen) can be 1, 3, 5 or 7
  - (b) The value of n in  $AX_n$  (interhalogen) can be 2, 4, or 6
  - (c) A can never be fluorine as it is most electronegative halogen
  - (d) X can never be iodine as it is least electronegative halogen

## THOUGHT 4

Fluorine, the first member of group 17, differs from the other members of the group in many respects due to following reasons:

- (i) Its size is very small
- (ii) It has very high electronegativity
- (iii) It does not have vacant d-orbitals in the valence shell
- (iv) Its dissociation energy in the molecular form  $(X_2)$  is the least
- **1.** Which member of the group 17 does not show positive oxidation state?
  - (a) Iodine
- (b) Bromine
- (c) Chlorine
- (d) Fluorine
- 2. Which has the maximum molar enthalpy of vaporisation?
  - (a) HF

(b) HCl

(c) HBr

- (d) HI
- 3. Which of the following bonds is the strongest?
  - (a) F-F
- (b) Cl—Cl
- (c) Br—Br
- (d) I—I
- 4. Which halogen does not form any oxyacid?
  - (a) Iodine
- (b) Bromine
- (c) Chlorine
- (d) Fluorine
- 5. The most basic among the following is:
  - (a) CI

(b) Br

(c) F

(d) I

## 13.1 POSITION IN THE PERIODIC TABLE

The zero or 18th group consists of seven elements; helium, neon, argon, krypton, xenon, radon and ununoctium. The zero group was unknown when **Mendeleev** presented the periodic table and has been inserted in the table only at a later stage. The existence of such a group may be naturally expected from the fact that there must be an inert group as transition when we go from highly electronegative elements (halogens) to highly electropositive elements (alkali metals). Thus, zero group occupies the intermediate position between the elements of VIIA (17th) and IA (1st) groups.

The members of zero group are the **end members** of respective periods of the periodic table. Helium is the end member of first period, neon the end member of second period, argon the end member of third period and so on. This is the only group of the periodic table, all members of which are gases and chemically inactive under ordinary conditions. On account of this, these are collectively called as **inactive gases or inert gases**. However, these are now called **noble gases** as some compounds of these gases have been obtained under certain specific conditions, *i.e.*, they do show some chemical activity under special conditions. They are also termed as **zerovalent elements** because they show zero valency due to chemical inertness. On account of zero valency, the group to which these elements belong is termed as zero group.

VIIA (Halogens) Electronegative elements	Zero group	IA (Alkali metals) Electropositive metals		
H (1)	He (2)	Li (3)		
F (9)	Ne (10)	Na (11)		
Cl (17)	Ar (18)	K (19)		
Br (35)	Kr (36)	Rb (37)		
I (53)	Xe (54)	Cs (55)		
At (85)	Rn (86)	Fr (87)		

Except last two members radon and ununoctium which are radioactive, all other members are present in atmosphere in very minute quantities. Thus, these are termed as rare gases of atmosphere.

The chemical inertness of these elements is due to the following reasons:

(i) Stable electronic configuration: All of these, except helium, have the highly stable  $s^2p^6$  configuration in the outer (valency) shell. Helium has the stable  $1s^2$  configuration.

On account of highly stable  $s^2p^6$  configuration in the valency shell, these elements have no tendency either to lose, gain or share electrons with the atoms of other elements, *i.e.*, their combining capacity or valency is zero. These elements are, thus, chemically inert.

- (ii) All the orbitals in the atoms of these elements are doubly occupied, *i.e.*, electrons are not available for sharing. Hence, these elements cannot form covalent compounds.
- (iii) The ionisation enthalpies of these elements are very high. Hence, the atoms of these elements have no tendency to lose electron from the outermost shell as to form cation.
- (iv) The electron gain enthalpy values of these elements are positive. Hence, the atoms of these elements have no tendency to accept electrons, *i.e.*, to form anions.

Element	At. No.	Electronic configuration	Configuration of outer-shell
Не	2	$\frac{1}{s^2}$	1s <sup>2</sup>
Ne	10	$1s^2$ , $2s^22p^6$	$2s^22p^6$
Ar	18	$-2, 8, 8$ $-1s^2, 2s^22p^6, 3s^23p^6$	$3s^23p^6$
Kr	36	2, 8, 18, 8 $1s^2$ , $2s^22p^6$ , $3s^23p^63d^{10}$ , $4s^24p^6$	$4s^24p^6$
Xe	54	2, 8, 18, 18, 8 $1s^2$ , $2s^22p^6$ , $3s^23p^63d^{10}$ , $4s^24p^64d^{10}$ , $5s^25p^6$	$5s^25p^6$
Rn	86	2, 8, 18, 32, 18, 8 $1s^2$ , $2s^22p^6$ , $3s^23p^63d^{10}$ , $4s^24p^64d^{10}4f^{14}$ , $5s^25p^65d^{10}$ , $6s^26p^6$	$6s^26p^6$
Uuo*	118	2, 8, 18, 32, 32, 18, 8 $1s^2$ , $2s^22p^6$ , $3s^23p^63d^{10}$ , $4s^24p^64d^{10}4f^{14}$ , $5s^25p^65d^{10}5f^{14}$ , $6s^26p^66d^{10}$ , $7s^27p^6$	$7s^27p^6$

Besides similar electronic configuration and chemical inertness, the following points justify the inclusion of these elements in the same group of the periodic table. A gradation in the properties is also observed with the increase of atomic number.

- (i) They are all colourless, odourless and tasteless gases.
- (ii) These gases do not burn and also do not help in burning.
- (iii) All are mono-atomic in nature as they have no combining

capacity. The specific heat ratio, *i.e.*,  $\frac{C_p}{C_v}$  for all the inert gases has been found to be 1.66 (theoretical value for mono-atomic character).

Mono-atomic character was also proved by bond order data, bond order of the molecules like He<sub>2</sub>, Ne<sub>2</sub> was calculated to be zero, *e.g.*,

He<sub>2</sub>: Four electron system; its molecular orbital configuration is

Bond order = 
$$\frac{1}{2}$$
 [Number of bonding electrons – Number of antibonding electrons]  
=  $\frac{1}{2}$  [2 - 2] = 0;

zero bond order proves mono-atomic character.

(iv) All have low values of **melting and boiling points.** These values increase gradually as the atomic number increases.

	-	•				
Element	He	Ne	Ar	, Kr	Xe	Rn
Melting point (K)	1	24.6	83.8	115.9	161.3	202
Boiling point (K)	4.2	27.1	87.2	119.7	165	211

Amongst the known elements, helium has got the lowest melting and boiling points. The low melting and boiling points of these gases are due to weak inter-molecular forces of attraction in these cases. The weak intermolecular forces, however, increase with increase of atomic mass from He to Rn and therefore, the melting and boiling points increase gradually.

(v) In a period of representative elements, it is observed that atomic radius decreases as the atomic number increases from 1st group to 17th group. However, the radii values of noble gases which come after the elements of group 17th are exceptionally high. This is due to the fact that in the case of noble gases, the atomic radii correspond to van der Waals' radii which are always larger than covalent radii. van der Waals' radii of noble gases increase gradually from He to Rn. This is due to addition of new energy shell from member to member.

(vi) All have high values of ionisation enthalpies. However, these values decrease from He to Rn. However, the ionisation enthalpy of the inert gas is highest amongst the members of the same period.

Element He Ne Ar Kr Xe Rn First ionisation 2372 2080 1520 1351 1170 1037 enthalpy 
$$(kJ \text{ mol}^{-1})$$

<sup>\*</sup>Recently discovered. It is synthetic, radioactive and unstable element. Not much is known about its properties.

- (vii) These gases are sparingly soluble in water (8 to 40 mL per litre at 25°C). The solubility, in general, increases with increasing atomic number.
- (viii) Except helium, these gases can be adsorbed by coconut charcoal at suitable temperatures.
- (ix) These gases give a characteristic spectra by which they can be easily identified.
- (x) These gases have fairly high electrical conductivity. They produce characteristic coloured lights when an electrical discharge is passed through them at low pressure.
- (xi) These gases are relatively difficult to be liquefied as very weak van der Waals' forces of attraction exist in these gases. However, the liquefaction becomes easier from He to Xe as forces increase gradually.

## 13.2 OCCURRENCE

The noble gases (except radon) always occur in the free state. The chief sources are:

1. Air: It is the most important source for the first five gases. They form about 1% by volume of the air. Argon is the principal constituent and others are present in minute quantities. The percentage by volume of various elements is as given:

Helium	$5.24 \times 10^{-4}$	Neon	$1.82 \times 10^{-3}$
Argon	$9.34 \times 10^{-1}$	Krypton	$1.45 \times 10^{-3}$
Xenon	$8.70 \times 10^{-6}$	_	

- **2. Natural gas:** The natural gas found in certain parts of America and Canada contains 2 to 7% helium. At present, most of the helium is obtained from this source.
- **3. Spring water:** The water of certain springs has been found to contain dissolved helium, argon and neon in very small amounts.
- **4. Radioactive minerals:** Radioactive minerals such as monazite, clevite, pitchblende and uranite contain considerable amounts of helium. The gas is produced as the result of radioactive disintegration of uranium and thorium present in the minerals but instead of escaping, it is retained by minerals probably in a state of solid solution. The gas is obtained when these minerals are either heated at 1000°C in vacuum or heated with sulphuric acid.

# 13.3 HISTORY OF THE DISCOVERY OF NOBLE GASES

The credit for the discovery of inert gases goes to William Ramsay and his co-workers.

## Discovery of argon

In 1785, the English chemist, Henry Cavendish performed an experiment by passing electric discharge through a mixture of purified air (dry) and excess of oxygen. Nitrogen was thus converted into corresponding oxides.

$$N_2 + O_2 \xrightarrow{\text{Electric}} 2NO$$
 $2NO + O_2 \longrightarrow 2NO_2$ 

The oxides of nitrogen and unused oxygen were removed by the use of caustic potash and alkaline pyrogallol solutions, respectively. Cavendish observed that a small volume of the gas which was about 1/120 part of the original air, was left. It was neither nitrogen nor oxygen. Cavendish, however, could not draw any conclusion regarding the nature of the residual gas. This experiment was not given any importance for about 109 years.

In the years 1893-94, Lord Rayleigh while working on accurate determination of densities of gases obtained nitrogen from two sources. The nitrogen obtained from the atmosphere was found to be heavier in comparison to the nitrogen obtained by heating a mixture of ammonium compound (NH<sub>4</sub>Cl) and sodium nitrite. The actual values were found to be 1.2572 g/L for atmospheric nitrogen and 1.2505 g/L for chemical nitrogen. Rayleigh repeated his experiments several times and each time he found the same difference. He, thus, concluded that the nitrogen, obtained from the atmosphere must contain some gas or gases which are heavier than nitrogen.

Rayleigh discussed the problem with Ramsay. Both took up the investigations to prove that a heavier gas was present in atmospheric nitrogen. Two methods were used for the preparation of the new gas:

(i) Ramsay method: This consisted of passing air over hot copper and heated magnesium to remove oxygen and nitrogen, respectively.

$$\begin{array}{c} \text{Air} \longrightarrow \text{heated copper} \longrightarrow \text{heated magnesium} \longrightarrow \text{residue} \\ 2\text{Cu} + \text{O}_2 \longrightarrow 2\text{CuO} \ ; \qquad 3\text{Mg} + \text{N}_2 \longrightarrow \text{Mg}_3\text{N}_2 \end{array}$$

The vapour density of the residue was determined and found to be 20.

(ii) Rayleigh method: Cavendish experiment was repeated. A mixture of air and oxygen was taken and an electric discharge of 6000-8000 volts was passed. After the removal of oxides of nitrogen and unreacted oxygen, the vapour density of the residual gas was determined and it also came to 20.

$$\begin{array}{c} N_2 + O_2 \longrightarrow 2NO \\ 2NO + O_2 \longrightarrow 2NO_2 \\ 2NO_2 + 2NaOH \longrightarrow NaNO_2 + NaNO_3 + H_2O \end{array}$$

Oxygen + Alk. pyrogallol ----- Oxygen absorbed

The gas was examined spectroscopically and the spectrum proved that this was an unknown gas. The gas was found to be chemically inert. The new gas was named argon (Greek: argos, lazy or inert). Later on, it was found that it was not a single gas but a mixture of many gases.

#### Discovery of Helium

On August 18, 1868, there occurred a total solar eclipse in

India. The sun's chromosphere was studied for the first time spectroscopically. **J.C. Jannsen** observed a new bright line in the yellow region of the sun's spectrum which did not coincide with the two known lines  $D_1$  and  $D_2$  due to sodium. He named the new line  $D_3$ . **Frankland and Lockyer** pointed out that new  $D_3$  line was due to a new element which did not occur on earth but only existed in the sun's chromosphere. They, therefore, named it **Helium** (Greek; *helios* means sun).

**Hillebrand,** in 1888, observed that a uranium mineral, clevite, on treatment with dilute sulphuric acid gave out a gas which he thought to be nitrogen as it was chemically inert. **Ramsay** repeated this experiment and examined the evolved gas spectroscopically. The spectrum of the gas was taken and it was analysed by **Crookes.** He confirmed that the spectrum besides other lines contained  $D_3$  line in the yellow region which was similar to  $D_3$  line observed in the sun's spectrum. Ramsay was, thus, first to find helium on the earth. Its vapour density was determined and it was found to be 2. It was also completely chemically inactive like argon.

#### Discovery of other inert gases

A new group, i.e., zero group was introduced in the periodic table to accommodate argon and helium. Argon was placed before potassium and helium was given position before lithium. Ramsay and Travers, thus, predicted that there must be an element before sodium also as to fill the position between helium and argon in the zero group. They further said that atmosphere might be the place where the new element could be searched.

Ramsay and Travers isolated about 16 litres of argon from atmosphere which now they began to suspect to be a mixture of a number of gases and they liquefied it. The liquid was then subjected to careful fractional evaporation under different reduced pressures. Each fraction was examined spectroscopically. From the first fraction, they isolated a new element which gave a number of red lines in the spectrum. It was named neon (meaning new). From the final fraction they isolated two new elements krypton (meaning hidden one) and xenon (meaning stranger) which gave new spectral lines in the spectrum.

The sixth member of the family, radon, was discovered in 1902 amongst the radioactive disintegration products of radium and other isotopes found in thorium and actinium radioactive series.

$$^{226}_{88}$$
Ra  $\xrightarrow{-\alpha}$   $^{222}_{86}$ Rn (Uranium series)  
 $^{224}_{88}$ Ra  $\xrightarrow{-\alpha}$   $^{220}_{86}$ Rn (Thorium series)  
 $^{223}_{88}$ Ra  $\xrightarrow{-\alpha}$   $^{219}_{86}$ Rn (Actinium series)

[The isotope  $^{220}_{86}$ Rn is also called thoron and the isotope  $^{219}_{86}$ Rn, actinon.] This discovery was announced by Dorn but Ramsay had also made similar observations simultaneously.

The last member of the family, ununoctium (118) has been recently discovered. Only three atoms of the new element with an average lifetime of 0.9 milliseconds have been produced so far. Scientists bombarded californium with calcium ions beam for many months.

## 13.4

# ISOLATION OF NOBLE GASES FROM THE ATMOSPHERE

Two methods are used for the separation of noble gases from the atmosphere. These are:

- (i) Chemico-physical method
- (ii) Physical method.

#### (i) Chemico-physical method

This involves the use of some chemical reagents for the removal of nitrogen and oxygen of the air and a physical method for the separation of individual noble gases from the gaseous mixture of five noble gases He, Ne, Ar, Kr and Xe. There are three chemical methods for the isolation of a mixture of all the noble gases from the atmospheric air. These methods are:

- (a) Ramsay and Rayleigh's first method.
- (b) Ramsay and Rayleigh's second method.
- (c) Modern method—Fisher and Ringe's method.

The first two methods are of historical importance only and are not used these days (already dealt in the discovery of argon).

#### Fisher and Ringe's method

This is the modern method for the large scale production of noble gases. Air free from moisture is circulated through an iron retort containing 90 parts of calcium carbide (CaC<sub>2</sub>) and 10 parts of anhydrous calcium chloride (CaCl<sub>2</sub>) kept at 800°C. Both oxygen and nitrogen are removed according to the following equations.

$$\begin{array}{c} \text{CaC}_2 + \text{N}_2 \longrightarrow & \text{CaCN}_2 + \text{C} \\ & \text{Calcium cyanamide} \end{array}$$
 
$$\begin{array}{c} 2\text{C} + \text{O}_2 \longrightarrow 2\text{CO} \\ 2\text{CO} + \text{O}_2 \longrightarrow 2\text{CO}_2 \\ \text{C} + \text{O}_2 \longrightarrow \text{CO}_2 \end{array}$$

Some of the CO<sub>2</sub> combines with calcium carbide.

$$2CaC_2 + 3CO_2 \longrightarrow 2CaCO_3 + 5C$$

The mixture of gases containing CO,  $CO_2$  and noble gases is passed over heated cupric oxide (CuO) when CO is oxidised to  $CO_2$ . The  $CO_2$  is absorbed by caustic potash solution when the gaseous mixture is passed through it.

$$CO + CuO \longrightarrow CO_2 + Cu$$
  
 $2KOH + CO_2 \longrightarrow K_2CO_3 + H_2O$ 

The gaseous mixture which now contains only noble gases is dried by bubbling through conc.  $H_2SO_4$  and is finally passed through tubes packed with phosphorus pentoxide and collected. The purpose of addition of  $CaCl_2$  is to reduce the reaction temperature from  $1000^{\circ}C$  to  $800^{\circ}C$ .

## 13.5 SEPARATION OF NOBLE GASES

#### Dewar's charcoal adsorption method

This method is based on the fact that activated coconut charcoal adsorbs different gases at different temperatures. The mixture of noble gases obtained from atmosphere is taken in a bulb filled with activated coconut charcoal and placed in a cold bath. The gases are allowed to remain in the bulb for about half an hour and unadsorbed gases are removed by a Toepler's pump and kept separately.

At -100°C, coconut charcoal adsorbs argon, krypton and xenon while helium and neon remain free. The unadsorbed helium and neon are brought in contact with another charcoal maintained at -180°C, when neon is adsorbed and helium is obtained in free state. Neon can be recovered from this charcoal on warming.

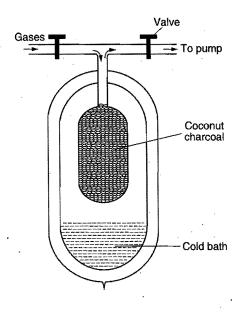

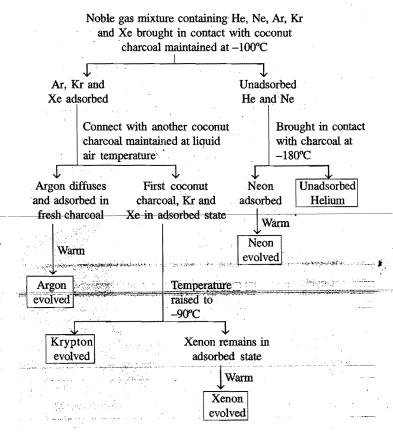

Fig. 13.1

When the charcoal containing Ar, Kr and Xe at -100°C is connected with another charcoal maintained at liquid air temperature, the argon diffuses into this charcoal from which it may be obtained by warming. After the separation of argon, the temperature of first charcoal is raised to -90°C when pure krypton is evolved. Xenon which remains behind is recovered by further warming the charcoal.

The whole process of separation can be summarised with the help of the flow sheet chart given ahead:

#### Physical method (Fractional distillation of liquid air):

Various constituents of liquid air possess different boiling points. These boiling points are:

Helium Neon Nitrogen Argon Oxygen Krypton Xenon -269°C -246°C -196°C -186°C -183°C -152°C -107°C

The sufficient difference in the boiling points of various constituents helps in carrying the fractional distillation of liquid air. This is done in **Claude's apparatus** (Fig. 13.2), which is especially used for the manufacture of liquid oxygen and liquid nitrogen but noble gases are also obtained as by-products.

Cold, compressed air enters the plant at the bottom. It ascends through the rectifier and through the tubes surrounded by liquid oxygen. It gets partially condensed into liquid which collects at the bottom.

The more volatile gases, mainly nitrogen get condensed in the receivers at the side.

The liquid collected at the bottom is pumped up and opens at the middle of the top rectifier. As it flows down, it meets the ascending gases from liquid oxygen. The contact between the two currents makes the descending liquid richer in oxygen which collects at the middle.

Liquid from the side tubes is pumped up to the top. Liquid is partially used for cooling purpose and partially for separation of helium and neon from nitrogen. At the various openings as shown in Fig. 13.2 (ahead), three fractions are obtained.

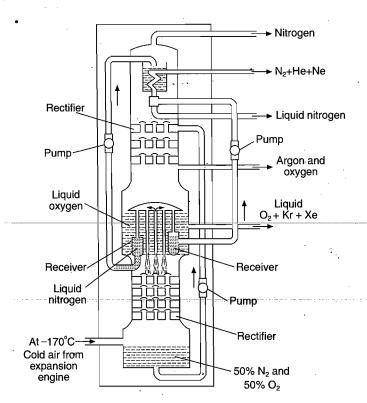

Fig. 13.2 Separation of the noble gases by fractionation

- 1. Helium and neon mixed with gaseous nitrogen.
- 2. Argon and oxygen in gaseous state above liquid oxygen.
- 3. Krypton and xenon present in liquid oxygen. The various noble gases are isolated from these fractions.
- (i) The gaseous mixture of He, Ne and nitrogen is passed through a spiral cooled by liquid nitrogen. Most of the nitrogen present in the gaseous mixture condenses. Nitrogen is completely removed by passing over CaC<sub>2</sub> at 1000°C. Helium and neon are separated by passing the mixture through a spiral cooled by liquid hydrogen (-253°C) when the neon is condensed leaving behind helium in free state.
- (ii) The second fraction containing argon and oxygen is fractionated by passing it around coils containing liquid nitrogen when oxygen is condensed and argon obtained in gaseous state.
- (iii) The liquid containing oxygen, krypton and xenon is fractionally distilled as there is wide difference in their boiling points.

## 13.6 USES OF NOBLE GASES

#### **Helium**

- (i) Since helium is light, non-inflammable, it is used in filling air-ships and balloons for weather study.
- (ii) Unlike nitrogen, helium is not soluble in blood even under high pressure, a mixture of 80% helium and 20% oxygen is used instead of ordinary air, by divers for respiration. The same mixture is used to assist breathing in asthama and other

respiratory diseases. If nitrogen is used along with oxygen in the cylinders of sea divers then nitrogen dissolves in blood at high pressure and create painful sensation called BENDS.

- (iii) Helium is used in research work for maintaining very low temperatures.
  - (iv) It is used in producing inert atmosphere.
  - (v) It is filled in tubes of aeroplane tyres.
  - (vi) It is used for food preservation.
- (vii) Nucleus of helium ( $\alpha$ -particles) are used as bombarding particles in artificial radioactivity.  $\alpha$ -particles are produced from helium using cyclotron.
  - (viii) It is used as filler in electric transformer.

#### Argon

- (i) It is widely used for filling incandescent metal filament electric bulbs.
- (ii) It is also used for filling radio-valves, rectifiers and fluorescent tubes. The neon-argon mixtures are used in advertising signs for various colours.
- (iii) It is used in producing inert atmosphere during welding and extraction of various metals.

Fig. 13.3 Noble gases in cathode ray discharge tubes characteristic glows. Argon glows blue.

#### Meon Neon

(i) It is used in neon discharge lamps and signs which are used for advertising purposes, since the neon lights (generally orange red) are visible from long distances and even visible

Fig. 13.4 Noble gases in cathode ray discharge tubes characteristic glows. Neon glows red.

through fog and mist. If mercury vapours are mixed with neon, a glow of blue or green colour is obtained. Neon lamps

are used over telephone tower, helipad and in music beat indicators of deck.

(ii) It is used in safety devices for protecting electrical instruments as it has a property of carrying exceedingly high currents under high voltages.

#### Krypton and xenon

These are used in filling incandescent metal filament electric bulbs. These gases are considered superior than argon for this purpose.

Krypton-85 is used to determine  $\sigma$  thickness of metal sheet and plastic sheets. Kr-85 is also used in regulating the voltage in electronic tubes.

#### Radon

- (i) It is used in radiotherapy of cancer.
- (ii) It is used to check the defects in steel castings.
- (iii) Photography of internal opaque materials is made with the help of radon.

### 13.7 COMPOUNDS OF NOBLE GASES

On account of stable electronic configuration, high ionisation potential and positive electron affinity, the noble gases are not expected to form chemical compounds with other elements. However, the recent researches have shown that under certain conditions these gases especially the higher ones are capable to form a few compounds. The only compounds known before 1962 were those observed in the discharge tubes or the hydrates and clathrates.

First theoretical support about compounds of inert gases was given by **Van Anthropove** in 1957 by taking into consideration of following compounds:

Molecule	Number of valence $e^-$ with central atom
PCl <sub>5</sub>	10e
SF <sub>6</sub>	12 <i>e</i>
$\mathbf{IF}_7$	14 <i>e</i> .

Central atom of above compounds have more than 8 electrons in valence shell (expanded octet). Thus, zero group elements can also form compounds by expanding their already existing octet.

- (i) Compounds formed in the discharge tubes: Boomer in 1925, reported the formation of WHe<sub>2</sub> by subjecting helium to electron bombardment using tungsten filament. In 1927, Manley reported that in presence of electric discharges mercury and helium combined to form combinations like HgHe<sub>2</sub> or HgHe<sub>10</sub>. Recent researches have shown that these reported compounds are not true chemical compounds.
- (ii) **Hydrates:** The hydrates of argon, krypton and xenon have been reported in literature. These are Ar-6H<sub>2</sub>O, Kr-6H<sub>2</sub>O, Xe-6H<sub>2</sub>O. The formation is due to dipole-dipole interaction. A

strong dipole water when brought in contact with a noble gas under high pressure and low temperature is likely to cause polarisation of the gas atom, *i.e.*, making it as a dipole which attracts the original dipole water.

Recent work of **Wiberg** and **Karbe** has rejected the idea of the formation of such hydrates.

(iii) Clathrates: Noble gases form a number of combinations in which gases are trapped into the cavities of crystal lattices of certain organic and inorganic compounds. These combinations are called **enclosure** or **cage** or **clathrate compounds**. (Latin: *clathrate* = enclosed or protected by cross-bars). The clathrates are normally non-stoichiometric compounds.

When quinol (o-dihydroxy benzene) is allowed to crystallise its solution in water in the presence of heavier noble gases such as argon, krypton or xenon under a pressure of 10-40 atmosphere, the noble gases get trapped within the lattice of quinol crystals. These crystals are quite stable. However, when heated or dissolved in solvent, the gas escapes.

The crystal structure with cavities is called the 'host' and the atom or molecule entrapped in it is called the 'guest'. The formation of a clathrate is only possible when the size of the cavity is such that it can fit in tightly the guest atom or molecule. Thus, helium and neon do not form clathrate compounds with quinol as the size of the cavity is more than the size of helium or neon atom.

(iv) Compounds discovered from 1962 onwards: Bartlett, in 1962, prepared a compound by reacting oxygen with a powerful oxidising agent platinum hexafluoride. The X-ray examination of the solid compound,  $O_2PtF_6$ , showed that it consisted of  $O_2^+$  and  $PtF_6^-$  ions. Bartlett thought that a similar compound could also be prepared with xenon since the ionisation potential of xenon is quite close to the ionisation potential of oxygen. When he reacted xenon with platinum hexafluoride, a red solid compound of composition,  $XePtF_6$  was obtained. Similarly,  $XeRuF_6$ ,  $XeRhF_4$  were also synthesized.

XePtF<sub>6</sub> was first real compound of any of the noble gases. The excitement caused by this discovery led to active search for other noble gas compounds and in a short time three fluorides of xenon, XeF<sub>2</sub>, XeF<sub>4</sub> and XeF<sub>6</sub> had been obtained as white crystalline solids.

**Xenon difluoride,** XeF<sub>2</sub>, is formed by heating a mixture of xenon and fluorine in molecular ratio 1 : 2 at 400°C in a nickel tube.

$$Xe + F_2 \xrightarrow{400^{\circ}C} XeF_2$$

Dioxygen fluoride reacts with Xe at about 118°C to give XeF<sub>2</sub>.

$$Xe + O_2F_2 \xrightarrow{118^{\circ}C} XeF_2 + O_2 \uparrow$$

In presence of mercury arc light, Xe and fluorine combine.

$$Xe + F_2 \xrightarrow{Mercury} XeF_2$$

It is a colourless, crystalline solid (m. pt. 140°C). It is decomposed by hydrogen and water.

$$XeF_2 + H_2 \longrightarrow Xe + H_2F_2$$
  
 $2XeF_2 + 2H_2O \longrightarrow 2Xe + 2H_2F_2 + O_2$ 

It acts as a strong oxidising agent.

$$XeF_2 + I_2 \xrightarrow{BF_3} 2IF + Xe$$
  
 $XeF_2 + 2HCl \longrightarrow Xe + H_2F_2 + Cl_2$ 

XeF<sub>2</sub> dissolves in HF but do not react with HF.XeF<sub>2</sub> forms addition compound with Lewis acids by itself acting as Lewis base, e.g.,

Lewis base + Lewis acid 
$$\longrightarrow$$
 Adduct
$$XeF_2 + 2SbF_5 \longrightarrow XeF_2 \cdot 2SbF_5$$
or
$$[XeF]^+ [Sb_2F_{11}]^-$$

$$XeF_2 + IF_5 \longrightarrow [XeF]^+ [IF_6]^-$$

 $XeF_2$  undergoes hydrolysis in aqueous alkaline solution, e.g.,

$$2XeF_2 + 4OH^- \longrightarrow 2Xe + 4F^- + 2H_2O + O_2$$

Lastly, XeF<sub>2</sub> acts as fluorinating agent also.

$$+ XeF_2 \longrightarrow \bigcirc^F + HF + Xe$$

$$2NO + XeF_2 \longrightarrow 2NOF + Xe$$

$$2NO_2 + XeF_2 \longrightarrow Xe + 2NO_2F$$

Note: Vessels of monel metal (alloy of nickel) are used to store XeF<sub>2</sub>.

**Xenon tetrafluoride,** XeF<sub>4</sub>, is formed by heating a mixture of xenon and fluorine in the molecular ratio 1: 10 at 400°C in a nickel tube.

$$Xe + 2F_2 \xrightarrow{400^{\circ}C} XeF_4$$

It is never synthesized in pure form because its formation is accompanied with the formation of XeF<sub>2</sub> and XeF<sub>6</sub>.

It is a colourless, crystalline solid (m. pt. 107°C). It undergoes sublimation. It is reduced by hydrogen, mercury and boron trichloride.

$$XeF_4 + 2H_2 \longrightarrow Xe + 2H_2F_2$$
  
 $XeF_4 + 2Hg \longrightarrow Xe + 2HgF_2$   
 $3XeF_4 + 4BCl_3 \longrightarrow 4BF_3 + 3Xe + 6Cl_2$ 

It forms a highly explosive solid, xenon trioxide (XeO<sub>3</sub>) when treated with water.

$$2XeF_4 + 3H_2O \longrightarrow Xe + XeO_3 + 3H_2F_2 + F_2$$

It is soluble in fluoroacetic acid ( $CF_3COOH$ ). When it is heated with excess of Xe it changes to  $XeF_2$ .

$$XeF_4 + Xe(excess) \xrightarrow{Warm} 2XeF_2$$

It undergoes addition reactions like XeF<sub>2</sub>, forming adducts.

Other Lewis acids like PF<sub>5</sub>, AsF<sub>5</sub>, SbF<sub>5</sub>, NbF<sub>5</sub>, RuF<sub>5</sub>, OsF<sub>5</sub> also undergo similar addition reactions.

Like  $XeF_2$ , xenon tetrafluoride also acts as fluorinating agent, e.g.,

$$XeF_4 + Pt \longrightarrow Xe + PtF_4$$
  
 $4NO + XeF_4 \longrightarrow Xe + 4NOF$   
 $4NO_2 + XeF_4 \longrightarrow Xe + 4NO_2F$ 

**Xenon hexafluoride,** XeF<sub>6</sub>, is formed by heating xenon and fluorine in molecular ratio 1: 20 under pressure in a nickel tube.

$$Xe + 3F_2 \xrightarrow{300^{\circ}C} XeF_6$$

It is a colourless crystalline solid (m. pt. 49.5°C). It is reduced by H<sub>2</sub>, HCl and NH<sub>3</sub>.

$$XeF_6 + 3H_2 \longrightarrow Xe + 3H_2F_2$$
  
 $XeF_6 + 6HCl \longrightarrow Xe + 3H_2F_2 + 3Cl_2$   
 $XeF_6 + 8NH_3 \longrightarrow Xe + 6NH_4F + N_2$ 

The hydrolysis of XeF<sub>6</sub> with water yields new compounds.

$$XeF_6 + H_2O \longrightarrow XeOF_4 + H_2F_2$$
  
 $XeOF_4 + H_2O \longrightarrow XeO_2F_2 + H_2F_2$   
 $XeO_2F_2 + H_2O \longrightarrow XeO_3 + H_2F_2$ 

Like other xenon fluorides, XeF<sub>6</sub> is also stored in nickel alloy (monel metal) vessel. It cannot be stored in glass vessel because silica in glass reacts with XeF<sub>6</sub>.

$$2XeF_6 + SiO_2 \longrightarrow 2XeOF_4 + SiF_4$$
  
 $2XeOF_4 + SiO_2 \longrightarrow 2XeO_2F_2 + SiF_4$   
 $2XeOF_4 + 2SiO_2 \longrightarrow 2XeO_3 + 2SiF_4$ 

XeF<sub>6</sub> dissolves in HF according to the following reaction

$$XeF_6 + HF \longrightarrow [XeF_5]^+ [HF_2]^-$$

XeF<sub>6</sub> undergoes thermal decomposition

$$2XeF_6 \longrightarrow XeF_2 + XeF_4 + 3F_2$$

Like XeF<sub>2</sub> and XeF<sub>4</sub>, XeF<sub>6</sub> also acts as fluorinating agent. XeF<sub>6</sub> has strongest fluorinating tendency. XeF<sub>6</sub> undergoes addition reactions with Lewis acids, *e.g.*,

$$XeF_6 + AsF_5 \longrightarrow [XeF_5]^+ [AsF_6]^-$$
  
 $XeF_6 + BF_3 \longrightarrow [XeF_5]^+ [BF_4]^-$   
 $XeF_6 + NaF \longrightarrow NaXeF_7$   
 $2NOF + XeF_6 \longrightarrow [NO]_2^{2+} [XeF_8]^{2-}$ 

Hexafluoride undergoes hydrolysis in strongly alkaline medium.

$$2XeF_6 + 16OH^- \longrightarrow 8H_2O + 12F^- + XeO_6^{4-} + Xe + O_2$$

#### Structure of Xenon Fluorides

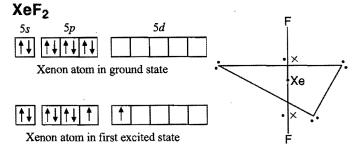

The bonding in these compounds is covalent. The formation involves the unpairing of *p*-orbitals and promotion of electron or electrons to the vacant *d*-orbitals in the outermost shell. In

the excited state, the xenon atom undergoes hybridization forming definite configurations. The unpaired electrons in the hybrid orbitals form covalent (sigma) bonds with fluorine atoms.

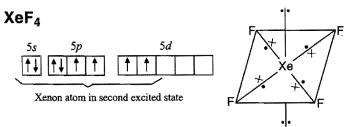

The hybridization of xenon atom and shapes of different fluorides can be predicted with the help of following generalisation:

Hybridization = 1/2 [No. of electrons in the valence shell of central atom + No. of monovalent atoms surrounding the central atom—charge on the cation + charge on the anion]

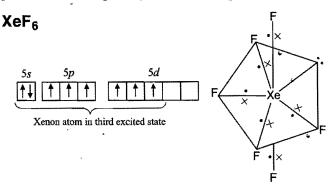

Molecule	Total numb	er of orbitals	Hybridi-	Shape
·	undergoing	hybridization	zation	
XeF <sub>2</sub>	1/2[8 + 2	-0+0]=5		Linear .
XeF <sub>4</sub>	1/2[8+4]	-0+0]=6	$sp^3d^2$	Square planar
XeF <sub>6</sub>		-0+0]=7	$sp^3d^3$	Distorted octahedral

In the formation of  $XeF_2$ ,  $sp^3d$  hybridization occurs which gives the molecule a trigonal bipyramidal structure. The xenon and two fluorine atoms lie in a straight line while the three equatorial positions are occupied by the three lone pairs of electrons.

In the formation of  $XeF_4$ ,  $sp^3d^2$  hybridization occurs which gives the molecule an octahedral structure. The xenon and four fluorine atoms are co-planar while the two equatorial positions are occupied by the two lone pairs of electrons.

In the formation of  $XeF_6$ ,  $sp^3d^3$  hybridization occurs which gives the molecule a pentagonal bipyramidal structure. Six positions are occupied by fluorine atoms and one position is occupied by a lone pair of electrons.

Due to presence of lone pair, distortion in structure takes place. The actual structure is distorted octahedral.

#### HYBRIDIZATION AND SHAPES OF XENON FLUORIDES

Molecule	pairs of	No. of lone pairs of electrons	Total electron pairs	Hybridi- zation	Structure	Actual shape
XeF <sub>2</sub>	2	3	5	sp <sup>3</sup> d	Trigonal bipyramidal	Linear
XeF <sub>4</sub>	4	2	6	$sp^3d^2$	Octahedral	Square planar
XeF <sub>6</sub>	6	1	. 7	$sp^3d^3$	Pentagonal bipyramidal	Distorted

Krypton also forms krypton difluoride (KrF<sub>2</sub>) and krypton tetrafluoride (KrF<sub>4</sub>) under suitable conditions, RnF<sub>2</sub> has also been prepared. However, all attempts have failed to prepare similar compounds in the case of He, Ne and Ar.

Xenon oxides and xenon oxyfluorides: Xenon forms two oxides, xenon trioxide (XeO<sub>3</sub>) and xenon tetroxide (XeO<sub>4</sub>).

Xenon trioxide is obtained by hydrolysis of  $XeF_4$  and  $XeF_6$  with water.

$$6XeF_4 + 12H_2O \longrightarrow 4Xe + 2XeO_3 + 12H_2F_2 + 3O_2$$
$$XeF_6 + 3H_2O \longrightarrow XeO_3 + 3H_2F_2$$

Xenon tetroxide is obtained by the action of anhydrous sulphuric acid on barium perxenate.

$$Ba_2 [XeO_6] + 2H_2SO_4 \longrightarrow 2BaSO_4 + XeO_4 + 2H_2O$$

XeO<sub>3</sub> is a colourless explosive solid. It is a powerful oxidising agent. It oxidises Pu<sup>2+</sup> to Pu<sup>4+</sup> in the presence of H<sup>+</sup> ions.

$$3Pu^{2+} + XeO_3 + 6H^+ \longrightarrow 3Pu^{4+} + Xe + 3H_2O$$

 $XeO_3$  reacts with aqueous alkali to form the hydrogen xenate ion (HXeO $_4$ ) which slowly disproportionates to give xenon and perxenate ion (XeO $_6$ ) in which xenon is present in +8 oxidation state.

$$XeO_3 + OH^- \longrightarrow HXeO_4^-$$
  
 $2HXeO_4^- + 2OH^- \longrightarrow XeO_6^{4-} + Xe + 2H_2O + O_2$ 

Perxenate solutions are yellow and powerful oxidising agents.  $XeO_4$  is less stable than  $XeO_3$  and decomposes into xenon and oxygen.

$$XeO_4 \longrightarrow Xe + 2O_2$$

Xenon oxyfluorides: A number of oxyfluorides are known.

- (i) Xenon oxydifluoride (XeOF<sub>2</sub>)
- (ii) Xenon dioxydifluoride (XeO<sub>2</sub>F<sub>2</sub>)
- (iii) Xenon oxytetrafluoride (XeOF<sub>4</sub>)
- (iv) Xenon dioxytetrafluoride (XeO<sub>2</sub>F<sub>4</sub>)
- (v) Xenon trioxydifluoride (XeO<sub>3</sub>F<sub>2</sub>).

Some of the oxyfluorides are obtained by partial hydrolysis of  $XeF_4$  and  $XeF_6$ .

$$XeF_4 + H_2O \longrightarrow XeOF_2 + H_2F_2$$
  
 $XeF_6 + H_2O \longrightarrow XeOF_4 + H_2F_2$   
 $XeOF_4 + H_2O \longrightarrow XeO_2F_2 + H_2F_2$ 

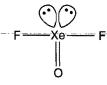

Shapes of xenon oxides and xenon oxyfluorides: The shapes of oxygen containing compounds of xenon are correctly predicted on the basis of Valence Bond Theory and Valence Shell Electron Pair Repulsion Theory.

In this case  $\pi$ -electrons must be subtracted in counting the total number of electron pairs in the valence shell of central atom.

# 13.8 IMPORTANCE OF NOBLE GASES IN THEORETICAL CHEMISTRY

Noble gases have played an important role in the development of various subjects of theoretical chemistry.

- (i) Improvement in periodic table: Insertion of zero group between highly electronegative halogens and highly electropositive alkali metals improved the periodic table. Zero group occupies the intermediate position between two extreme groups of elements.
- (ii) In establishing the scheme for the arrangement of electrons in atoms: All noble gases except helium have 8 electrons in the outermost energy shell. This configuration accounts for the inertness of these elements. It led Bohr and Bury to assume that the outermost energy shell of any stable atom cannot have more than 8 electrons.
- (iii) In the development of electronic theory of valency: All elements tend to acquire stable configuration during chemical union. This is possible when they acquire noble gas configuration, *i.e.*, 8 electrons in the outermost energy shell. This occurs either by transference of electrons from one atom to another (electrovalency) or by sharing of electrons (covalency) or by contributing both electrons to be shared by only one atom (coordinate valency).
- (iv) Group displacement law in radioactivity: α-particles are emitted by the disintegration of radioactive elements. Alphaparticles are actually helium nuclei. It has proved useful in formulating the theory of radioactive disintegration and the group displacement law.
- (v) In the discovery of isotopes: Neon was the first non-radioactive element whose isotopes were first of all separated. On this basis, it was concluded that other elements

may also consist of a mixture of two or more isotopes. This has helped in the discovery of many new isotopes.

#### 13.9 DETERMINATION OF ATOMIC MASS OF A NOBLE GAS

Chemical equivalent masses of noble gases cannot be determined by usual methods as these are chemically inert. Thus, the following relationship cannot be used for the determination of atomic masses of noble gases.

Atomic mass = Equivalent mass  $\times$  valency

The molecular mass of any gaseous element is related with its atomic mass by the following relationship:

Molecular mass = Atomicity  $\times$  Atomic mass

The atomicity of noble gases is unity.

Thus, Molecular mass = Atomic mass

Molecular mass can easily be calculated if vapour density is determined experimentally.

Mol. mass =  $2 \times$  vapour density

At. mass =  $2 \times$  vapour density or

# SUMMARY AND IMPORTANT POINTS TO REMEMBER

- 1. The zero or 18th group consists of seven elements—helium, neon, argon, krypton, xenon, radon and ununoctium. This group was unknown when Mendeleev presented the periodic table and has been inserted only at a later stage. It occupies an intermediate position between electronegative elements of VIIA (17th) and electropositive elements of IA (1st) groups.
- 2. The members of zero group are the end members of respective periods of periodic table. This is the only group of the periodic table, all members of which are gases and chemically inactive under ordinary conditions. These are collectively called as inactive or inert gases. However, these are now called noble gases as some compounds of these gases have been obtained under specific conditions. They are also termed zerovalent elements because they show zero valency.
- 3. Except radon which is radioactive, all other members are present in atmosphere in minute quantities. Thus, they are termed rare gases of atmosphere. They form about 1% by volume of the air. Argon is the priamoal constituent.
- All the noble gases have stable configuration. Except helium which has  $1s^2$  configuration, rest has 8 electrons, i.e.,  $s^2p^6$ configuration in the outer shell. They have no tendency either to lose, gain or share electrons with the atoms of other
- 5. Ionisation potential values are high. However, decreases on moving down the group.
- Electron affinity values are positive.
- 7. They all are colourless, odourless and tasteless gases. All are mono-atomic in nature as  $C_p/C_v$  value for every gas is 1.66. All have low values of melting and boiling points. The values increase as the atomic number increases.

Among the known elements, helium has got the lowest melting and boiling points.

- 8. These gases have fairly high electrical conductivity. They produce characteristic coloured lights when an electrical discharge is passed through at low temperature.
- 9. These gases are relatively difficult to be liquefied. Liquefaction becomes easier from He to Xe.
- 10. These gases are sparingly soluble in water. The solubility increases with increasing atomic number.
- 11. Except He, these gases can be adsorbed by coconut charcoal at suitable temperatures.

- 12. Noble gases always occur in the free state. The chief sources are:
  - (a) Air
  - (b) Natural gas: contains up to 7% helium.
  - (c) Radioactive minerals : only He.

  - (d) Spring water—dissolved He, Ne and Ar. (e) Radon—radioactive decay  $^{226}_{88}$ Ra  $\longrightarrow$   $^{222}_{86}$ Rn +  $^{4}_{2}$ He.
- 13. Argon—Greek word-argos meaning lazy or inert.

Helium—Greek word-helios meaning sun. First reported on the surface of sun.

Neon-Meaning new.

Krypton—Meaning hidden one.

Xenon-Meaning stranger.

The credit for the discovery of above gases goes to Ramsay and Travers. Radon was discovered by Dorn.

- 14. Two methods are used for the separation of noble gases from the atmosphere.
  - (i) Chemico-physical method: It involves the use of some chemical reagents for the removal of nitrogen and oxygen of the air and a physical method for the separation of individual noble gases from the gaseous mixture. The modern method for isolation of gaseous mixture of noble gases from air is:

Fisher-Ringe's method: Air free from moisture and CO<sub>2</sub> is passed over a mixture in an iron retort containing 90% CaC<sub>2</sub> and 10% CaCl<sub>2</sub> anhydrous kept at 800°C. Both O2 and N2 are removed.

$$\begin{array}{ccc}
CaC_2 + N_2 \longrightarrow CaCN_2 + C \\
2C + O_2 \longrightarrow 2CO \\
2CO + O_2 \longrightarrow 2CO_2
\end{array}$$
or  $C + O_2 \longrightarrow CO_2$ 

The mixture of gases containing CO, CO<sub>2</sub> and noble gases is passed over heated CuO when CO is oxidised to CO<sub>2</sub>. The CO<sub>2</sub> is absorbed in caustic potash solution and the unabsorbed gases are dried over P2O5.

Noble gases mixture is separated into individual gases by Dewar's charcoal adsorption method. At -100°C, coconut charcoal adsorbs argon, krypton and xenon. The unadsorbed He and Ne are separated at −180°C, when neon is adsorbed and helium is left free. Neon is recovered by warming the charcoal. When the charcoal containing Ar, Kr and Xe is connected with another charcoal at liquid air temperature, the argon diffuses to new charcoal from which it can be obtained by warming. When the temperature of first charcoal is raised to -90°C, krypton is set free and on further warming, xenon is recovered.

- (ii) Physical method of separation, i.e., distillation of liquid air. For fractional distillation of liquid air claude's apparatus is used. Three fractions are obtained:
  - (a) Helium and neon mixed with gaseous nitrogen.
  - (b) Argon and oxygen in gaseous state.
  - (c) Krypton and xenon present in liquid oxygen.

    These mixtures are further fractionally separated into individual members.
- **15.** (a) Since helium is light and non-inflammable, it is filled in filling airships and balloons.
  - (b) A mixture of 80% helium and 20% oxygen is used instead of ordinary air for respiration by sea divers and asthama patients.
  - (c) Helium is used for inflating the tyres of big aeroplanes in place of air being lighter.
  - (d) Argon is used in creating inert atmosphere during extraction of various metals and welding.
  - (e) Argon is used for filling incandescent metal filament electric bulbs, radio-valves and fluorescent tubes.
  - (f) Liquid helium is used as cryogenic.
  - (g) Neon signs for advertising contain neon gas.
  - (h) Radon is used in radiotherapy of cancer.
- **16.** Until 1962, no real compound of noble gases was known. In 1962, it was observed that oxygen reacts with PtF<sub>6</sub> to form a compound O<sub>2</sub><sup>+</sup>[PtF<sub>6</sub>]<sup>-</sup>.

Since  $O_2$  molecule has ionisation energy  $[O_2 \longrightarrow O_2^+ + e;$  1166 kJmol<sup>-1</sup>] almost same as that of Xe [Xe  $\longrightarrow$  Xe<sup>+</sup> + e; 1170 kJmol<sup>-1</sup>], Neil Bartlett suggested that PtF<sub>6</sub> should show a similar reaction with xenon. He then tried to react these two at 298 K. He actually obtained the compound, XePtF<sub>6</sub>.

XePtF<sub>6</sub> was first real compound of any of the noble gases and in a short time three fluorides of xenon, XeF<sub>2</sub>, XeF<sub>4</sub> and XeF<sub>6</sub> has been obtained as crystalline solids.

$$Xe + F_2 \xrightarrow{\begin{array}{c} 1:2 \text{ 400°C} \\ \text{Ni} \end{array}} XeF_2$$

$$\xrightarrow{\begin{array}{c} 1:10 \text{ 400°C} \\ \text{Ni} \end{array}} XeF_4$$

$$\xrightarrow{\begin{array}{c} 1:20 \text{ 300°C} \\ \text{50 atm.} \end{array}} XeF_6$$

Xenon fluorides react with hydrogen, water and fluoride ion acceptors like, PF<sub>5</sub>, SbF<sub>5</sub> and AsF<sub>5</sub>, etc.

$$XeF_2 + H_2 \longrightarrow Xe + H_2F_2;$$
  
 $2XeF_2 + 2H_2O \longrightarrow 2Xe + 2H_2F_2 + O_2;$   
 $XeF_4 + 2H_2 \longrightarrow Xe + 2H_2F_2;$   
 $2XeF_4 + 3H_2O \longrightarrow Xe + XeO_3 + 3H_2F_2 + F_2;$ 

$$\begin{split} XeF_6 + 3H_2 &\longrightarrow Xe + 3H_2F_2; \\ XeF_6 + H_2O &\longrightarrow XeOF_4 + H_2F_2; \\ XeF_2 + IF_5 &\longrightarrow [XeF]^+ [IF_6]^-; \\ XeOF_4 + H_2O &\longrightarrow XeO_2F_2 + H_2F_2; \\ XeF_4 + SbF_5 &\longrightarrow [XeF_3]^+ [SbF_6]^-; \\ XeO_2F_2 + H_2O &\longrightarrow XeO_3 + H_2F_2; \\ XeF_6 + AsF_5 &\longrightarrow [XeF_5]^+ [AsF_6]^- \end{split}$$

- 17. Xenon forms two oxides xenon trioxide (XeO<sub>3</sub>) and xenon tetroxide (XeO<sub>4</sub>). Xenon trioxide is a colourless explosive solid. It is a powerful oxidising agent. Xenon tetroxide is less stable than XeO<sub>3</sub> and decomposes into Xe and O<sub>2</sub>.
- 18. A number of oxyfluorides of xenon are known:
  - (i) Xenon oxydifluoride, XeOF<sub>2</sub>
  - (ii) Xenon dioxydifluoride, XeO<sub>2</sub>F<sub>2</sub>
  - (iii) Xenon oxytetrafluoride, XeOF<sub>4</sub>
  - (iv) Xenon dioxytetrafluoride, XeO<sub>2</sub>F<sub>4</sub>
  - (v) Xenon trioxydifluoride, XeO<sub>3</sub>F<sub>2</sub>

19.	Molecule	Hybridization of central atom	No. of lone pair(s) around central atom	Shape
	XeF <sub>2</sub>	$sp^3d$	3	Linear,

				and two π bonds

- **20.** No compound of He and Ne is known so far. Helium and neon do not form any clathrate due to small size. Ar, Kr and Xe form clathrates.
- 21. Noble gases have played an important role in the development of various subjects of theoretical chemistry such as:
  - (a) Improvement in periodic table by introducing zero group.
  - (b) In establishing the scheme for the arrangement of electrons in various energy shells of atoms.
  - (c) In the development of electronic theory of valency.
  - (d) Group displacement law in radioactivity.
  - (e) In the discovery of isotopes.

# PRACTICE PROBLEMS

#### Subjective Type Questions

- 1. Name the noble gas which:
  - (i) is abundant in atmosphere
  - (ii) is found in natural gas
  - (iii) is radioactive
  - (iv) is not adsorbed in coconut charcoal
  - (v) highest boiling point.
- (a) Which was the first noble gas compound synthesized? Who prepared it?
  - (b) Which one of the following does not exist?
    - (i)  $XeOF_4$  (ii)  $NeF_2$  (iii)  $XeF_2$  (iv)  $XeF_6$
  - (c) Name the chemical compound which can remove both nitrogen and oxygen from pure and dry air.
- 3. (a) What were the reasons for late discovery of noble gases?
  - (b) What made Rayleigh suspect that there may be an additional element in air?
  - (c) Why noble gas compounds are formed only with O<sub>2</sub> and
- Complete the following reactions:
  - (i)  $XeF_4 + H_2O \longrightarrow$
  - (ii)  $XeF_2 + H_2 \longrightarrow$
  - (iii)  $XeF_6 + SiO_2 \longrightarrow$
  - (iv)  $XeF_6 + NH_3 \longrightarrow$
  - (v)  $XeF_6 + H_2O \longrightarrow$
  - (vi)  $XeF_6 + SbF_5 \longrightarrow$
- Answer the following with relevant reason.
  - (i) Why the group in which inert gases are accommodated was called zero group?

[Hint: Inert gases do not show chemical activity under ordinary conditions due to possession of completed outermost shell, i.e., they show zero valency. On account of zero valency, the group in which inert gases were placed was called zero group.]

(ii) Why the zero group elements do not form compounds under ordinary conditions?

[Hint: Zero group elements have complete electronic configuration of their outermost shells, i.e.,  $s^2p^6$  (except helium which has 1s<sup>2</sup>), hence they do not have any tendency either to lose or accept electron/electrons or share electrons with other atoms.]

(iii) Xenon has closed shell configuration but is known to give compounds with fluorine.

[Hint: Xenon atom has large size and lower ionisation potential in comparison to He, Ne, Ar and Kr. The outermost energy shell has d-orbitals. The paired electrons of valency shell can be unpaired and the electrons are shifted to d-orbitals under suitable conditions. The unpaired electrons are shared by fluorine atoms and covalent bonds are formed. In this way, xenon forms compounds with fluorine.]

- (iv) Helium and neon do not form compounds with fluorine.
  - [Hint: He and Ne are smaller atoms and possess very high ionisation potential. Both do not have d-orbitals in their valency shells. Thus, the paired orbitals of valency shell cannot be unpaired. In absence of singly occupied orbitals, no sharing is possible with other atoms. Hence, no compounds are formed by He and
- (v) The boiling points of noble gases increase with increase in atomic number.

Hint: van der Waals' forces of attraction among molecules increase with the increase of atomic masses. Thus, higher energy is required to separate these molecules as to get gaseous state. Hence, the boiling points increase with increase of atomic masses.]

- (vi) Why neon is used in warning signal illuminations? [Hint: Neon lights are visible from long distances. The lights are even visible during fog and mist conditions.]
- (vii) A mixture of He and O2 is used for respiration by sea divers.

[Hint: Unlike nitrogen, helium is not soluble in blood even under high pressure.]

(viii) Why helium and neon do not form clathrate compounds with quinol?

[Hint: The size of the cavities formed during crystallisation of quinol is more than the size of helium and neon atoms.]

(ix) Why xenon does not form fluorides such as XeF, XeF<sub>3</sub> or XeF<sub>5</sub>?

[Hint: By unpairing of one paired orbital, two singly occupied orbitals come into existence. Thus, either two or four or six singly occupied orbitals can be formed instead of one or three or five singly occupied orbitals. Hence, XeF or XeF<sub>3</sub> or XeF<sub>5</sub> are not formed.]

Draw the molecular structures of XeF<sub>2</sub>, XeF<sub>4</sub> and XeO<sub>2</sub>F<sub>2</sub> indicating the location of lone pair(s) of electrons.

[I,I,T, 2000]

What is the hybridization of xenon in, geometry and shape of the following molecules?

XeOF<sub>2</sub>, XeOF<sub>4</sub>, XeO<sub>2</sub>F<sub>2</sub> and XeF<sub>6</sub>.

|Hint:

:	Molecule	Hybridization of xenon	Geometry	Shape
	XeOF <sub>2</sub>	$sp^3d$	Trigonal bipyramidal	T-shaped
	XeOF <sub>4</sub>	$sp^3d^2$	Octahedral	Square pyramidal
	XeO <sub>2</sub> F <sub>2</sub>	sp <sup>3</sup> d	Trigonal bipyramidal	Distorted trigonal bipyramidal
	XeF <sub>6</sub>	$sp^3d^3$	Pentagonal bipyramidal	Distorted octahedral

**8.** Does the hydrolysis of XeF<sub>6</sub> lead to a redox reaction?

[Hint: When XeF<sub>6</sub> undergoes hydrolysis, it forms XeOF<sub>4</sub>, XeO<sub>2</sub>F<sub>2</sub> and XeO3 as products. In these compounds, there is no change in oxidation state of Xe. Thus, the hydrolysis of XeF<sub>6</sub> is not a redox reaction.]

#### Matching Type Questions

#### Match the following:

- (i) Helium
- (a) Lazy
- (ii) Neon
- (b) Hidden one
- (iii) Argon
- (c) Stranger
- (iv) Krypton
- (d)  $1s^2$ ,  $2s^22p^6$
- (v) Xenon
- (e) Sun's element
- (vi) Radon
- (f) Radioactive

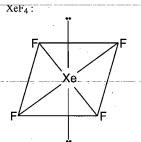

#### Answers: Subjective Type Questions

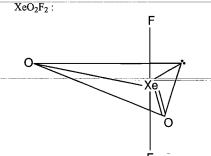

- (i) Argon
- (ii) Helium (iii) Radon or ununoctium
  - (iv) Helium (v) Xenon
- (a) XePtF<sub>6</sub>, Bartlett (b) NeF<sub>2</sub>
- (c) CaC<sub>2</sub> (Calcium Carbide)
- (a) Chemical inertness and rare abundance
  - (b) Density of nitrogen isolated from air was always higher than the nitrogen obtained chemically.
  - (c) Because noble gases have extremely low reactivity, they need strongest oxidising agents to form compounds.
- (i)  $2XeF_4 + 3H_2O \longrightarrow Xe + XeO_3 + 6HF + F_2$  (It undergoes disproportionation.)
  - $XeF_2 + H_2 \longrightarrow Xe + 2HF$
  - $2XeF_6 + SiO_2 \longrightarrow 2XeOF_4 + SiF_4$ 

    - $2XeOF_4 + SiO_2 \longrightarrow 2XeO_2F_2 + SiF_4$   $2XeO_2F_2 + SiO_2 \longrightarrow 2XeO_3 + SiF_4$ Explosive
  - $XeF_6 + 8NH_3 \longrightarrow Xe + 6NH_4F + N_2$
  - $XeF_6 + 3H_2O \longrightarrow XeO_3 + 6HF$ (v)
  - $XeF_6 + SbF_3 \longrightarrow [XeF_5]^+ [SbF_6]^-$

[Addition ionic product is formed.]

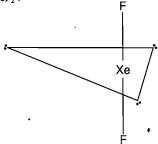

6.

Trigonal bipyramid

 $XeF_2$ :

## **Objective Questions for IIT ASPIRANTS**

- 1. What are the products formed in the reaction of xenon hexafluoride with silica?
  - (a) XeSiO<sub>4</sub> + HF
- (b)  $XeF_2 + SiF_4$
- (c)  $XeOF_4 + SiF_4$
- (d)  $XeO_3 + SiF_4$

[Hint:  $2XeF_6 + SiO_2 \longrightarrow 2XeOF_4 + SiF_4$ ]

- 2. Which of the following two are isostructural?
  - (a) XeF<sub>2</sub>, IF<sub>2</sub>
- (b) NH<sub>3</sub>, BF<sub>3</sub>
- (c)  $CO_3^{2-}$ ,  $SO_3^{2-}$
- (d) PCl<sub>5</sub>, ICl<sub>5</sub>

[Hint: XeF<sub>2</sub> is a linear molecule (Xe is  $sp^3d$  hybridized with three equatorial positions occupied by lone pairs).  $IF_2^-$  is a linear molecule (I is  $sp^3d$  hybridized, with three positions occupied by lone pairs).]

- 3. Number of atoms of He in 100 amu of He (atomic mass of He is 4) are:
  - (a)  $100 \times 6 \times 10^{23}$
- (b) 100

(c) 50

(d) 25

Mass of substance [Hint: No. of atoms = Atomic mass

- 4. The noble gas which shows abnormal behaviour in liquid state and behaves as a superfluid is:
  - (a) neon

- (b) helium
- (c) argon
- (d) xenon
- 5.  $XeF_2$  reacts with  $SbF_5$  to form:
  - (a)  $[XeF][SbF_6]$
- (b)  $[XeF_3][SbF_4]$
- (c) XeSbF<sub>6</sub>
- (d) XeF<sub>4</sub>
- Which of the following compounds is explosive?
  - (a) XeF<sub>2</sub>
- (b) XeF<sub>4</sub>
- (c) XeO<sub>3</sub>
- (d) XeF<sub>3</sub>
- 7. XeF<sub>6</sub> on reaction with CsF gives:
  - (a)  $[XeF_5][CsF_2]$
- (b) XeF<sub>8</sub>
- (c)  $[XeF_4][CsF_3]$
- (d) Cs[XeF<sub>7</sub>]
- **8.** Which of the following is/are solid at room temperature?
  - (a)  $XeF_2$

- (c) XeF<sub>6</sub>
- (b) XeF₄
- (d) All of these

# Matrix Matching Questions for IIT

#### On p-block elements

1. Match the elements of List-I with their uses in List-II:

#### List-I

#### List-II

(Element)

(Uses)

- (b) Rn
- (c) Ne

(d) Ar

- (a) He

- (p) Treatment of cancer
  - (q) Used in caution lamp
  - (r) Filled in the oxygen cylinders of sea divers
  - (s) Filled in electric bulbs
  - (t) Used in airship balloons

2. Match List-II with List-II:

#### List-I

- (a) XeF<sub>2</sub>
- (b) PCl<sub>5</sub>
- (c) XeOF<sub>4</sub> (d) XeF<sub>4</sub>
- 3. Match List-I with List-II: List-I

- (a) He (b) Xe
- (c) XeF<sub>6</sub>
- (d) IF<sub>7</sub>

- List-II
- (p) Square pyramidal
- (q) Linear shape
- (r)  $sp^3d$  hybridization
- (s)  $sp^3d^2$

#### List-II

- (p) London dispersion force
- (q) Lowest boiling noble gas
- (r)  $sp^3d^3$  hybridization
- (s) Distorted octahedral

Match the process in List-I with compounds in List-II and the 8. Match List-II with List-II: catalyst used in List-III: List-I List-II List-I List-II List-III (a) Pnicogens (p) Group-17-elements (a) Haber's process (p) Manufacture of (u) Iron powder (b) Halogens (q) Group-15-elements chlorine (r) Group-16-elements (c) Chalcogens (s) Group with solid, liquid (b) Deacon's process (q) Manufacture of (v) Pt gauge (d) Group with eight atoms nitric acid in the molecular form of and gaseous elements in free (c) Ostwald's process (r) Manufacture of (w) Copper(II) element state vanaspati ghee chloride 9. Match List-II with List-II: (d) Hydrogenation of (s) Manufacture of (x) Finely divided List-II List-I vegetable oils ammonia nickel (a) S-S linkage (p) Dithionic acid Match List-I with List-II: (b) -O-O- linkage (q) Thio-sulphuric acid List-II List-I (c)  $H_2S_2O_8$ (r) Caro's acid \_(Hybrid state-shape) (d) H<sub>2</sub>SO<sub>5</sub> (s) Marshall's acid (Compound) 10. Match List-II with List-II: (a) BCl<sub>3</sub> (p)  $sp^2$ List-I List-II (q)  $sp^3$ (b)  $H_3BO_3$ (a) Be(OH)<sub>2</sub> (p) Oxidising agent (c)  $B_2H_6$ (r) Bridge structure (b) HNO<sub>3</sub> (q) Amphoteric (d) Hybrid state of B and N (s) Triangular planar shape (c) HNO<sub>2</sub> (r) Gelatinous white ppt. in (H<sub>3</sub>NBF<sub>3</sub>) (s) Reducing agent (d)  $Al(OH)_3$ Match the halides of List-I with their properties in List-II: 11. Match each of the reactions given in column-I with corresponding List-I List-II ILLT, 20091 product(s) given in column-II: (a) BeCl<sub>2</sub> (p) Dimeric Column-I Column-II (a) Lewis Acid (b) AlCl<sub>3</sub> (a) Cu + dil. HNO3 (p) NO (r) Tetrahedral (c) CCl<sub>4</sub> (b) Cu + conc. HNO<sub>3</sub> (q) NO<sub>2</sub> (d) SiCl<sub>4</sub> (s) Pyrene (c) Zn + dil. HNO<sub>3</sub> (r)  $N_2O$ (t) Polymeric (d) Zn + conc. HNO<sub>3</sub> (s)  $Cu(NO_3)_2$ 7. Match the elements in List-I with their properties in List-II: (t)  $Zn(NO_3)_2$ List-I List-II (a)  $O_2(g)$ (p) Paramagnetic (b)  $S_2(g)$ (q) Two unpaired electrons (c) Po (r) Radioactive (d) Rn (s) Formed by α-decay of radium

## tuswers

- 1. (a-r, t)(b-p) (c-q) (d-s)7. (a-p, q) (b-p, q) (a-q, r) (b-r)(c-p, s) (d-s)(a-q) (b-p, s)(a-p, q) (b-p) (c-r, s) (d-r)(b-r, s)(a-p, q)(d-r-x)(a-s-u) (b-p-w)(c-q-v)(a-q) (b-p) 11. (a-p, s) (a-p, s) (d-q)(b-p) (c-q, r)(b-q, s)(a-t) (b-p, q) (c-r, s)(d-r)

  - , (c-p, s) (d-q, r)
    - (d-q, t)(c-r, t)

# Assertion-Reason Type Questions

The following questions consist of two statements as Assertion (A) and Reason (R). While answering these questions, you are required to choose any one of the following responses.

- (a) If both (A) and (R) are true and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are true but (R) is not the correct explanation of (A).
- (c) If (A) is true but (R) is false.
- (d) If both (A) and (R) are false.

- 1. (A) Helium and neon do not form clathrates.
  - (R) Both have smallest atomic size among all the elements of group 18.
- 2. (A) The elements of group 18 are called inert gases.
  - (R) The elements of group 18 are mono-atomic in nature.
- 3. (A) Noble gases have highest ionisation energies in their respective periods.
  - (R) The outermost shell of the noble gases is completely filled.

- **4.** (A) Noble gases can combine with fluorine to form respective fluorides under specific conditions.
  - (R) Fluorides of He, Ar and Ne are unstable in nature.
- 5. (A) Noble gases are diamagnetic atoms.

- (R) The atomic numbers of noble gases are even and all the orbitals are doubly occupied by the electrons.
- 6. (A) He<sub>2</sub> does not exist.
  - (R) Bond order of He<sub>2</sub> is zero.

**2.** (b)

**3.** (c)

4. (d)

5. (a)

**6.** (a)

# THOUGHT TYPE QUESTIONS

#### THOUGHT

The noble gases have closed shell electronic configuration and are monoatomic gases under normal conditions. The low boiling points of lighter noble gases are due to weak dispersion forces between the atoms and the absence of other interatomic interactions.

The direct reaction of xenon and fluorine leads to a series of compounds with oxidation numbers +2, +4 and +6. XeF<sub>4</sub> reacts violently with water to give XeO<sub>3</sub>. The compounds of xenon exhibit rich stereochemistry and their geometries can be deduced considering the total number of electron pairs in the valence shell.

[LI.T. 2007]

- 1. Argon is used in arc welding because of its:
  - (a) low reactivity with metal
  - (b) ability to lower the melting point of metal
  - (c) flammability
  - (d) high calorific value
- 2. The structure of XeO<sub>3</sub> is:
  - (a) linear

- (b) planar
- (c) pyramidal
- (d) T-shaped
- 3.  $XeF_4$  and  $XeF_6$  are expected to be:
  - (a) oxidising
- (b) reducing
- (c) unreactive
- (d) strongly basic

Thought 1

1. (a)

2. (c)

3. (a)

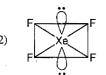

# INTEGER ANSWER THE Constitute

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. How many noble gases are radioactive in nature?
- 2. What is the bond order of Ne<sub>2</sub>?
- 3. What is the percentage by volume of inert gases in the atmosphere?
- **4.** How many lone pairs of electrons are present on xenon atom in  $XeF_4$ ?
- **5.** Xenon hexafluoride reacts with silica. What is the oxidation state of xenon in the xenon compound formed?

## Auswers

- 1. (2) Radon and ununoctium.
- 2. (0) Number of bonding and antibonding electrons are equal.
- **3.** (1)

5. (6)  $2XeF_6 + SiO_2 \longrightarrow 2XeOF_4 + SiF_4$ 

# Revision Exercise (Chapter 8 to 13)

	J

SIN	GLE CORRECT ANSWER TYPE		9.	The ease of liquefaction of noble gases decreases the order	:
1	Which of the following oxides of nitrogen is paramagnet	io?		(a) $He > Ne > Ar > Kr > Xe$	ļ
1.	(a) $N_2O$ $\square$ (b) $N_2O_5$			(b) $Xe > Kr > Ar > Ne > He$	
		_		(c) $Kr > Xe > He > Ar > Ne$	]
2	(c) $NO_2$ $\Box$ (d) $N_2O_3$			(d) $Ar > Kr > Xe > He > Ne$	□ .

	(a) H <sub>2</sub> S is a gas while H <sub>2</sub>	O is a liquid			(a) H <sub>2</sub> SO <sub>4</sub> is stronger than HI
	(b) H—S bond is weaker				(b) HI is stronger than H <sub>2</sub> SO <sub>4</sub> □
	(c) H <sub>2</sub> O is highly associa	-			(c) H <sub>2</sub> SO <sub>4</sub> is an oxidising agent □
	(d) molecular mass of H <sub>2</sub>	$_{2}S$ is more than that of $H_{2}O$			(d) HI is a reducing agent
26.	In ozone, there are:			38.	Mark out the incorrect match of shape:
	(a) $2\sigma$ and $1\pi$ bonds	$\Box$ (b) $1\sigma$ and $2\pi$ bonds			(a) ICl <sub>4</sub> : Square planar □ (b) XeOF <sub>2</sub> : Trigonal planar □
	(c) $2\sigma$ and $2\pi$ bonds				(c) $[SbF_5]^{2-}$ : Square bipyramidal
		l one lone pair of electrons			(d) $NH_2$ : Pyramidal
27.	Which of the following l	halogens is called super halog	gen?	39.	Select the correct order of reactivity:
	(a) Fluorine	☐ (b) Chlorine			(a) $HI>HBr>HCI>HF$ $\Box$ (b) $HCIO_4>HBrO_4>HIO_4$ $\Box$
	(c) Bromine	☐ (d) Iodine			(c) HClO <hbro<hio< td=""></hbro<hio<>
28.	0.1	nfected by bubbling through	water		(d) HClO <sub>4</sub> >HClO <sub>3</sub> >HClO <sub>2</sub> >HClO
	a controlled quantity of:			40.	Which of the following statements are correct?
	(a) $Br_2$	□ (b) N <sub>2</sub>			(a) Cl <sub>2</sub> reacts with aqueous Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> to form HCl and
	(c) Cl <sub>2</sub>	$\square$ (d) $O_2$			NaHSO <sub>4</sub> .
29.	Diamagnetic oxide of chl				(b) Cl <sub>2</sub> reacts with aqueous Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub> to give Na <sub>2</sub> S <sub>4</sub> O <sub>6</sub> and
	(a) ClO <sub>2</sub>	☐ (b) ClO <sub>3</sub>			NaCl.
	(c) Cl <sub>2</sub> O <sub>6</sub>	$\Box$ (d) none of these			(c) A white precipitate of silver thiosulphate is formed which
30.	The reaction of XeF <sub>6</sub> wit	-			changes to yellow, brown and finally black when silver nitrate is added to $Na_2S_2O_3$ .
	(a) XeF <sub>4</sub> and SiF <sub>4</sub>	$\Box$ (b) XeOF <sub>2</sub> and SiF <sub>4</sub>			(d) Sodium thiosulphate is quantitatively oxidised by iodine.
	(c) XeOF <sub>4</sub> and SiF <sub>4</sub>	☐ (d) none of these			(a) Sociali anosaiphae is quantitatively oxidised by founde.

#### ASSERTION-REASON TYPE QUESTIONS

The questions given below consist of an Assertion (A) and Reason (R). Use the following key for the appropriate answer of each question.

- (a) Both (A) and (R) are correct and (R) is the correct explanation of (A).
- (b) Both (A) and (R) are correct but (R) is not the correct explanation of (A).
- (c) (A) is correct but (R) is incorrect.
- (d) (A) is incorrect but (R) is correct.
- (e) Both (A) and (R) are incorrect.
- 41. (A) Lead exhibits oxidation states of +2 and +4.
  - (R) Lead exhibits inert pair effect.
- **42.** (A) Al forms  $[AlF_6]^{3-}$  but B does not form  $[BF_6]^{3-}$ .
  - (R) B does not react with fluorine.
- 43. (A) PF<sub>5</sub> and IF<sub>5</sub> have similar shapes.
  - (R) PF<sub>5</sub> has two types of P—F bond lengths.
- **44.** (A) Xenon forms three fluorides with molecular formulae XeF<sub>2</sub>, XeF<sub>4</sub> and XeF<sub>6</sub>.
  - **(R)** The formation of xenon fluorides involves the unpairing of *p*-orbitals and promotion of electron or electrons to the vacant *d*-orbitals in the outermost shell. The number of unpaired orbitals under the excited states are either 2 or 4 or 6.
- **45.** (A) Halogens combine with each other and form binary covalent compounds of  $AB_n$  type which are called interhalogen compounds. B is always smaller atom and n may have values 1 to 7.
  - (R) Interhalogen compounds are less reactive than  $A_2$  or  $B_2$  molecules.
- **46.** (A) Sulphuric acid has great affinity for water. It acts as a powerful dehydrating agent.
  - (R) Sulphuric acid has corrosive action on skin also.
- **47.** (A) Boron, aluminium and gallium form complex anionic hydrides of the type NaBH<sub>4</sub>, LiAlH<sub>4</sub> and LiGaH<sub>4</sub>, respectively.
  - (R) These complex hydrides are powerful reducing agents.
- **48.** (A) The abundance of carbon is more than silicon in earth's crust.
  - (R) Carbon has the maximum property of catenation.
- **49.** (A) All the oxidation states of nitrogen from +1 to +4 show disproportionation in acidic medium.
  - (R) Aqueous nitric acid undergoes disproportionation.
- **50.** (A) All the halogens are paramagnetic in atomic forms.
  - (R) Halogens have seven electrons in their outermost shell *i.e.*, they have  $ns^2np^5$  configuration.

#### MATRIX MATCHING QUESTIONS

51. Match Column-II with Column-III:

Column-I	Column-II	Column-III
(a) XeF <sub>2</sub>	(p) 90°	(i) Tetrahedral
(b) XeF <sub>4</sub>	(q) 109.5°	(ii) Pyramidal
(c) XeO <sub>4</sub>	(r) 103°	(iii) Linear
(d) XeO <sub>3</sub>	(s) 180°	(iv) Square planar

52. Match Column-I with Column-II:

Column-I	Column-II		
(a) $H_3PO_2$	(p) Reducing		
(b) $H_2S$	(q) Monobasic		
(c) HNO <sub>2</sub>	(r) Dibasic		
(d) HI	(s) Oxidising		

53. Match Column-I with Column-II:

Tracen Column 1 with Column 11:	
Column-I	Column-II
(a) $Zn + V$ . dil. $HNO_3$	(p) NO
(b) $Sn + dil. HNO_3$	(q) NO <sub>2</sub>
(c) $Ag + dil. HNO_3$	(r) $NH_4NO_3$
(d) Pb + conc. HNO <sub>3</sub>	(s) $Sn(NO_3)_2$
	(t) $Zn(NO_3)_2$

54. Match Column-I with Column-II:

Column-I	Column-II
(a) $NH_4NO_3$	(p) Laboratory reagent
(b) $(NH_4)_2SO_4$	(q) In making dry cells
(c) NH <sub>4</sub> Cl	(r) Fertiliser
(d) NH <sub>4</sub> OH	(s) Explosive

55. Match Column-I with Column-II:

Column-I	Column-II		
(a) $P_4O_{10}$	(p) Ionic		
(b) SiO <sub>2</sub>	(q) Covalent		
(c) $Al_2O_3$	(r) Acidic		
(d) SnO	(s) Amphoteric		

**56.** Match Column-I with Column-II:

Column-1	Column-II
(a) HF	(p) Reducing agent
(b) HI	(q) Oxidising agent
(c) Cl <sub>2</sub>	(r) Precipitate with AgNO <sub>3</sub> solution
(d) (CN) <sub>2</sub>	(s) Attacks glass
	(t) Pseudo halogen

#### LINKED COMPREHENSION TYPE

#### Passage 1

Silicates are minerals containing tetrahedral SiO<sub>4</sub><sup>4</sup> structural units. A variety of silicate structures occur in nature, ranging from single tetrahedra to pairs, rings, chains, sheets and three-dimensional networks of linked tetrahedra with cations to balance the total charge in the crystal. In aluminosilicates, aluminium atoms substitute for some of tetrahedrally bonded silicon atoms and additional cations are present in order to maintain a net charge of zero. Zeolites are network aluminosilicates having pores on a molecular scale. They are useful for exchanging ions, for separating mixtures of gases and as catalysts.

Answer the following questions:

- 57. Silicates which contain two units of SiO<sub>4</sub><sup>4</sup> joined along a corner containing oxygen are called:
  - (a) orthosilicates(b) pyrosilicates(c) cyclic silicates(d) chain silicates

- 58. The general formula of cyclic or ring silicates is:
  - (a)  $(Si_2O_5)_n^{2n}$
- (b)  $(SiO_3)_n^{2n-}$
- (c)  $(SiO_3^2)_n$
- (d) both (b) and (c)
- 59. Mark the incorrect statement:
  - (a) Zeolites are a class of three dimensional aluminosilicates which can accommodate water molecules in their cavities.
  - (b) Quartz, tridymite, feldspar, etc. are three dimensional silicates.
  - (c) Zeolites can be used to soften hard water.
  - (d) Three dimensional silicates involve three oxygen atoms of each tetrahedra for sharing with adjacent tetrahedra.

#### Passage 2

All the elements of group 13 form trihalides. The boron halides are covalent. The trifluorides of Al, Ga, In and Tl are ionic while chlorides, bromides and iodides are largely covalent when anhydrous. However, their covalent nature decreases on moving from Ga to Tl. Trihalides fume in air and undergo hydrolysis. They act as Lewis acids. They form complex halides.

Answer the following questions:

- 60. Which of the halides does not undergo hydrolysis?
  - (a) BF<sub>3</sub>

(b) BCl<sub>3</sub>

(c) AlF<sub>3</sub>

- (d) AlCl<sub>3</sub>
- **61.** Which of the following statements about anhydrous aluminium chloride is correct?
  - (a) It exists as AlCl<sub>3</sub> molecule.
  - (b) It is not easily hydrolysed.
  - (c) It sublimes at 100°C under vacuum.
  - (d) It is a strong Lewis base.
- **62.** Which of the following statements is correct?
  - (a) Both AlCl<sub>3</sub> and BCl<sub>3</sub> are not Lewis acids.
  - (b) Both AlCl<sub>3</sub> and BCl<sub>3</sub> are equally strong Lewis acids.
  - (c) AlCl<sub>3</sub> is stronger Lewis acid than BCl<sub>3</sub>.
  - (d) BCl<sub>3</sub> is stronger Lewis acid than AlCl<sub>3</sub>.

#### Passage 3

The chemistry of fluorine differs sharply from the other halogens. Fluorine atoms form weak bonds to other fluorine atoms but particularly strong bonds to most other kinds of atoms. Fluorine displaces other halogens from their compounds and oxidises elements in compounds exposed to it. The compounds of fluorine with metals in their lower oxidation states are salts with strong ionic character. The higher oxidation states of many of the

same elements yield volatile fluorides with significant covalent character.

Compounds of fluorine with the non-metals possess a wide range of reactivities and molecular geometries. SF<sub>6</sub> is an inert compound while BF<sub>3</sub> is a strong lewis acid. SbF<sub>5</sub> is a strong fluorinating agent. PtF<sub>6</sub>, a strong fluorinating agent has opened up modern research on the compounds of the noble gases.

Answer the following questions:

- **63.** Which can bring the highest oxidation state in the transition metal?
  - (a)  $F_2$

(b) Cl<sub>2</sub>

(c) Br<sub>2</sub>

- (d) I<sub>2</sub>
- **64.** Among the fluorides given below which will further react with F<sub>2</sub>:
  - (a) NaF

(b) CaF<sub>2</sub>

(c) SF<sub>6</sub>

- (d)  $\mathbf{IF}_5$
- 65. Which one of the following reactions does not occur?
  - (a)  $F_2 + 2Cl^- \longrightarrow 2F^- + Cl_2$
  - (b)  $Cl_2 + 2F^- \longrightarrow 2Cl^- + F_2$
  - (c)  $Cl_2 + 2Br^- \longrightarrow 2Cl^- + Br_2$
  - (d)  $F_2 + 2Br^- \longrightarrow 2F^- + Br_2$

#### **INTEGER ANSWER TYPE**

- **66.** How many  $\pi$ -bonds are present in the molecule of borazine?
- **67.** The number of isomers possible for disubstituted borazine,  $B_3N_3H_4X_2$  is:
- **68.** Red lead reacts with conc. HCl according to following reaction,

$$Pb_3O_4 + HCl \longrightarrow XPbCl_2 + Cl_2 + H_2O$$

Balance this reaction and find the value of X.

- 69. What is the basicity of phosphorus acid?
- **70.** How many sigma bonds are present in the molecule of caro's acid?
- 71. What is the oxidation state of S in  $H_2SO_4$ ?
- **72.** How many lone pairs of electrons are present in central atom of ClF<sub>3</sub>?

# Answers with Hints

- 1. (c) NO<sub>2</sub> is paramagnetic due to the presence of unpaired electron.
- 2. (b) CaF<sub>2</sub> in the system acts as a thinner. It lowers the temperature of the melt and makes it more conducting.
- 3. (c)  $SO_2$   $H_2O$   $H_2S$   $NH_3$   $sp^2$   $sp^3$   $sp^3$   $sp^3$   $sp^3$  119.5° 104.5° 92.5° 107.5°
- 4. (d)
  5. (a)  $XeF_4$   $sp^3d^2$  Square planar  $XeF_6$   $sp^3d^3$  Distorted octahedral  $XeO_3$   $sp^3$  Pyramidal
- $XeO_3$   $sp^3$  Pyramidal  $XeO_4$   $sp^3$  Tetrahedral

(One S=O bond)

- **7.** (c)
- 8. (c) 4P + 5O<sub>2</sub> → P<sub>4</sub>O<sub>10</sub> + light

  The phenomenon of emitting light as a result of chemical change is called chemiluminescence.
- 9. (b) Ease of liquefaction increases in the group from top to bottom as van der Waals' forces increase with increase of atomic size.
- **10.** (b) Due to poor shielding effect of *d*-electrons the outer electrons in Ga experience more attraction by the nucleus.
- 11. (d) Ge(IV) is more stable than Ge(II) while Pb(II) is more stable than Pb(IV).
- 12. (d) Fluorine does not form oxoacid.
- 13. (d)  $Na_2B_4O_7 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2B_4O_7$

$$H_2B_4O_7 + 5H_2O \longrightarrow 4H_3BO_3$$
  
 $2H_3BO_3 \xrightarrow{\text{Heat}} B_2O_3 + 3H_2O$   
 $B_2O_3 + 6Na \longrightarrow 2B + 3Na_2O$ 

14. (d) The bond angle in the hydrides vary in the order :

$$NH_3 > PH_3 > AsH_3 > SbH_3$$

In the formation of  $XH_4^+$ , the bond angle becomes  $109^{\circ}28'$  Hence maximum increase will occur in SbH<sub>3</sub>.

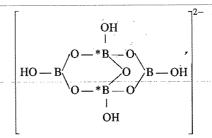

15. (c) 
$$2KI + Cl_2 \longrightarrow 2KCI + I_2$$

$$I_2 + CHCl_3 \longrightarrow Violet layer$$

$$Cl_2 + H_2O \longrightarrow 2HCl + [O]$$

$$I_2 + H_2O + 5[O] \longrightarrow 2HIO_3$$

- 16. (b)  $PI_3 + 3H_2O \longrightarrow 3HI + H_3PO_3$ (Monobasic) (Dibasic)
- 17. (c) Borax ion can be represented as:

Thus, borax contains two B-atoms having an octet of electrons.

18. (a) 
$$B_2H_6 + NH_3 \longrightarrow B_2H_6 \cdot 2NH_3$$

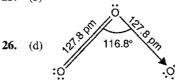

$$High temp. (BN)_x$$

$$B_2H_6 \cdot 2NH_3 \xrightarrow{High} B_3N_3H_6$$

- **19.** (b)
- **20.** (c)

21. (a) 
$$PCl_5 + H_2O \longrightarrow POCl_3 + 2HCl$$
  
 $(1 : 1)$   $PCl_5 + 4H_2O \longrightarrow H_3PO_4 + 5HCl$   
 $(1 : 4)$ 

- **22.** (d)  $ICl_{4}^{-}$   $SO_{3}$   $NO_{3}^{-}$   $SO_{4}^{2-}$   $PO_{4}^{3-}$   $sp^{3}$   $sp^{3}$   $sp^{3}$
- **23.** (a)
- 24. (a) NO  $N_2O_4$  NO $_3^-$  NO $_2^-$ Bond length 115 pm 117 pm 122 pm 121 pm
- **25.** (b)

- 27. (a) 28. (c) 29. (c)
- 30. (c)  $2XeF_6 + SiO_2 \longrightarrow 2XeOF_4 + SiF_4$
- **31.** (c, d)
- 32. (a, b, c)
- 33. (c, d) Graphite has sigma and  $\pi$ -bonds. The  $\pi$ -electrons are free to move throughout the entire layers.
- **34.** (a, d) Silicon hydrides are known as silanes. Buckminsterfullerene is diamagnetic as it does not have unpaired electrons.
- 35. (a, b)  $(NH_4)_2Cr_2O_7 \xrightarrow{\text{heat}} N_2 + Cr_2O_3 + 4H_2O_3$

36. (a, b, c) 
$$P_4O_{10} \xrightarrow{2H_2O} 4HPO_3 \xrightarrow{2H_2O} 2H_4P_2O_7$$

Metaphosphoric acid

$$4H_3PO_4 \xleftarrow{2H_2O}$$
Orthophosphoric

37. (c, d) 
$$2HI + H_2SO_4 \longrightarrow I_2 + SO_2 + 2H_2O$$
Reducing Oxidising agent

38. (b, d) 
$$XeOF_2 - sp^3d \longrightarrow T$$
-shaped  $NH_2^- - sp^3 \longrightarrow V$ -shaped

**40.** (a, c, d) 
$$Na_2S_2O_3 + 4Cl_2 + 5H_2O \longrightarrow 2NaHSO_4 + 8HCl$$
  
 $2AgNO_3 + Na_2S_2O_3 \longrightarrow Ag_2S_2O_3 + 2NaNO_3$   
 $Ag_2S_2O_3 + H_2O \longrightarrow Ag_2S + H_2SO_4$   
 $2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$ 

**41.** (a)

**42.** (c) B does not have d-orbitals.

43. (d) PF<sub>5</sub> has trigonal bipyramidal shape having two types of P—F bond lengths.
IF<sub>5</sub> has square pyramidal shape.

**44.** (a)

**45.** (e) Assertion is wrong as n may have values 1, 3, 5 and 7. Reason is also wrong as interhalogen compounds are more reactive than  $A_2$  or  $B_2$  molecules as A—B bond is weaker than A—A and B—B bonds.

**46.** (b)

**47.** (b)

**48.** (d) Carbon is less abundant than silicon in the earth's crust, however, compounds of carbon are very large due to catenation property.

**49.** (c) (A) is correct while (R) is incorrect. In HNO<sub>3</sub>, the oxidation state of nitrogen is +5.

**50.** (a)

**51.** (a-s-iii); (b-p-iv); (c-q-i); (d-r-ii)

**52.** (a-p, q); (b-p, r); (c-p, q, s); (d-p, q)

53. (a-r, t); (b-r, s); (c-p); (d-q)

**54.** (a-r, s); (b-p, r); (c-p, q); (d-p)

**55.** (a-q, r); (b-q, r); (c-p, s); (d-p, s)

**56.** (a-s); (b-p, r); (c-q); (d-q, t)

**57.** (b)

58. (d)

**59.** (d)

60. (a) BF<sub>3</sub> forms an addition product with water as B—F bond is very strong.

$$BF_3 + H_2O \Longrightarrow H^+[BF_3OH]$$

**61.** (c)

**62.** (d)

**63.** (a)

**64.** (d)  $IF_5 + F_2 \longrightarrow IF_7$ 

65. (b)

66. Three: Borazine has structure similar to benzene.

67. Four: See objective question 15 on Page 407.

**68.** Three:  $Pb_3O_4 + 8HCl \longrightarrow 3PbCl_2 + Cl_2 + 4H_2O$ 

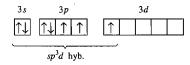

69. Two: H<sub>3</sub>PO<sub>3</sub> is a dibasic acid. It forms two series of salts.

**70.** Seven:  $H_2SO_5$  is represented as:

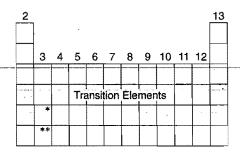

$$\begin{array}{c} O \\ H \xrightarrow{\sigma} O \xrightarrow{\sigma \parallel} S \xrightarrow{\sigma} O \xrightarrow{\sigma} O \xrightarrow{\sigma} H \\ O \end{array}$$

**71.** Six

72. Two: Cl in first excited state

# Transition Elements or d-block Elements and f-block Elements

## 14.1 INTRODUCTION

In the extended form of the periodic table, the elements have been grouped into four blocks namely s, p, d and f-blocks. The elements belonging to groups 3 to 12 are called **d-block** or **transition elements**. These are present between s-block and p-block elements. The properties of these elements are intermediate between the properties of s-block and p-block elements, i.e., d-block elements represent change or transition in properties from most electropositive s-block elements to least electropositive p-block elements. Therefore, these elements are called **transition elements**.

Previously the transition elements were regarded as those elements which possessed partially filled penultimate d-subshells in their ground state or in one of their commonly occurring oxidation states. This definition included coinage metals (Cu, Ag and Au) in the transition elements as their ions have partially filled (n-1)d-subshells although their atoms have filled (n-1)d-subshells in the ground state.

Cu	$3d^{10}4s^1$	Cu <sup>2+</sup>	$3d^{9}$
Ag	$4d^{10}5s^1$	Ag <sup>2+</sup>	$4d^9$
An	$5d^{10}6s^1$	Au <sup>3+</sup>	$4d^8$

However, the above definition does not cover the elements of group 12, *i.e.*, zinc metals (Zn, Cd and Hg) as these elements do not have partially filled (n-1)d-subshells either in the ground state or in ions.

Zn	$3d^{10}4s^2$	$Zn^{2+}$	$3d^{10}$
Cd	$4d^{10}5s^2$	Cd <sup>2+</sup>	$4d^{10}$
Hg	$5d^{10}6s^2$	Hg <sup>2+</sup>	$5d^{10}$

However, zinc metals showing similarities in some of chemical properties with transition metals are also included in this block. These are considered as end members of the transition series in order to maintain a rational classification of elements.

Forty elements belong to *d*-block. Fourth, fifth, sixth and seventh periods consist of ten elements each.

	]	d-block Transition elements									
	III B	IV B	V B 5	VI B	VII B 7	8	VIII 9	10	I B 11	II B 12	
	21 Sc	22 <b>T</b> i	23 V	24 Cr	25 Mn	26 Fe	27 Co	28 Ni	29 Cu	30 Zn	
s-block	39 Y	40 Zr	41 Nb	42 Mo	43 Tc	44 Ru	45 Rh	46 Pd	47 Ag	48 Cd	p-block
	57 La	72 Hf	73 Ta	74 W	75 Re	76 Os	77 Ir	78 Pt	79 Au	80 Hg	
;	89 Ac	104 Ku	105 Ha	106 Sg	107 Bh	108 Hs	109 Mt	110 Uun	111 Uuu	112 Uub	

The *d*-block elements include the most common metal used in construction and manufacturing (iron), metals that are valued for their beauty (gold, silver and platinum), metals used in coins (nickel, copper) and metals used in modern technology (titanium). Copper, silver, gold and iron were known and used in early civilization. This group contains the densest elements (osmium,  $d = 22.59 \text{ g cm}^{-3}$  and iridium,  $d = 22.61 \text{ g cm}^{-3}$ ), the metals with the highest and lowest melting points (tungsten, m.p. =  $3410^{\circ}$ C and mercury, m.p. =  $-38.9^{\circ}$ C) and radioactive elements such as technetium and ten members of seventh period.

Certain d-block elements are particularly important in living organisms. Iron, the transition element, is present in the largest quantity in the human body. The best known biological ironcontaining compound is the protein haemoglobin, the red component of blood that is responsible for the transport of oxygen. Cobalt is the crucial element in vitamin B<sub>12</sub>, a compound that acts as a catalyst in the metabolism of carbohydrates, fats and proteins. Molybdenum and iron together with sulphur form the reactive portion of nitrogenase, a biological catalyst used by nitrogen fixing organisms to convert atmospheric nitrogen into ammonia. Copper and zinc are important in other biological catalysts. Iron, zinc, copper, cobalt, nickel, manganese and molybdenum are known to be essential components of enzymes. Vanadium and chromium are also essential for life. Some bad elements are also present in this block. For example, mercury is toxic and is threat to the environment.

## 14.2 ELECTRONIC CONFIGURATION

In the transition elements, the last differentiating electron is accommodated on penultimate *d*-orbitals, *i.e.*, *d*-orbitals are successively filled. The general electronic configuration of transition elements is:

$$(n-1)d^{1-10} ns^{0,1 \text{ or } 2}$$

There are four complete rows (called series) of ten elements each corresponding to filling of 3d, 4d, 5d and 6d-orbitals respectively. Each series starts with a member of group third (IIIB) and ends with a member of group twelve (IIB).

**First transition or** 3d**-sc ies :** This series consists of elements from Sc(21) to Zn(30). 3d-orbitals are gradually filled up.

Element	Symbol	At. No.	•	Electronic configuration
Scandium	Sc	21		$1s^2$ , $2s^22p^6$ , $3s^23p^63d^1$ , $4s^2$
			_	or [Ar] $3d^{1}4s^{2}$
Titanium	Ti	22	ď.	[Ar] $3d^24s^2$
Vanadium	V	- 23	filled	$[Ar] 3d^34s^2$
Chromium	Cr*	24		[Ar] $3d^54s^1$
Manganese	Mn	25	are	[Ar] $3d^54s^2$
Iron	Fe ·	26	tals	$-[Ar] 3d^64s^2$
Cobalt	Co	27	3d-orbitals	[Ar] $3d^{7}4s^{2}$
Nickel	Ni	28	-pg	[Ar] $3d^84s^2$
Copper	Cu*	29		[Ar] $3d^{10}4s^1$
Zinc	Zn	30	4	[Ar] $3d^{10}4s^2$

The configuration of Cr and Cu are different than expected. The actual configurations are explained on the basis of stability concept of half-filled or completely filled (n-1)d-orbitals. (n-1)d-subshell is more stable when 5 or 10 electrons are present, *i.e.*, every d-orbital is either singly occupied or doubly occupied.

**Second transition or 4***d***-series :** This series consists of elements from Y(39) to Cd(48). 4*d*-orbitals are gradually filled up.

Element	Symbol	At. No.	Electronic configuration
Yttrium	Y	39	[Kr] $4d^1 5s^2$
Zirconium	Zr	40	[Kr] $4d^2 5s^2$
Niobium	${ m Nb}^*$	41 🚊	[Kr] $4d^4 5s^1$
Molybdenum	Mo <sup>*</sup>	42	[Kr] $4d^5 5s^1$
Technetium	Tc*	42 de lilled	[Kr] $4d^6 5s^2$
Ruthenium	Ru*	1 /1/1 1	$[Kr] 4d^7 5s^1$
Rhodium	Rh*	45 46 47 44-orbitals	[Kr] $4d^8 5s^1$
Palladium	Pd*	46 7	[Kr] $4d^{10} 5s^0$
Silver	Ag*	47 7	[Kr] $4d^{10} 5s^1$
Cadmium	Cd	48	[Kr] $4d^{10} 5s^2$

Elements marked with asterisk have anomalous configurations. These are attributed to factors like nuclear-electron and electron-electron forces.

**Third transition or 5***d***-series:** This series consists of elements from La(57) to Hg(80) except 14 elements of lanthanide series from Ce(58) to Lu(71). 5*d*-orbitals are gradually filled up.

Element	Symbol	At. No.	Electronic configuration
Lanthanum	La	57	[Xe] $5d^1 6s^2$
Hafnium	Hf	72 g	[Xe] $4f^{14} 5d^2 6s^2$
Tantalum	Ta	73 👨	[Xe] $4f^{14} 5d^3 6s^2$
Tungsten	w	74 👸	[Xe] $4f^{14} 5d^4 6s^2$
Rhenium	Re	75 eg	[Xe] $4f^{14} 5d^5 6s^2$
Osmium	Os	1 7/	[Xe] $4f^{14} 5d^6 6s^2$
Iridium	Ir	76 77 78 79 79 79 79 79 79 79 79 79 79 79 79 79	[Xe] $4f^{14} 5d^7 6s^2$
Platinum	Pt*	78 💆	[Xe] $4f^{14} 5d^9 6s^1$
Gold	Au*	79 5	[Xe] $4f^{14} 5d^{10} 6s^1$
Mercury	Hg	80	[Xe] $4f^{14} 5d^{10} 6s^2$

**Fourth transition or 6d-series:** This series consists of elements from Ac(89) to Uub(112) except 14 elements of actinide series from Th(90) to Lr(103). 6d-orbitals are gradually filled up.

	•		
Element	Symbol	At. No.	Electronic configuration
Actinium	Ac	89	[Rn] $6d^1 \overline{7s^2}$

Ununbium	Uub <sup>*</sup>	112	[Rn] $5f^{14} 6d^{10} 7s^2$

<sup>\*</sup>IUPAC names

The elements from atomic numbers 106 to 112 have recently been reported but these heavy elements are very unstable.

It is evident from the above electronic configurations that in transition elements ns-orbital is filled before (n-1)d-orbitals. Fig. 14.1 tells that near about atomic number 20, 4s-subshell has somewhat lower energy than 3d-subshell. Due to this, in potassium (Z=19) and calcium (Z=20), 4s-subshell is filled

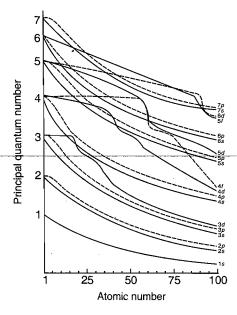

Fig. 14.1 The relative energies of the atomic orbitals as a function of atomic number

before 3*d*-subshell. Therefore, the electronic configurations of potassium and calcium are:

Potassium	19	$1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$
Calcium	20	$1s^2 2s^2 2p^6 3s^2 3p^6 4s^2$

Beyond calcium, the energy of 3d-subshell is less than the energy of 4s and 4p-orbitals. Thus, 3d-orbitals are filled from scandium (Z=21) to zinc (Z=30). The filling of the 3d-orbitals proceeds one at a time. The d-orbitals are first occupied singly and then pairing starts. However, in two cases, chromium (Z=24) and copper (Z=29), one electron is present on 4s-orbital.

The unusual filling patterns in chromium and copper lead us to conclude that half filled and fully filled subshells are unexpectedly stable.

In the first series, 3*d*-electrons become more effective in shielding 4*s*-electrons from the nucleus, *i.e.*, 3*d*-electrons suffer more attraction than 4*s*-electrons from nucleus. This is apparent from the fact that when atoms of the elements from atomic

<sup>†</sup>American names

number 21 to 30 change into cations, the 4s-electrons are lost first before 3d-electrons, although 4s-subshell was filled earlier.

Mn	25	$(3d^54s^2)$	Mn <sup>2+</sup>	$3d^{5}$
Fe	26	$(3d^64s^2)$	Fe <sup>2+</sup>	$3d^6$
Ni	28	$(3d^84s^2)$	Ni <sup>2+</sup>	$3d^{8}$

The same thing is repeated in second transition series, *i.e.*, in the 5th period, the 5s-subshell is filled before 4d-subshell. In rubidium (Z = 37) and strontium (Z = 38), 5s-subshell is filled. 4d-subshell is gradually filled from yttrium (Z = 39) to cadmium (Z = 48). In 6th period, 6s-subshell is filled first before any electron is accommodated on 5d or 4f-orbitals. In lanthanum (Z = 57), the energies of 4f, 5d and 6s are very close to one another and after filling 6s-orbital in caesium (Z = 55) and barium (Z = 56), the next electron in lanthanum is accommodated on 5d-orbitals. In the subsequent elements from cerium (Z = 58) to lutetium (Z = 71) 4f-orbitals are gradually filled. From hafnium (Z = 72), the 5d-orbitals are filled. This process is completed in mercury.

Hf 72 
$$4f^{14}5d^26s^2$$
  
Hg 80  $4f^{14}5d^{10}6s^2$ 

Similar pattern in fourth transition series is observed.

The fourteen elements following lanthanum (Z = 57) from cerium (58) to lutetium (Z = 71) constitute the **first inner transition series.** These are also called **lanthanides.** In these elements 4f-orbitals are being filled successively. Similarly, the fourteen elements following actinium (Z = 89) from thorium (Z = 90) to lawrencium (Z = 103) constitute the second inner transition series. These are also called **actinides.** In these elements 5f-orbitals are successively filled.

#### ■ Conclusions

(i) An inner core of electrons with noble gas configuration is present.

Series	Inner core with noble gas
3 <i>d</i>	[Ar]
4 <i>d</i>	[Kr]
5d	[Xe]
6 <i>d</i>	[Rn]

- (ii) (n-1)d orbitals are filled up gradually with electrons, *i.e.*, configuration varies from  $(n-1)d^1$  to  $(n-1)d^{10}$ . Each series accommodates ten elements each.
- (iii) Most of the elements possess two electrons in the outermost orbital, *i.e.*,  $ns^2$ . However, some of the elements such as Cr, Cu, Nb, Mo, Tc, Ru, Rh, Ag, Pt, Au and Uuu have one electron in the outermost orbital, *i.e.*,  $ns^1$  while one element palladium has no electron on ns orbital.

# 14.3 GENERAL CHARACTERISTICS OF TRANSITION ELEMENTS

The members belonging to a given transition series do not differ so much from one another as those of representative elements of the same period. It is due to the fact that in a transition series, there is no change in the number of electrons of outermost shell and only change occurs in the (n-1)d electrons from member to member in a period. These elements show horizontal and vertical relationships or they show similarities in a period as well as in group. The general trends of some of the important properties are discussed here first in the respective periods and then in groups.

#### 1. Metallic Character

All the transition elements are metals. They exhibit most of the properties of metals. They possess metallic lustre, high density, high melting and boiling points, malleability, ductility, high tensile strength, hardness, brittleness, etc. They are good conductors of heat and electricity. They exhibit all the three types of structures: face centred cubic (fcc), hexagonal closed packed (hcp) and body centred cubic (bcc). These properties reveal that both metallic and covalent bonding are present in the atoms of transition elements.

The metallic bonding is due to possession of one or two electrons in the outermost energy shell like alkali and alkaline earth metals and relatively low ionisation energies. Copper, silver and gold are outstanding in their thermal and electrical conductivities. The properties of hardness and brittleness are associated with covalent bonding. The presence of unpaired and unfilled d-orbitals favours covalent bonding. Greater the number of unpaired d electrons, greater the number of covalent bonds and therefore, greater is the strength of these bonds. Cr, Mo and W are very hard metals as they have maximum number of unpaired d-orbitals while Zn, Cd and Hg are softer in nature as they do not have any unpaired d-orbitals.

#### 2. Atomic Radii

The atomic radii for transition metals are smaller than their corresponding s-block elements.

	s-block elements		Transitio	n metals
4th period	K	Ca	Sc	Cu
At. radius (pm)	203	174	144	117

The atomic radii\* of the elements of a given series decrease with increase in atomic number but this decrease becomes small after midway. In the first transition series, the atomic radius gradually decreases from scandium to chromium but from chromium to copper, it is nearly the same. Similar behaviour has been observed in the second and third transition series.

3d-series	At. radii (pm)	4d-series	At. radii (pm)	5d-series	At. radii (pm)
Sc	144	Y	162	La	168
Ti	132	Zr	145	Hf	144
V	122	Nb	134	Ta	134
Cr	117	Mo	130	w	130
Mn	117	Tc	*************	Re	128
Fe	117	Ru	125	Os	126
Co	116	Rh	125	Ir	1 <b>26</b>
Ni	115	Pd	128	Pt	129
Cu	117	Ag	134	Au	134
Zn	125	Cd	141	Hg	144

<sup>\*</sup> Covalent radii

The decrease in atomic radii in each series, in the beginning, is due to an increase in nuclear charge from member to member which tends to pull the ns electrons inward, i.e., it tends to reduce the size. At the same time, the addition of extra electrons to (n-1)d-orbitals also provides the screening effect. As the number of d electrons increases, the screening effect increases. Thus, there are operating two effects namely screening effect and nuclear charge effect which oppose each other. In the midway onwards of the series both these effects become nearly equal and thus, there is no change in atomic radii inspite of the fact that atomic number increases gradually.

The values of atomic radii at the end of each series are bit higher. This is due to electron-electron repulsions among (n-1)d electrons. These repulsions become predominant at the end of each series and thus size increases. It is evident from the atomic radii values of coinage and zinc metals.

In a vertical row, the atomic radii is expected to increase from top to bottom. Therefore, the atomic radii of transition metals of second series have larger values than those of the first transition series. However, the transition metals of third series except the first member, lanthanum, have nearly the same radii as metals of second transition series above them. This is due to **Lanthanide contraction**. Due to inclusion of fourteen lanthanides between lanthanum and hafnium, [there is continuous decrease in size from Ce(58) to Lu(71)] hafnium size becomes nearly equal to the size of zirconium.

#### 2 3. Ionic Radii

The ionic radii follow the same trend as the atomic radii. For the same oxidation state, the ionic radii generally decreases as the atomic number increases in a particular transition series.

The ionic radii decreases with increase of charge on the ion.

$$Fe^{3+}(0.64) < Fe^{2+}(0.76)$$
  
 $Ni^{3+}(0.62) < Ni^{2+}(0.72)$   
 $Mn^{3+}(0.66) < Mn^{2+}(0.80)$ 

The ionic radii of the transition metals are smaller than those of representative elements belonging to same period.

#### 4. Atomic Volumes and Densities

The atomic volumes of the transition elements are low as compared with elements in neighbouring groups I and II. This is because the nuclear charge is poorly screened and so attracts all the electrons more strongly.

Element Sc Ti V Cr Mn Fe Co Ni Cu Zn At. volume (mL) 
$$15.0 \ 10.6 \ 8.3 \ 7.23 \ 7.39 \ 7.10 \ 6.70 \ 6.60 \ 7.10 \ 9.20$$
 Density (g mL<sup>-1</sup>)  $3.0 \ 4.5 \ 6.1 \ 7.20 \ 7.40 \ 7.86 \ 8.90 \ 8.90 \ 8.96 \ 7.14$ 

Consequently, the densities of transition metals are high. The densities of second row are high and third row values are still higher. The two elements osmium and iridium have highest densities  $22.59~g~mL^{-1}$  and  $22.61~g~mL^{-1}$  respectively. Practically all the transition elements except scandium, yttrium and titanium possess density higher than  $5~g~mL^{-1}$ .

#### 5. Melting and Boiling Points

The transition metals have very high melting and boiling points. In each series, the melting points of these metals rise to a maximum value and then decrease with increase in atomic number. However, manganese and technetium have abnormally low melting points. The melting points of most of the transition elements except Zn, Cd and Hg are above 900°C. **Tungsten** has the highest melting point (3410°C) amongst transition elements.

The high melting and boiling points of transition metals are attributed to the stronger forces that bind their atoms together. The presence of one or more unpaired d electrons contributes to higher interatomic forces on account of covalent bonding and therefore, to high melting points. [However, this concept does not explain why manganese having five unpaired d electrons possesses lower melting point than that of vanadium or cobalt which have only three unpaired d electrons. The complex structure is responsible for this abnormal behaviour.]

When no unpaired electrons are present, the melting points are low as in the case of Zn, Cd and Hg.

3d-Series Sc Ti V Cr Mn Fe Co Ni Cu Zn M.pt. (°C) 1539 1668 1900 1875 1245 1536 1495 1453 1083 419.5 B.pt. (°C) 2730 3260 3450 2665 2150 3000 2900 2730 2595 906
```

#### 6. Ionisation Energies

The ionisation energy values of majority of d-block elements lie in between those of s- and p-block elements. The d-block elements are less electropositive than s-block elements and more electropositive than p-block elements. The transition elements do not form ionic compounds so readily as s-block elements do. Unlike s-block metals, transition elements form covalent compounds as well. Generally, lower valencies are ionic and higher valencies are covalent in nature. The first ionisation potential values are tabulated below in kJ  $\operatorname{mol}^{-1}$ .

Sc	Ti	V	Сг	Mn	Fe	Co	Ni	Cu	Zn
631	656	650	652	717	762	758	737	745	906
Y	Zr	Nb	Mo	Tc	Ru	Rh	Pd	Ag	Cd
616	674	664	685	703	711	720	804	731	876
La	Hf	Ta	W	Re	Os	Ir	Pt	Au	Hg
541	760	760	770	759	840	900	870	889	1007

Ionisation potential values increase in a period from left to right. The increase, however, is not regular. For example, in the case of first transition series, the ionisation potential values of Sc, Ti, V and Cr are fairly close to one another. Similarly, values of Fe, Co, Ni and Cu are almost similar.

The increase in the ionisation potential values in a given transition series is explained on the basis of increasing nuclear

charge and screening effect of (n-1)d electrons on ns electrons. With the increase of electrons in (n-1)d-subshell, the outer ns electrons are shielded more and more. Thus, the effect of increasing nuclear charge is somewhat neutralised by the additional screening effect and consequently, ionisation potential increases but quite slowly among a period of d-block elements. The value of zinc is appreciably higher due to additional stability associated with completely filled 3d-level in zinc. Slight variations that occur in ionisation potential values are mainly due to the slight changes in atomic radii.

Second and third ionisation energies, in general, also increase in a series. However, exceptions are observed.

3d series	Ind ionisation energy (kJ mol <sup>-1</sup> )	IIIrd ionisation energy (kJ mol <sup>-1</sup> )
Sc	1245	2451
Ti	1320	2721
$\mathbf{v}$	1376	2874
Cr	1635	2995
Mn	1513	3258
Fe	1564	2964 -
Co	1648	3238
Ni	1757	3401
, Cu,	1962	3561
Zn	1736	3839

Third ionisation energy of manganese is very high. This is because the third electron is to be removed from a stable configuration,  $(Mn^{2+}, 3d^5)$ , *i.e.*, half-filled 3d-subshell.

The second ionisation potential values of Cu and Cr are sufficiently higher than those of neighbouring elements. This is because of the electronic configuration of  $Cu^+$  which is  $3d^{10}$  (completely filled) and of  $Cr^+$  which is  $3d^5$  (half-filled), *i.e.*, for the second ionisation potential, the electron is to be removed from very stable configurations.

In vertical columns, *i.e.*, groups, the ionisation potential decreases from first member to second member in most of the cases as expected, however, the third member has higher value than second member. This is due to lanthanide contraction, *i.e.*, the atomic radii of the elements of the same group of the second and third transition series are nearly the same but atomic numbers differ by 32. Thus, the outer electrons are held very firmly and the ionisation potential values are very high. On account of this, the members of 5d are inert under ordinary conditions, *i.e.*, Pt, Au, Hg, etc., are noble metals.

#### 7. Standard Reduction Potentials

In solution, the stability of the compounds depends upon electrode potentials. Electrode potential value depends upon enthalpy of sublimation of the metal, the ionisation enthalpy and hydration enthalpy, *i.e.*,

$$M(s) \longrightarrow M^{+}(aq) + e \Delta H_{T}$$
 (Total energy change)

This process involves three steps:

First step

 $M(s) \longrightarrow M(g)$   $\Delta H_{\text{sub}}$  (Energy of sublimation) Second step

 $M(g) \longrightarrow M^{+}(g) + e$  I.E. (Ionisation energy) Third step

 $M^+(g) + aq \longrightarrow M^+(aq) \quad \Delta H_{\text{hyd}}$  (Hydration energy) Thus,  $\Delta H_T = \Delta H_{\text{sub}} + \text{I.E.} + \Delta H_{\text{hyd}}$ 

 $\Delta H_T$  is the total energy change when solid metal, M is brought in the aqueous medium in the form of monovalent ion,  $M^+(aq)$ .

The smaller the value of total energy change for a particular oxidation state in aqueous solution, greater will be the stability of that oxidation state. The electrode potentials are the measure of total energy change. Hence, quantitatively, the stability of the transition metal ions in different oxidation states in solution can be determined on the basis of the electrode potential data. The lower the electrode potential, i.e., more negative the standard reduction potential of the electrode, more stable is the oxidation state of the transition metal in the aqueous medium. The standard reduction potential values,  $E^{\circ}(M^{2+}/M)$  and  $(M^{3+}/M^{2+})$  of the members of first transition series are given below:

Element Ti V Cr Mn Fe Co Ni Cu Zn  $E^{\circ} (M^{2+}/M)V$  -1.63 -1.18 -0.91 -1.18 -0.44 -0.28 -0.25 +0.34 -0.76  $E^{\circ} (M^{3+}/M^{2+})V$  0.37 0.26 -0.41 +1.57 +0.77 +1.97 -- --

# ■ Trends in M<sup>2+</sup>/M Standard Electrode Potentials

- (i) It is evident that there is no regular trend in the  $E^{\circ}(M^{2+}/M)$  values. This is due to irregular variation of ionisation energies and sublimation energies of the atoms of the members of the transition series.
- (ii) Except copper, all other elements have negative reduction potential values, *i.e.*, these elements except copper should have the capacity to liberate hydrogen from dilute acids.

$$M + 2H^+$$
 (from acid)  $\longrightarrow M^{2+} + H_2 \uparrow$ 

In actual practice, the rate of liberation of hydrogen is very slow. Some of the metals, in fact, get protected by the formation of a thin film of an inert oxide on the surface. Chromium, for example, in spite of its high negative reduction potential value is an unreactive metal as it does not liberate hydrogen due to a thin coating of  $\text{Cr}_2\text{O}_3$  on its surface.

Copper having positive  $E^{\circ}$  value, does not liberate hydrogen from acids. It reacts only with oxidising acids such as HNO<sub>3</sub> and conc. H<sub>2</sub>SO<sub>4</sub>.

THERM	OCHEMIC	CAL	DATA	(kJ	$mol^{-1}$ )	<b>FOR</b>
FIRST	SERIES	OF	<b>TRANS</b>	ITIO	N MET	ALS

Element (M)	ΔH <sub>sub</sub> (M)	LE. <sub>(i)</sub>	LE. <sub>(ii)</sub>	$\Delta H_{\text{hyd}}$ $(M^{2+})$
Ti	469	661	1310	1866
V	515	648	1370	-1895
Cr	398	653	1590	-1925
Mn	279	716	1510	-1862
Fe	418	762	1560	-1998
Co	427	757	1640	-2079
Ni	431	736	1750	-2121
Cu	339	745	1960	-2121
Zn	130	908	1730	-2059

- (iii) Less negative of  $E^{\circ}$  values along the series is due to increase in the first and second ionisation energies.
- (iv) The values of  $E^{\circ}$  for Mn, Zn and Ni are more negative than expected. This is due to extra stability of half-filled d-subshell ( $d^{5}$ ) in (Mn<sup>2+</sup>) and completely filled ( $d^{10}$ ) in Zn<sup>2+</sup>. The high value in Ni can be attributed due to high hydration energy.
- (v) In spite of the fact that all the metals except copper have negative  $E^{\circ}$  values, but are not good reducing agents in comparison to s-block elements. This is on account of high enthalpy of sublimation, high enthalpy of ionisation and poor enthalpy of hydration.

# ■ Trends in (M³+/M²+) Standard Electrode Potentials

- (i)  $E^{\circ}$  value for  $Sc^{3+}/Sc^{2+}$  is very low. Hence,  $Sc^{3+}$  is stable. This is due to its noble gas configuration.
- (ii)  $E^{0}$  value for  $Mn^{3+}/Mn^{2+}$  is high. This reflects that  $Mn^{2+}$  state is stable due to  $d^{5}$  configuration.
- (iii)  $E^{\circ}$  values for the redox couple  $M^{3+}/M^{2+}$  indicate that  $Mn^{3+}$  and  $Co^{3+}$  ions are strong oxidising agents.

#### 8. Oxidation States

The transition elements with the exception of a few show a large number of oxidation states. The various oxidation states are related to the electronic configuration of their atoms. The oxidation states of the members of first transition series are tabulated below. The oxidation states within brackets are not stable. The highest oxidation states are found in compounds with fluorine and oxygen because fluorine and oxygen are most electronegative in nature.

The variable oxidation states of a transition metal is due to the involvement of (n-1)d and outer ns electrons in bonding as the energies of ns and (n-1)d subshells are nearly equal. The lower oxidation state is generally shown by when ns-electrons participate in bonding and higher oxidation states are exhibited when ns and (n-1)d-electrons take part in bonding.

Element		Outer electronic configuration	Oxidation states
Sc	$3d^1,4s^2$	$\uparrow$ $3d$ $4s$	(+2), +3
Ti	$3d^2,4s^2$	$ \begin{array}{c cccc}  & & & & & & & & \\  & \uparrow & \uparrow & & & & & & \\  & \uparrow & \downarrow & & & & & \\  & \uparrow & \downarrow & & & & & \\ \end{array} $	(+2), +3, +4
v	$3d^3$ , $4s^2$	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	+2, +3, +4, +5
Cr	$3d^5, 4s^1$	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	(+1), +2, +3, (+4), (+5), +6
Mn	$3d^5,4s^2$	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	+2, +3, +4, (+5), +6, +7
Fe	$3d^6,4s^2$	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	+2, +3, (+4), (+5), (+6)
Co	$3d^{7},4s^{2}$	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	+2, +3, (+4)
Ni	$3d^8,4s^2$	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	+2, +3, +4
Cu	$3d^{10},4s^1$	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	+1, +2
Zn	$3d^{10},4s^2$	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	+2

From the survey of the oxidation states of transition elements, the following conclusions are drawn:

- (i) Generally, within the transition series, the highest oxidation state increases with increase of atomic number, reaching to a maximum in the middle and then starts decreasing. For example, in the first transition series manganese shows the maximum oxidation state of +7. The highest oxidation state shown by any transition metal is +8. Ruthenium in second transition series and osmium in the third transition series show +8 oxidation state.
- (ii) In general, the minimum oxidation state shown by a transition metal is equal to the number of ns-electrons. Except scandium, (which has +3 oxidation state) for the elements of first transition series +2 oxidation state is the most common. This state arises due to loss of 4s-electrons. However, for chromium and copper, the lowest oxidation state is +1. This is due to their electronic configurations, Cr(3d<sup>5</sup>4s<sup>1</sup>) and Cu(3d<sup>10</sup>4s<sup>1</sup>). Thus, it is evident that after scandium d-orbitals are more stable than 4s-orbital, i.e., the energy associated with 3d-subshell is less than that of 4s-subshell.
- i.e., upto manganese (3d-subshell is no more than half-filled), the maximum oxidation state is equal to the sum of the 4s and 3d-electrons. For example, maximum oxidation state for titanium is  $+4 (3d^24s^2)$ , for vanadium  $+5(3d^34s^2)$ , for chromium  $+6(3d^54s^1)$  and for manganese, it is  $+7 (3d^54s^2)$ . For the remaining five elements the maximum oxidation state is not related to their electronic configurations. The common oxidation states for the elements from Fe to Ni are +2 or +3. The oxidation state higher than +3 is rarely shown.

(iii) In the first five elements of the first transition series,

- (iv) Some of the transition metals form compounds in zero oxidation state. The common examples are Ni(CO)<sub>4</sub> and Fe(CO)<sub>5</sub> in which nickel and iron are in zerovalent state.
- (v) In +2 and +3 oxidation states, the bonds formed are mostly ionic. On the other hand, in higher oxidation states, the bonds formed are essentially covalent. Higher states are usually attained with elements of high electronegativity such as fluorine and oxygen. For example, in the ions such as CrO<sub>4</sub><sup>2-</sup>, MnO<sub>4</sub><sup>-</sup>, the bonds formed are covalent.
- (vi) The relative stability of various oxidation states of a given element can be explained on the basis of stability of  $d^0$ ,  $d^5$  and  $d^{10}$  configurations. For example,

 $Ti^{4+}$   $(3d^04s^0)$  is more stable than  $Ti^{3+}$   $(3d^14s^0)$ ;  $Mn^{2+}(3d^54s^0)$  is more stable than  $Mn^{3+}$   $(3d^44s^0)$ ;  $Fe^{3+}$   $(3d^54s^0)$  is more stable than  $Fe^{2+}(3d^64s^0)$ , etc. The relative stabilities of various oxidation states of a given element can also be explained on the basis of standard electrode potential data. For example, in case of copper we have

$$Cu^+(aq) + e^- \longrightarrow Cu(s); \quad E^o = 0.52 \text{ V}$$
  
 $Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s); \quad E^o_{red} = 0.34 \text{ V}$ 

Thus, Cu<sup>+</sup> is reduced easily and hence is less stable than Cu<sup>2+</sup>.

- (vii) In a group of d-block elements, the higher oxidation states are more stable for heavier elements. For example, in group 6, Mo(vi) and W(vi) are more stable than Cr(vi). For example, dichromate having Cr(vi) is a strong oxidising agent in acidic medium while MoO<sub>3</sub> and WO<sub>3</sub> are stable oxides.
- (viii) In transition elements the successive oxidation states differ by unity.

A substance appears coloured because it absorbs light atspecific wavelengths in the visible part of the electromagnetic spectrum (4000 to 7000Å) and transmits or reflects the rest of the wavelengths. Each wavelength of visible light represents a different colour. White light is a combination of all colours. The table given shows the relationship of wavelength absorbed to the observed colour.

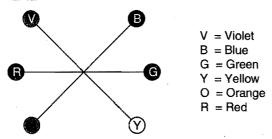

Wavelength absorbed (Å)	Colour observed
4000 (Violet)	Greenish yellow
4500 (Blue)	Yellow
· 4900 (Blue-green)	Red
5700 (Yellowish green)	Violet
5800 (Yellow)	Dark blue
6000 (Orange)	Blue
6500 (Red)	Blue-green

Most of the compounds of transition metals are coloured in the solid or in solution states. The colour of transition metal ions arises from the excitation of electrons from the d-orbitals of lower energy to the d-orbitals of higher energy. The energy required for d-d electron excitations is available in the visible range. It is for this reason that transition metal ions have the property to absorb certain radiations from the visible region and exhibit the complementary colour. The colours and outer electronic configurations of important ions of the elements of first transition series are tabulated ahead:

COLOURS AND MAGNETIC MOMENTS OF IONS OF	
THE FIRST TRANSITION SERIES	

Ion	Outer configuration	Number of unpaired electrons	Colour of the	Magnetic moment (B.M.)
Sc <sup>3+</sup> Ti <sup>4+</sup> Ti <sup>3+</sup> V <sup>3+</sup> Cr <sup>3+</sup> Mn <sup>3+</sup>	$3d^0$ $3d^0$	0	Colourless	0
Ti <sup>4+</sup>	$3d^0$	0	Colourless	0
Ti <sup>3+</sup>	$3d^1$	1	Purple	1.75
$V^{3+}$	$3d^{2}$ $3d^{3}$ $3d^{4}$ $3d^{5}$ $3d^{6}$	2	Green	2.76
Cr <sup>3+</sup>	$3d^3$	3	Violet .	3.86
Mn <sup>3+</sup>	$3d^4$	4	Violet	5.0
Mn <sup>2+</sup> Fe <sup>2+</sup> Fe <sup>3+</sup> Co <sup>2+</sup>	$3d^5$	5	Light pink	5.96
Fe <sup>2+</sup>	$3d^6$	4	Green	5.10
Fe <sup>3+</sup>	$3d^5$	5	Yellow	5.96
Co <sup>2+</sup>	$3d^7$	3	Pink	4.4 - 5.2
Ni <sup>2+</sup>	$3d^8$	2	Green	2.9 - 3.4
Cu <sup>2+</sup>	$3d^9$ $3d^{10}$	1	Blue	1.8 – 2.2
Cu <sup>+</sup>	$3d^{10}$	0	Colourless	0
$Zn^{2+}$	$3d^{10}$	. 0	Colourless	0

Complementary colours can be identified using Munshel colour wheel.

Opposite colours are complementary.

The transition metal ions which have completely filled d-orbitals  $(3d^{10}, 4d^{10} \text{ or } 5d^{10})$  such as  $Zn^{2+}$ ,  $Cd^{2+}$ ,  $Hg^{2+}$ ,  $Cu^{+}$ ,  $Ag^{+}$  and  $Au^{+}$  ions are colourless as the excitation of electron or electrons is not possible within d-orbitals. The transition metal ions which have completely empty d-orbitals such as  $Sc^{3+}$ ,  $Ti^{4+}$ , etc., are also colourless.

[Note: In the oxysalts of transition elements like KMnO<sub>4</sub>, K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, there are no unpaired electrons at the central atom but they are deep in colour. The colour of these compounds is due to charge transfer spectrum.

Observe the colour of following compounds of silver

	AgCl	AgBr	AgI	Ag <sub>2</sub> S
Colour	White	Pale Yellow	Yellow	Black
% Ionic character $A\sigma^{+} = 4d^{10}5s^{0}$	80%	24%	15%	4%

There is no unpaired electron with Ag<sup>+</sup>. Thus, colour of these compounds can be explained on the basis of percentage ionic character.

If the ionic character of these ionic compounds is less than 20% then the compound will be coloured.]

1 B.M.=
$$\frac{eh}{4\pi mc}$$
 B.M. = Bohr-magneton

#### 10. Magnetic Properties

Majority of substances show magnetic nature. These are either **paramagnetic** or **diamagnetic**. A paramagnetic substance is one which is weakly attracted into a magnetic field and a diamagnetic substance is one which is repelled by a magnetic field. The paramagnetic behaviour arises due to the presence of one or more singly occupied atomic orbitals, while diamagnetic behaviour is due to presence of paired electrons in the atomic orbitals.

Most of the compounds of transition elements are paramagnetic in nature as unpaired electrons in d-subshell are present. The magnetic character is expressed in terms of magnetic moment. The magnetic moments arise only from the spin of electrons. The effective total magnetic moment,  $\mu_{eff}$ , is given by the expression.\*

$$\mu_{\text{eff}} = \sqrt{n(n+2)}$$
 B.M.

where n is the number of unpaired electrons. Larger the number of unpaired electrons in a substance, the greater is its magnetic moment in Bohr-magneton and larger shall be its paramagnetism. The magnetic moments of some important ions of the elements of first transition series are given in the table.

It is evident from the values that the magnetic moments or paramagnetic behaviour increases as the number of unpaired electrons increases from 1 to 5. After  $d^5$  configuration, there is decrease in magnetic moment as the number of unpaired electrons decreases.

In the case of iron, cobalt and nickel the unpaired electron spins are much more pronounced. As a result, these elements are much more paramagnetic than the rest of the elements.

These elements are termed ferromagnetic and can be magnetised.

#### 11. Tendency to form Complexes

d-block elements have a marked ability to form complex compounds. This ability is on account of following three reasons:

(i) Small size (ii) high nuclear charge (iii) a number of vacant orbitals of equivalent energy where, the electrons donated by ligands can be accommodated. Ligands are species with lone pair of electrons which they can readily donate. These species can be neutral molecules such as NH<sub>3</sub>, H<sub>2</sub>O, NO, CO, etc., or ions such as F<sup>-</sup>, Cl<sup>-</sup>, CN<sup>-</sup>, etc.

The number of attachment with ligands are usually either four or six, *i.e.*, the coordination number of metal ion is usually four or six. The compounds containing complex ions are termed as coordination compounds. Na<sub>3</sub>[Fe(CN)<sub>6</sub>], [Cu(NH<sub>3</sub>)<sub>4</sub>]SO<sub>4</sub>, [Cr(NH<sub>3</sub>)<sub>6</sub>]Cl<sub>3</sub> and Ni(CO)<sub>4</sub> are some of the examples of

<sup>\*</sup> This expression is applicable mainly to 3d elements.

 $e = \text{Charge of electron}; \ h = \text{Planck constant}; \ m = \text{Mass of electron}; \ c = \text{Velocity of light}$ 

coordination compounds. Coordination compounds are discussed in detail in chapter 15.

#### 12. Formation of Interstitial Compounds

Small non-metallic atoms such as H, B, C, N, etc., are able to occupy interstitial spaces of the lattices of the d-block elements to form combinations which are termed interstitial compounds. These are non-stoichiometric in nature and do not follow the common rules of valency. The bonds present are neither typically ionic nor covalent. The formulae do not correspond to any normal oxidation state of the metal.

Some of the characteristics of interstitial compounds are:

- (i) The interstitial compounds have similar chemical properties as the parent metals but differ appreciably in their physical properties such as density, conductivity, hardness, etc.
- (ii) As a result of filling up of the interstitial spaces, the metals become rigid and hard. Steel is quite hard as it is interstitial compound of Fe and C. Some of the borides are as hard as diamond.
- (iii) Interstitial compounds possess high melting points which are higher than those of pure metals.

#### 3 13. Catalytic Properties

Many of the *d*-block elements and their compounds act as catalysts in various reactions. Some common examples are:

- (i) Pt—used as a catalyst in the manufacture of H<sub>2</sub>SO<sub>4</sub>.
- (ii) Fe—used as a catalyst in the manufacture of NH<sub>3</sub> by Haber process. A small amount of molybdenum is added as a promoter.
- (iii) Ni—used as a catalyst in the hydrogenation of oils.
- (iv) V<sub>2</sub>O<sub>5</sub>—used as a catalyst for the oxidation of SO<sub>2</sub> into SO<sub>3</sub> for the manufacture of H<sub>2</sub>SO<sub>4</sub> in the contact process.
- (v) MnO<sub>2</sub>—used as a catalyst in the decomposition of KClO<sub>3</sub> for preparation of oxygen.
- (vi) Cobalt salts catalyse the decomposition of bleaching powder.

Catalytic property is probably due to the utilisation of (n-1)d-orbitals or formation of interstitial compounds.

#### 14. Alloy Formation

Transition metals form a large number of alloys. Since d-block elements are quite similar in atomic size, the atoms of one metal can substitute the atoms of other metal in its crystal lattice. Thus, on cooling a mixture solution of two or more transition metals, smooth solid alloys are formed.

Alloys containing mercury as one of the constituent elements are called **amalgams**. The purpose of making alloys is to develop some useful properties which are absent in the constituent elements.

#### **15. Some Important Compounds**

The transition metals combine with a number of non-metals such as oxygen, nitrogen, carbon, halogens, sulphur and phosphorus, etc., to form useful binary compounds. General trends in oxides, halides and sulphides are discussed.

(a) Oxides: The elements of first transition series form a number of oxides having general formulae MO,  $M_2O_3$ ,  $M_3O_4$ ,  $MO_2$ ,  $M_2O_5$ ,  $MO_3$ . The oxides are generally formed when the metals are strongly heated at high temperature in the atmosphere of oxygen. These oxides exhibit acidic, basic and amphoteric behaviour. The important and common oxides of the elements of first transition series are listed in the following table:

# OXIDES OF THE METALS OF FIRST TRANSITION SERIES

Sc		$Sc_2O_3(b)$			
Ti	TiO(b)	$Ti_2O_3(b)$	$TiO_2(c)$	,	
V	VO(b)	$V_2O_3(b)$	VO <sub>2</sub> (c)	$V_2O_5(a)$	con a menimbanden I dimerciden an sambilitation and discover anno belle "
Cr	CrO(b)	Cr <sub>2</sub> O <sub>3</sub> (c)	CrO <sub>2</sub> (c)		CrO <sub>3</sub> (a)
Mn	MnO(b)	$Mn_2O_3(b)$	MnO <sub>2</sub> (c)	Mn <sub>3</sub> O <sub>4</sub> (c)	$[MnO_3(a)]Mn_2O_7(a)$
Fe	FeO(b)	$Fe_2O_3(b)$		Fe <sub>3</sub> O <sub>4</sub> (b)	
Co	CoO(b)	$[\mathbf{Co_2O_3^h(b)}]$	[[CoO <sup>h</sup> 2]	· · · ·	
Ni	NiO(b)	$[Ni_2O_3^h(b)]$	$NiO_2^h$	Mixed	
Cu	CuO(b)		•		
Zn	ZnO(b)				

where a = acidic; b = basic; c = amphoteric; h = hydrated

[Note: Stable oxides have been indicated by bold letters. Unstable are in parentheses.]

- (i) The oxides in lower oxidation states are basic in nature.
- (ii) The oxides in intermediate oxidation states are amphoteric.
  - (iii) The oxides of higher oxidation states are acidic in nature. **Examples:**

#### Oxides of chromium:

#### Oxides of manganese:

It can also be said that if a metal forms a number of oxides, the acidic nature of the oxides increases as the percentage of oxygen increases.

(iv) The basic and amphoteric oxides generally dissolve in non-oxidising acids like HCl to form hexaaquo ions,  $[M(H_2O)_6]^{n+}$ .

- (v) Some of the oxides dissolve in acids or bases to form oxometallic salts such as chromates, dichromates, permanganates, etc.
- (b) Halides: Transition metals combine with halogens at high temperatures to form compounds called halides. On account of high activation energies of these reactions, high temperature is usually needed to start the reaction, but once the reaction starts, the heat of reaction is sufficient to maintain the continuity of the reaction (Reactions are exothermic in nature). The order of the reactivity of halogens is:

Metals in higher oxidation states only form fluorides as it is the most electronegative and reactive element. The following are some of the general characteristics of halides.

(i) Fluorides are mainly ionic in nature. The chlorides, bromides and iodides have ionic as well as covalent character. The covalent character increases as atomic mass of the halogen increases. For example, CuF<sub>2</sub> is ionic compound while CuCl<sub>2</sub> and CuBr<sub>2</sub> are covalent forming infinite chains. The coordination number of the copper in these compounds is six. The structure of CuCl<sub>2</sub> is given below:

(ii) Halides of metals in higher oxidation states are relatively unstable and undergo hydrolysis very easily.

$$TiCl_4 + 2H_2O \longrightarrow TiO_2 + 4HCl$$

The solutions of several halides are acidic in nature due to hydrolysis. These solutions can be stabilised by addition of acids in order to prevent hydrolysis.

$$FeCl_3 + 3H_2O \implies Fe(OH)_3 + 3HCl$$
  
 $CuCl_2 + 2H_2O \implies Cu(OH)_2 + 2HCl$ 

(c) Sulphides: Sulphides of transition metals can be formed either by direct combination of the metals with sulphur or by action of H<sub>2</sub>S or Na<sub>2</sub>S on the salts of these metals.

Fe + S 
$$\longrightarrow$$
 FeS  
CuSO<sub>4</sub> + H<sub>2</sub>S  $\longrightarrow$  CuS + H<sub>2</sub>SO<sub>4</sub>  
2AgNO<sub>3</sub> + Na<sub>2</sub>S  $\longrightarrow$  Ag<sub>2</sub>S + 2NaNO<sub>3</sub>

Sulphides of transition metals are coloured usually black and are insoluble in water.

## 14.4 CHEMISTRY OF CHROMIUM

Chromium belongs to group 6 (VI B) of the extended form of periodic table. The other members of the group are molybdenum (Mo) and tungsten (W). The most abundant element of this group is chromium. The most important ore of chromium is **chromite** or **chrome-iron stone**, FeO·Cr<sub>2</sub>O<sub>3</sub>.

The concentrated ore is mixed with excess of sodium carbonate and roasted in a reverberatory furnace in a free supply of air.  $Cr_2O_3$  present in the ore is converted into sodium chromate.

The roasted mass is extracted with water when Na<sub>2</sub>CrO<sub>4</sub> goes into solution leaving behind insoluble Fe<sub>2</sub>O<sub>3</sub> and unconverted ore. The solution is treated with calculated amount of sulphuric acid to convert sodium chromate into dichromate.

$$2Na_2CrO_4+H_2SO_4 \longrightarrow Na_2Cr_2O_7+Na_2SO_4+H_2O_7$$

The solution is concentrated when less soluble Na<sub>2</sub>SO<sub>4</sub> crystallises out. The solution is further concentrated when crystals of Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> are obtained. Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is heated with carbon and the chromite thus formed is extracted with water when Cr<sub>2</sub>O<sub>3</sub> is precipitated.

$$Na_2Cr_2O_7 + 3C \longrightarrow Na_2Cr_2O_4 + 3CO$$
  
Sodium chromite

$$Na_2Cr_2O_4 + H_2O \longrightarrow 2NaOH + Cr_2O_3$$

Reduction of Cr<sub>2</sub>O<sub>3</sub> is done by Goldsmith alumino-thermic process.

$$Cr_2O_3 + 2Al \longrightarrow 2Cr + Al_2O_3$$

The mixture is taken in the ratio of 3:1 in a refractory crucible and the mixture is ignited with burning magnesium ribbon. The metal obtained is about 92% pure. It is further purified electrolytically using mercury as cathode and chromic chloride solution as electrolyte. The amalgam is finally heated in vacuum to get 99.7% pure metal.

**Ferrochrome:** An alloy of Cr and Fe containing about 75% Cr is obtained when chromite ore is reduced with carbon in an electric furnace.

$$FeO \cdot Cr_2O_3 + 4C \longrightarrow Fe + 2Cr + 4CO$$
Alloy

Ferrochrome is extensively used for alloying with iron to make special steels.

#### Uses

- (i) Chromium is used in making alloys such as chrome steels, stainless steel (18% Cr) and nichrome (Ni 60%, Fe 25%, Cr 15%).
- (ii) It is extensively used for plating metals because it is very resistant to corrosion.
  - (iii) Its compounds find wide applications.

The outer electronic configuration of chromium is  $3d^54s^1$ . It exhibits a large number of oxidation states varying from O to +6. The stable and important oxidation states of Cr are +2, +3 and +6. Chromium (II) compounds are reducing agents as they are readily converted into chromium (III) compounds even by the oxygen of the air. +3 oxidation state is highly stable in acid solutions but it gets oxidised readily to +6 oxidation

state in alkali solutions. Chromium compounds in +6 oxidation states are strong oxidising agents.

#### 14.5 POTASSIUM DICHROMATE, K2Cr2O7

It is the most important compound of Cr (VI). It is manufactured from chromite ore. Chromite ore is first converted into sodium dichromate as described in section 14.4. The hot saturated solution of sodium dichromate is mixed with KCl. Sodium chloride precipitates out from the hot solution which is filtered off. On cooling the mother liquor, crystals of potassium dichromate separate out.

$$Na_2Cr_2O_7 + 2KCl \longrightarrow K_2Cr_2O_7 + 2NaCl$$

#### Properties

It is orange-red coloured crystalline compound. It is moderately soluble in cold water but freely soluble in hot water. It melts at 398°C. On heating strongly, it decomposes liberating oxygen.

$$2K_2Cr_2O_7 \longrightarrow 2K_2CrO_4 + Cr_2O_3 + \frac{3}{2}O_2$$

On heating with alkalies, it is converted to chromate, *i.e.*, the colour changes from orange to yellow. On acidifying, yellow colour again changes to orange.

$$\begin{array}{c} K_2Cr_2O_7 + 2KOH \longrightarrow 2K_2CrO_4 + H_2O \\ Cr_2O_7^{2-} + 2OH^- \longrightarrow 2CrO_4^{2-} + H_2O \\ \text{Orange} \qquad \qquad \text{Yellow} \\ 2CrO_4^{2-} + 2H^+ \longrightarrow Cr_2O_7^{2-} + H_2O \\ \text{Yellow} \qquad \qquad \text{Orange} \end{array}$$

In alkaline solution, chromate ions are present while in acidic solution, dichromate ions are present. Both the ions are in equilibrium at pH = 4.

$$Cr_2O_7^{2-} + H_2O \rightleftharpoons 2CrO_4^{2-} + 2H^+$$

Potassium dichromate reacts with hydrochloric acid and evolves chlorine.

$$K_2Cr_2O_7 + 14HCl \longrightarrow 2KCl + 2CrCl_3 + 7H_2O + 3Cl_2$$

It acts as a powerful exidising agent in acidic medium (dilute  $H_2SO_4$ ).

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$$

Cold concentrated solution of  $K_2Cr_2O_7$ , on treatment with concentrated  $H_2SO_4$  forms chromic anhydride (CrO<sub>3</sub>).

The oxidation state of Cr changes from +6 to +3.

The potential equation in terms of available oxygen can be given as:

$$\begin{array}{c} K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O] \\ \text{1 mole} \\ \end{array}$$

Thus, the equivalent mass of  $K_2Cr_2O_7$  in acidic medium is  $\frac{\text{Mol. mass}}{6}$ , i.e.,  $\frac{294}{6} = 49$ .

Some typical oxidation reactions are given below:

(i) Iodine is liberated from potassium iodide.

$$K_2Cr_2O_7+4H_2SO_4 \longrightarrow K_2SO_4+Cr_2(SO_4)_3+4H_2O+3[O]$$
  
 $[2KI + H_2SO_4 + [O] \longrightarrow K_2SO_4 + I_2 + H_2O] \times 3$ 

$$K_2Cr_2O_7+6KI+7H_2SO_4 \longrightarrow 4K_2SO_4+Cr_2(SO_4)_3+7H_2O+3I_2$$

The equation in terms of electron method may also be written as

$$Cr_2O_7^{2-} + 14H^+ + 6e^- \longrightarrow 2Cr^{3+} + 7H_2O$$
  
 $6I^- \longrightarrow 3I_2 + 6e^-$   
 $Cr_2O_7^{2-} + 14H^+ + 6I^- \longrightarrow 2Cr^{3+} + 3I_2 + 7H_2O$ 

(ii) Ferrous salts are oxidised to ferric salts.

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$
  
 $[2FeSO_4 + H_2SO_4 + [O] \longrightarrow Fe_2(SO_4)_3 + H_2O] \times 3$ 

$$K_2Cr_2O_7 + 6FeSO_4 + 7H_2SO_4 \longrightarrow 3Fe_2(SO_4)_3 + Cr_2(SO_4)_3 + 7H_2O + K_2SO_4$$

or 
$$6Fe^{2+} + Cr_2O_7^{2-} + 14H^+ \longrightarrow 6Fe^{3+} + 2Cr^{3+} + 7H_2O$$

(iii) Sulphites are oxidised to sulphates.

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$
  
 $[Na_2SO_3 + [O] \longrightarrow Na_2SO_4] \times 3$ 

$$\begin{array}{c} K_2Cr_2O_7 + 3Na_2SO_3 + 4H_2SO_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + K_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 \longrightarrow 3Na_2SO_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 + \\ Cr_2(SO_4)_3 + 4H_2O_4 + \\ Cr_2(SO_4)_4 + Cr_2(SO_4)_5 + \\ Cr_2(SO_4)_5 + Cr_2(SO_4)_5$$

or 
$$Cr_2O_7^{2-} + 3SO_3^{2-} + 8H^+ \longrightarrow 3SO_4^{2-} + 2Cr^{3+} + 4H_2O$$

(iv) H<sub>2</sub>S is oxidised to sulphur.

$$K_2Cr_2O_7 + 4H_2SO_4 + 3H_2S \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 3S$$
  
or  $Cr_2O_7^{2-} + 3H_2S + 8H^+ \longrightarrow 2Cr^{3+} + 7H_2O + 3S$ 

(v) SO<sub>2</sub> is oxidised to H<sub>2</sub>SO<sub>4</sub>.

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$
  
 $[SO_2 + [O] + H_2O \longrightarrow H_2SO_4] \times 3$ 

$$K_2Cr_2O_7 + H_2SO_4 + 3SO_2 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O$$
  
or  $Cr_2O_7^{2-} + 3SO_2 + 2H^+ \longrightarrow 2Cr^{3+} + 3SO_4^{2-} + H_2O$ 

When the solution is evaporated, chrome-alum is obtained. (vi) It oxidises ethyl alcohol to acetaldehyde and acetaldehyde to acetic acid.

$$\begin{array}{c} C_2H_5OH \xrightarrow{[O]} CH_3CHO \xrightarrow{[O]} CH_3COOH \\ \text{Ethyl alcohol} & \text{Acetaldehyde} \end{array}$$

It also oxidises nitrites to nitrates, arsenites to arsenates, thiosulphate to sulphate and sulphur  $(S_2O_3^{2-} + O \longrightarrow SO_4^{2-} + S)$ , HBr to Br<sub>2</sub>, HI to I<sub>2</sub>, etc.

$$Cr_2O_7^{2-} + 8H^+ + 3NO_2^- \longrightarrow 2Cr^{3+} + 3NO_3^- + 4H_2O$$
  
 $Cr_2O_7^{2-} + 8H^+ + 3S_2O_3^{2-} \longrightarrow 2Cr^{3+} + 3SO_4^{2-} + 3S + 4H_2O$   
 $K_2Cr_2O_7 + 14HBr \longrightarrow 2KBr + 2CrBr_3 + 7H_2O + 3Br_2$   
 $K_2Cr_2O_7 + 14HI \longrightarrow 2KI + 2CrI_3 + 7H_2O + 3I_2$ 

(vii) Chromyl chloride test: This is a test of chloride. When a mixture of a metal chloride and potassium dichromate is heated with conc.  $H_2SO_4$ , orange-red vapours of chromyl chloride are evolved.

$$K_2Cr_2O_7 + 2H_2SO_4 \longrightarrow 2KHSO_4 + 2CrO_3 + H_2O$$
  
 $[NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl] \times 4$   
 $[CrO_3 + 2HCl \longrightarrow CrO_2Cl_2 + H_2O] \times 2$ 

$$\begin{array}{c} K_2Cr_2O_7 + 6H_2SO_4 + 4NaCl \longrightarrow 2KHSO_4 + 4NaHSO_4 \\ + 2CrO_2Cl_2 + 3H_2O \\ \hline \\ Chromyl \ chloride \end{array}$$

When chromyl chloride vapours are passed through NaOH solution, yellow coloured solution is obtained.

$$4NaOH + CrO_2Cl_2 \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O$$
  
Yellow soln.

The yellow coloured solution on acidification with acetic acid followed by addition of lead acetate gives thick yellow precipitate of lead chromate.

$$Na_2CrO_4 + (CH_3COO)_2Pb \longrightarrow PbCrO_4 + 2CH_3COONa$$
  
Lead chromate  
(yellow ppt.)

[Note: This test is not positive with the chlorides of Hg, Ag, Pb and Sn.]

(viii) Acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution reacts with hydrogen peroxide to give a deep blue solution due to formation of CrO<sub>5</sub>. It is unstable and blue colour fades away gradually due to formation of chromic sulphate.

$$K_2Cr_2O_7 + H_2SO_4 \longrightarrow K_2SO_4 + H_2Cr_2O_7$$
 $(conc.)$ 
 $[H_2O_2 \longrightarrow H_2O + O] \times 4$ 
 $H_2Cr_2O_7 + 4[O] \longrightarrow 2CrO_5 + H_2O$ 

$$K_2Cr_2O_7 + H_2SO_4 + 4H_2O_2 \longrightarrow 2CrO_5 + K_2SO_4 + 5H_2O_4$$
 $4CrO_5 + 6H_2SO_4 \longrightarrow 2Cr_2(SO_4)_3 + 6H_2O + 7O_2$ 
 $CrO_4$  (perovide of abromium) is represented as

CrO<sub>5</sub> (peroxide of chromium) is represented as

#### ■ Some Miscellaneous Reactions

(a) Powdered  $K_2Cr_2O_7$  on treatment with warm concentrated HCl forms petigot's salt.

K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> + 2HCl 
$$\longrightarrow$$
 2KCrO<sub>3</sub>Cl + H<sub>2</sub>O

Potassium
chlorochromate
(Petigot's salt)

(b) With  $K_2CO_3$ ,  $K_2Cr_2O_7$  forms potassium chromate.  $K_2Cr_2O_7 + K_2CO_3 \longrightarrow 2K_2CrO_4 + CO_2$  (c) Potassium dichromate on heating with carbon is reduced to potassium chromite which on treatment with water gives chromium sesquioxide.

$$K_2Cr_2O_7 + 3C \longrightarrow K_2Cr_2O_4 + 3CO$$
  
 $K_2Cr_2O_4 + H_2O \longrightarrow 2KOH + Cr_2O_3$ 

(d) When potassium dichromate and ammonium chloride mixture is heated, nitrogen is evolved.

$$K_2Cr_2O_7 + 2NH_4Cl \xrightarrow{Heat} 2KCl + Cr_2O_3 + N_2 + 4H_2O$$

(e) K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, on fusion with K<sub>4</sub>Fe(CN)<sub>6</sub>, potassium cyanate is formed.

$$\frac{2K_2Cr_2O_7 + 2K_4Fe(CN)_6 \longrightarrow 6KCNO + 2Cr_2O_3 + 2K_2O}{+ K_2Fe[Fe(CN)_6]}$$

Structure of chromate and dichromate ions: The chromate ion has a tetrahedral structure. In dichromate, two tetrahedral sharing one oxygen atom at one corner are present.

#### Uses

Potassium dichromate is used (i) as a volumetric reagent in the estimation of reducing agents such as oxalic acid, ferrous ions, iodide ions, etc. It is used as a primary standard. (ii) for the preparation of several chromium compounds such as chrome alum, chrome yellow, chrome red, zinc yellow, etc. (iii) in dyeing, chrome tanning, calico printing, photography, etc. (iv) chromic acid as a cleansing agent for glassware. (v) in organic chemistry as an oxidising agent (vi) as laboratory reagent. (vii) Acidified solution of  $K_2Cr_2O_7$  provides a test to find out whether a person is drunken or not. A person is asked to breathe into a solution of  $K_2Cr_2O_7$  (acidified). If the colour of the solution turns green, it confirms that the person is in drunken state.

#### 14.6 CHEMISTRY OF MANGANESE

Manganese is a member of group 7 (VIIB). The other members of the group are technetium (Tc) and rhenium (Re). Of these elements, only manganese is important. It is twelfth most abundant element by mass in earth's crust. Technetium is not

found in nature and was the first man-made element. Rhenium is a very rare element. The important ores of manganese are:

- (i) Pyrolusite, MnO<sub>2</sub>
- (ii) Braunite, Mn<sub>2</sub>O<sub>3</sub> and
- (iii) Hausmannite, Mn<sub>3</sub>O<sub>4</sub>.

Manganese is obtained from its oxide ore generally pyrolusite or hausmannite by reduction with carbon or aluminium.

Since MnO<sub>2</sub> gives an explosive reaction with aluminium, it is first converted into manganomanganic oxide, Mn<sub>3</sub>O<sub>4</sub>, by heating to redness. This is then reduced with aluminium in fire-clay crucible embedded in sand.

$$3MnO_2 \longrightarrow Mn_3O_4 + O_2$$
  
 $3Mn_3O_4 + 8Al \longrightarrow 9Mn + 4Al_2O_3$ 

Manganese is purified by distillation in vacuum.

The chief use of manganese is in steel production. 95% of the manganese ores mined are used in steel industry to produce alloys. The mixed oxides of iron and manganese are reduced by heating in a blast furnace along with carbon. Two important alloys are *ferromanganese* (80% Mn and 20% Fe) and spiegeleisen (20 - 30% Mn, 5% C and rest Fe).

The outer electronic configuration of manganese is  $3d^54s^2$ . It exhibits a large number of oxidation states varying from 0 to +7. The zero oxidation state is observed in carbonyls. The +2 state is the most stable and most common. Manganese exhibits +3, +4, +6 and +7 oxidation states. In +7 state the permanganates are strong oxidising agent. +4 and +7 states are also stable. Manganese forms a number of oxides. The basic nature decreases while acidic nature increases as the oxidation state increases.

Manganous Manganic Manganites Manganates Permangasalts salts nates

Manganese also forms a mixed oxide, Mn<sub>3</sub>O<sub>4</sub>, which is a combination of MnO and Mn<sub>2</sub>O<sub>3</sub>. It is known as manganomanganic oxide.

# 14.7 POTASSIUM PERMANGANATE, KMnO<sub>4</sub>

This is the most important and well known salt of permanganic acid. It is prepared from the pyrolusite ore. It is prepared by fusing pyrolusite ore either with KOH or K<sub>2</sub>CO<sub>3</sub> in presence of atmospheric oxygen or any other oxidising agent such as KNO<sub>3</sub>. The mass turns green with the formation of potassium manganate, K<sub>2</sub>MnO<sub>4</sub>.

$$2MnO_2 + 4KOH + O_2 \longrightarrow 2K_2MnO_4 + 2H_2O$$
  
 $2MnO_2 + 2K_2CO_3 + O_2 \longrightarrow 2K_2MnO_4 + 2CO_2$ 

The fused mass is extracted with water. The solution is now treated with a current of chlorine or ozone or carbon dioxide to convert manganate into permanganate.

$$2K_2MnO_4 + Cl_2 \longrightarrow 2KMnO_4 + 2KCl$$

$$2K_2MnO_4 + H_2O + O_3 \longrightarrow 2KMnO_4 + 2KOH + O_2$$
$$3K_2MnO_4 + 2CO_2 \longrightarrow 2KMnO_4 + MnO_2 + 2K_2CO_3$$

Now-a-days, the conversion is done electrolytically.

It is electrolysed between iron cathode and nickel anode. Dilute alkali solution is taken in the cathodic compartment and potassium manganate solution is taken in the anodic compartment. Both the compartments are separated by a diaphragm. On passing current, the oxygen evolved at anode oxidises manganate into permanganate.

At anode:

$$2K_{2}MnO_{4} + H_{2}O + O \longrightarrow 2KMnO_{4} + 2KOH$$

$$MnO_{4}^{2-} \longrightarrow MnO_{4}^{-} + e$$
Green Purple

At cathode:

$$2H^+ + 2e \longrightarrow H_2$$

The anodic solution is concentrated under controlled conditions. when crystals of potassium permanganate are obtained.

## Properties

It is purple coloured crystalline compound. It is fairly soluble in water. When heated alone or with an alkali, it decomposes evolving oxygen.

$$2KMnO_4 \longrightarrow K_2MnO_4 + MnO_2 + O_2$$
  
 $4KMnO_4 + 4KOH \longrightarrow 4K_2MnO_4 + 2H_2O + O_2$ 

On treatment with conc.  $H_2SO_4$ , it forms manganese heptoxide via permanganyl sulphate which decomposes explosively on heating.

$$\begin{array}{c} 2KMnO_4 + 3H_2SO_4 \longrightarrow 2KHSO_4 + (MnO_3)_2SO_4 + 2H_2O \\ (MnO_3)_2SO_4 + H_2O \longrightarrow Mn_2O_7 + H_2SO_4 \\ Mn_2O_7 \longrightarrow 2MnO_2 + \frac{3}{2}O_2 \end{array}$$

Potassium permanganate is a powerful oxidising agent. A mixture of sulphur, charcoal and KMnO<sub>4</sub> forms an explosive powder. A mixture of oxalic acid and KMnO<sub>4</sub> catches fire spontaneous after a few seconds. The same thing happens when glycerine is poured over powdered KMnO<sub>4</sub>.

Potassium permanganate acts as an oxidising agent in alkaline, neutral or acidic solutions.

(a) In alkaline solution: KMnO<sub>4</sub> is first reduced to manganate and then to insoluble manganese dioxide. Colour changes first from purple to green and finally becomes colourless. However, brownish precipitate is formed.

$$\begin{array}{c} 2KMnO_4 + 2KOH \longrightarrow 2K_2MnO_4 + H_2O + O \\ 2K_2MnO_4 + 2H_2O \longrightarrow 2MnO_2 + 4KOH + 2O \\ \hline 2KMnO_4 + H_2O \xrightarrow{Alkaline} 2MnO_2 + 2KOH + 3[O] \\ or 2MnO_4 + H_2O \longrightarrow 2MnO_2 + 2OH + 3[O] \end{array}$$

(b) In neutral solution:  $MnO_2$  is formed. Brownish ppt. is present.

$$2KMnO_4 + H_2O \longrightarrow 2MnO_2 + 2KOH + 3[O]$$
or 
$$2MnO_4^- + H_2O \longrightarrow 2MnO_2 + 2OH^- + 3[O]$$
or 
$$MnO_4^- + 2H_2O + 3e^- \longrightarrow MnO_2 + 4OH^-$$

(c) In acidic solution (in presence of dilute H<sub>2</sub>SO<sub>4</sub>): Manganous sulphate is formed. The solution becomes colourless.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$
or 
$$2MnO_4^- + 6H^+ \longrightarrow 2Mn^{2+} + 3H_2O + 5[O]$$
or 
$$MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$$

This medium is used in quantitative (volumetric) estimations. The equivalent mass of  $KMnO_4$  in acidic medium is  $=\frac{Mol.\,mass}{5}$ . The oxidation reactions of acidified  $KMnO_4$  are catalysed by Mn (ii) ion.

The important oxidation reactions are:

(i) Ferrous salts are oxidised to ferric salts.

$$2KMnO_{4} + 3H_{2}SO_{4} \longrightarrow K_{2}SO_{4} + 2MnSO_{4} + 3H_{2}O + 5[O]$$

$$[2FeSO_{4} + H_{2}SO_{4} + [O] \longrightarrow Fe_{2}(SO_{4})_{3} + H_{2}O] \times 5$$

$$2KMnO_{4} + 10FeSO_{4} + 8H_{2}SO_{4} \longrightarrow 5Fe_{2}(SO_{4})_{3} + K_{2}SO_{4}$$

$$+ 2MnSO_{4} + 8H_{2}O$$
or 
$$2MnO_{4} + 10Fe^{2+} + 16H^{+} \longrightarrow 10Fe^{3+} + 2Mn^{2+} + 8H_{2}O$$

(ii) Iodine is evolved from potassium iodide.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$
$$[2KI + H_2SO_4 + [O] \longrightarrow K_2SO_4 + I_2 + H_2O] \times 5$$

$$2KMnO_4+10KI+8H_2SO_4 \longrightarrow 6K_2SO_4+2MnSO_4+5I_2+8H_2O$$

or 
$$2MnO_4^- + 10I^- + 16H^+ \longrightarrow 2Mn^{2+} + 5I_2 + 8H_2O$$

(iii) H<sub>2</sub>S is oxidised to sulphur.

$$2KMnO_4 + 3H_2SO_4 + 5H_2S \longrightarrow K_2SO_4 + 2MnSO_4 + 5S + 8H_2O$$

(iv)  $SO_2$  is oxidised to  $H_2SO_4$ .

$$2KMnO_4 + 5SO_2 + 2H_2O \longrightarrow K_2SO_4 + 2MnSO_4 + 2H_2SO_4$$

(v) Nitrites are oxidised to nitrates.

$$2KMnO_4 + 5KNO_2 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 5KNO_3 + 3H_2O_4$$

(vi) Oxalic acid is oxidised to CO<sub>2</sub>.

$$\begin{array}{c} \text{COOH} \\ \text{5 I} \\ \text{COOH} \end{array} + 2\text{KMnO}_4 + 3\text{H}_2\text{SO}_4 \longrightarrow \begin{array}{c} \text{K}_2\text{SO}_4 + 2\text{MnSO}_4 \\ + 10\text{CO}_2 + 8\text{H}_2\text{O} \end{array}$$

(vii) It oxidises hydrogen halides (HCl, HBr or HI) into  $X_2$ (halogen).

$$2KMnO_4 + 3H_2SO_4 + 10HX \longrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O_7 + 5X_2$$

(viii) Arsenites are oxidised to arsenates.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$
$$[\mathring{N}a_3AsO_3 + [O] \longrightarrow Na_3AsO_4] \times 5$$

$$2KMnO_4 + 3H_2SO_4 + 5Na_3AsO_3 \longrightarrow K_2SO_4 + 2MnSO_4 + 5Na_3AsO_4 + 3H_2O$$

(ix) Hydrogen peroxide is oxidised to  $H_2O$  and  $O_2$ .  $2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$  $[H_2O_2 + [O] \longrightarrow H_2O + O_2] \times 5$ 

$$\begin{array}{c} 2KMnO_4 + 3H_2SO_4 + 5H_2O_2 \longrightarrow K_2SO_4 + 2MnSO_4 \\ & + 8H_2O + 5O_2 \\ or \ 2MnO_4^- + 5H_2O_2 + 6H^+ \longrightarrow 2Mn^{2+} + 8H_2O + 5O_2 \\ (x) \ Ethyl \ alcohol \ is \ oxidised \ to \ acetaldehyde. \\ 2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O] \\ \hline [C_2H_5OH + [O] \longrightarrow CH_3CHO + H_2O] \times 5 \\ \hline 2KMnO_4 + 3H_2SO_4 + 5C_2H_5OH \longrightarrow 5CH_3CHO + K_2SO_4 + 2MnSO_4 + 8H_2O \\ \hline \end{array}$$

#### ■ In Neutral Medium

(i) H<sub>2</sub>S is oxidised to sulphur.

$$2KMnO_4 + H_2O \longrightarrow 2MnO_2 + 2KOH + 3[O]$$
$$[H_2S+[O] \longrightarrow H_2O + S] \times 3$$

$$2KMnO_4 + 3H_2S \longrightarrow 2KOH + 2MnO_2 + 2H_2O + 3S$$

(ii) Manganese sulphate is oxidised to MnO2.

$$2KMnO_4 + H_2O \longrightarrow 2MnO_2 + 2KOH + 3[O]$$

$$[MnSO_4 + H_2O + [O] \longrightarrow MnO_2 + H_2SO_4] \times 3$$

$$2KOH + H_2SO_4 \longrightarrow K_2SO_4 + 2H_2O$$

 $2KMnO_4 + 3MnSO_4 + 2H_2O \longrightarrow K_2SO_4 + 5MnO_2 + 2H_2SO_4$ 

(iii) Sodium thiosulphate is oxidised to sulphate and sulphur.

$$2KMnO_4 + 3Na_2S_2O_3 + H_2O \longrightarrow 2KOH + 2MnO_2 + 3Na_2SO_4 + 3S$$

#### In Alkaline Medium

(i) It oxidises iodide to iodate.

$$\begin{split} 2KMnO_4 + H_2O & \longrightarrow 2KOH + 2MnO_2 + 3[O] \\ KI + 3[O] & \longrightarrow KIO_3 \end{split}$$

$$2KMnO_4 + KI + H_2O \longrightarrow 2KOH + 2MnO_2 + KIO_3$$

(ii) It oxidises ethylene to ethylene glycol.

$$\begin{array}{ccc} CH_2 & CH_2OH \\ \parallel & +H_2O + [O] \longrightarrow | \\ CH_2 & CH_2OH \end{array}$$

In alkaline medium it is called Baeyer's reagent.

**Structure:** In permanganate ion, manganese undergoes  $sp^3$ -hybridisation *i.e.*, tetrahedral configuration results. Four oxygen atoms are present on the four apices of the tetrahedron.

#### Uses

(i) KMnO<sub>4</sub> is used as an oxidising agent in laboratory and industry. In volumetric estimations, the solution is first standardised before use. In volumetric estimations, acidified standardised KMnO<sub>4</sub> solution is used. For maintaining acidic medium only dilute H<sub>2</sub>SO<sub>4</sub> is used. HCl or HNO<sub>3</sub> are not used

because HCl reacts with KMnO<sub>4</sub> and produce Cl<sub>2</sub> gas while HNO<sub>3</sub>, itself reacts as an oxidising agent.

- (ii) Alkaline potassium permanganate is called Baeyer's reagent. This reagent is used in organic chemistry for the test of unsaturation. KMnO<sub>4</sub> is used in the manufacture of saccharin, benzoic acid, acetaldehyde, etc.
- (iii) KMnO<sub>4</sub> is used in qualitative analysis for detecting halides, sulphites, oxalates, etc.
- (iv) It is widely used as a disinfectant and germicide. A very dilute solution of  $KMnO_4$  is employed for washing wounds and gargling of mouth sores. It is also used for purifying well water.

## 14.8 POSITION OF IRON IN PERIODIC TABLE

Iron belongs to fourth period and VIII group of the extended form of periodic table. VIII group consists of nine elements arranged in three triads. Iron is a member of first triad and other two members of this triad are cobalt and nickel. These three metals are called **ferrous metals** and belong to first transition series (3d series) of the periodic table. The members of second and third triads are collectively known as **platinum metals** or **noble metals**.

Three elements iron, cobalt and nickel possess nearly the same atomic masses and resemble each other closely in their properties. The following discussion shows similarities and gradation in the properties of Fe, Co and Ni.

1. Electronic configuration: Two electrons are present in outermost shell while the penultimate shell is incomplete. The number of electrons on 3d-shell varies from 6 to 8.

Fe	26	2, 8, 14, 2	$1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^6, 4s^2$ $1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^7, 4s^2$	$[Ar](3d^64s^2)$
Co	27	2, 8, 15, 2	$1s^2, 2s^22p^6, 3s^23p^63d^7, 4s^2$	$[Ar](3d^74s^2)$
Ni	28	2, 8, 16, 2	$1s^2, 2s^22p^6, 3s^23p^63d^8, 4s^2$	$[Ar](3d^84s^2)$

Thus, the last differentiating electron is accommodated on 3d-shell. Hence, these elements are called transition elements or d-block elements.

**2. Valency:** They form 'ous' and 'ic' salts showing di- and trivalencies. The stability of  $M^{2+}$  cations increases from Fe<sup>2+</sup> to Ni<sup>2+</sup> ion. Thus, the reducing property of these is in the order Fe<sup>2+</sup>> Co<sup>2+</sup> > Ni<sup>2+</sup>. The removal of a 3d electron from  $M^{2+}$  cations to oxidise them into  $M^{3+}$  cations becomes more and more difficult as we move from Fe<sup>2+</sup> to Ni<sup>2+</sup>. Thus, the tendency to show trivalency decreases sharply from Fe to Ni, *i.e.*, stability of  $M^{3+}$  cations is in the order Fe<sup>3+</sup> > Co<sup>3+</sup> > Ni<sup>3+</sup>. The reason for more stability of Fe<sup>3+</sup> cations is that it has a half-filled 3d-orbitals.

Fe<sup>3+</sup> 2, 8, 8 +5 
$$3d^5$$
  $\uparrow$   $\uparrow$   $\uparrow$   $\uparrow$ 

 $\text{Co}^{3+}$  and  $\text{Ni}^{3+}$  have relatively unstable  $3d^6$  and  $3d^7$  configurations respectively.

Co <sup>3+</sup>	2, 8, 8 +6	$3d^6$	↑↓	1	↑·	<b>↑</b>	<b>↑</b>
Ni <sup>3+</sup>	2, 8, 8 +7	$3d^7$	↑↓	↑↓	1	1	1

Thus, in ous-series, nickelous compounds are most stable while in ic-series, ferric compounds are most stable.

**3. Occurrence:** All the three are relatively abundant. However, iron is more abundant than nickel and cobalt.

## ■ Physical Characteristics

(a) Physical state: These are all greyish white hard metals of high densities. The hardness and density increases from Fe to Ni.

Element	Fe	Co	Ni
Density	7.86	8.9	8.9

(b) Melting and boiling points: They have high melting and boiling points. This shows that covalent bonding is also present involving d electrons between atoms.

Element	. Fe	Co .	Ni
M.pt. (°C)	1536	1495	1453
B.pt. (°C)	3000	2900	2730

- (c) Ionisation energy: Ionisation energies are about the same. Hence, they have same tendency to form ions.
- **(d) Oxidation potential:** The values of oxidation potentials are fairly close to each other. The values are positive and hence they can liberate hydrogen from dilute acids.

Element	Fe	Co	Ni
First I.E. (eV)	7.90	7.86	7.63
Oxidation potential (Volt)	+0.44	+0.28	+0.25

- (e) Magnetic property: All the three elements are ferromagnetic, *i.e.*, these are strongly attracted by a magnet and remain magnetised even after the removal of the magnetic field. The ferromagnetic property decreases from iron to nickel.
- **(f) Catalytic property:** All the three elements are used as catalysts especially in the reactions involving the addition of hydrogen as they occlude or adsorb hydrogen.

# ■ Chemical Properties

The metals are reactive and their reactivity decreases from Fe to Ni.

(a) Action of air: Cobalt and nickel are not affected by air under ordinary conditions. However, iron is affected by moist air. The oxidation of iron into hydrated iron oxide,  $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ , is termed rusting of iron.

When iron is strongly heated in air or oxygen, it forms ferroso-ferric oxide, Fe<sub>3</sub>O<sub>4</sub> (upto 500°C) and Fe<sub>2</sub>O<sub>3</sub> above 500°C. Cobalt when strongly heated also forms Co<sub>3</sub>O<sub>4</sub> while nickel forms NiO.

$$3\text{Fe} + 2\text{O}_2 \longrightarrow \text{Fe}_3\text{O}_4$$
  
 $2\text{Ni} + \text{O}_2 \longrightarrow 2\text{NiO}$ 

**(b)** Action of water: The metals are not affected by water under ordinary conditions but when steam is passed over hot metals, these get oxidised with evolution of hydrogen.

3Fe + 4H<sub>2</sub>O (steam) 
$$\longrightarrow$$
 Fe<sub>3</sub>O<sub>4</sub> + 4H<sub>2</sub>  
Co + H<sub>2</sub>O (steam)  $\longrightarrow$  CoO + H<sub>2</sub>  
Ni + H<sub>2</sub>O (steam)  $\longrightarrow$  NiO + H<sub>2</sub>

(c) Action of acids: Non-oxidising acids (dilute HCl and dilute H<sub>2</sub>SO<sub>4</sub>) evolve hydrogen with iron, cobalt and nickel. Iron reacts readily while cobalt and nickel react slowly.

$$M + 2HCl \longrightarrow MCl_2 + H_2$$
  
 $M + H_2SO_4 \longrightarrow MSO_4 + H_2$ 

All the three metals, dissolve in concentrated sulphuric acid evolving sulphur dioxide.

$$2Fe + 6H2SO4 \longrightarrow Fe2(SO4)3 + 3SO2 + 6H2O$$

$$Co + 2H2SO4 \longrightarrow CoSO4 + SO2 + 2H2O$$

$$Ni + 2H2SO4 \longrightarrow NiSO4 + SO2 + 2H2O$$

These metals dissolve in dilute HNO3 evolving NO.

$$[M + 2HNO_3 \longrightarrow M(NO_3)_2 + 2H] \times 3$$

$$[3H + HNO_3 \longrightarrow NO + 2H_2O] \times 2$$

$$3M + 8HNO_3 \longrightarrow 3M(NO_3)_2 + 2NO + 4H_2O$$

However, with concentrated nitric acid, these metals become passive.

- (d) Action of alkalies: These metals are not affected by
- (e) Action of halogens: These metals directly combine with halogens.

$$\begin{array}{ccc} \text{2Fe} + 3\text{Cl}_2 & \longrightarrow & 2\text{FeCl}_3 \\ & \text{Ferric chloride} \\ \text{Co} + \text{Cl}_2 & \longrightarrow & \text{CoCl}_2 \\ & \text{Cobaltous chloride} \\ \text{Ni} + \text{Cl}_2 & \longrightarrow & \text{NiCl}_2 \\ & \text{Nickelous chloride} \\ \end{array}$$

FeI<sub>3</sub> is unstable and gets reduced to FeI<sub>2</sub>.

$$2\text{FeI}_3 \longrightarrow 2\text{FeI}_2 + \text{I}_2$$

(f) Action of carbon monoxide: All the three metals, combine with carbon monoxide to form volatile carbonyls, viz., Fe(CO)<sub>5</sub>, Co<sub>2</sub>(CO)<sub>8</sub> and Ni(CO)<sub>4</sub>.

$$Ni + 4CO \longrightarrow Ni(CO)_4$$

(g) Isomorphous sulphates: All form isomorphous sulphates.

All these sulphates form double sulphates which are also isomorphous. For example,  $(NH_4)_2SO_4$ ·FeSO<sub>4</sub>·6H<sub>2</sub>O Mohr's salt and  $(NH_4)_2SO_4$ ·NiSO<sub>4</sub>·6H<sub>2</sub>O nickel ammonium sulphate are isomorphous.

(h) Complex compounds: All form complex salts. Some examples are given below:

$$K_4Co(CN)_6$$
  
Potassium cobaltocyanide  $K_3Co(NO_2)_6$   
Potassium cobaltinitrite

Nickel has a coordination number 4 or 6 whereas, iron and cobalt show a coordination number 6 only. Iron does not form amine complex while nickel and cobalt form amine complexes such as [Co(NH<sub>3</sub>)<sub>6</sub>]Cl<sub>3</sub> and [Ni(NH<sub>3</sub>)<sub>4</sub>]Cl<sub>2</sub>.

- (i) Alloy formation: All the three elements have great tendency to form alloys with each other and with other metals.
- (j) Colour of the compounds: The compounds of iron, cobalt and nickel are coloured as 3d-energy shell is incomplete in  $M^{2+}$  and  $M^{3+}$  cations.

Ferrous compounds are usually green while ferric compounds are yellow. The colour of nickel compounds is green while of cobalt compounds is pink.

# 14.9 EXTRACTION OF IRON

Occurrence: Iron is the fourth most abundant element and the second most abundant metal in nature. It occurs in combined state. The main ores of iron are:

- 1. Oxide ores:
- (i) Magnetite, Fe<sub>3</sub>O<sub>4</sub>. It is usually black in colour. It is richest ore of iron and contains upto 70% of the metal.
  - (ii) Haematite, Fe<sub>2</sub>O<sub>3</sub>. It is usually red in colour.
- (iii) Limonite or hydrated ferric oxide, Fe<sub>2</sub>O<sub>3</sub>·3H<sub>2</sub>O. It has yellow, brown or red colour.
  - 2. Carbonate ore:

Siderite or Sepathic iron, FeCO<sub>3</sub>. It is also called clayiron stone due to the presence of excess of clay in it.

- 3. Sulphide ores:
- (i) Iron pyrites, FeS<sub>2</sub>. It is mainly used for the manufacture of sulphur dioxide (sulphuric acid). It is not used for extraction of iron.
- (ii) Chalcopyrites, CuFeS<sub>2</sub>. It is used for the extraction of copper.

Iron ores have been reported at many places especially in England, Sweden, Germany, U.S.A., Russia, Belgium, France, Canada and India. Huge deposits of red haematite are available in India in Mayurbhanj (Orissa), Singhbhum (Jharkhand), Madhya Pradesh and Mysore (Karnataka). On the whole, India possesses about one fourth of the total world reserves of iron ore.

Iron is extracted from its oxide ores especially from the magnetite, haematite and limonite ores. The extraction involves the following steps:

- (i) Concentration of ore: The concentration of ore is done by gravity process. The ore is crushed to small pieces and washed with water to remove silicious impurities. The washed ore is then subjected to electromagnetic separation.
- (ii) Calcination and roasting: The concentrated ore is heated in excess of air. This treatment produces the following results.
  - (a) Moisture and carbon dioxide are removed.

$$2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O} \longrightarrow 2\text{Fe}_2\text{O}_3 + 3\text{H}_2\text{O}$$
  
 $\text{Fe}\text{CO}_3 \longrightarrow \text{Fe}\text{O} + \text{CO}_2$ 

(b) Sulphur, phosphorus, arsenic, etc., are oxidised to their oxides and are, thus, removed as volatile gases.

$$S + O_2 \longrightarrow SO_2$$

$$P_4 + 5O_2 \longrightarrow P_4O_{10}$$

$$4As + 3O_2 \longrightarrow 2As_2O_3$$

(c) Ferrous oxide is oxidised to ferric oxide.

$$2\text{FeO} + \frac{1}{2}\text{O}_2 \longrightarrow \text{Fe}_2\text{O}_3$$

- (d) The entire mass becomes porous.
- (iii) Smelting: The calcined ore is mixed with limestone  $(CaCO_3)$  and coke in the ratio of 8:1:4 and introduced in a blast furnace for smelting.

#### Blast Furnace

Blast furnace is a chimney like tall steel structure lined with fire bricks, 25–60 metre high and 8–10 metre in diameter at its widest part (Fig. 14.2). The furnace has three main parts:

- (1) A double cup and cone arrangements: At the top, the furnace has a hopper which rests over a cup and cone arrangement. By this arrangement charge is introduced into the furnace and also the arrangement prevents the exit of gases during charging.
- (2) **Shaft:** It is formed by joining two cones, the upper one is called the body and the lower one is called bosh. At the upper part, there is a hole, through which the hot burnt mixture of waste gases escape. In the lower part, there are openings for the insertion of water cooled pipes called *tuyeres* through which a blast of hot air is sent upward in the furnace.
- (3) **Hearth:** This is the lowest part of the furnace and serves as a large crucible. It is provided with two holes one for the removal of slag and other for molten metal.

Theory of reduction of oxide ore of iron—see chapter 4.

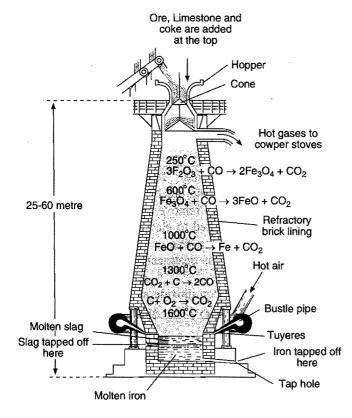

Fig. 14.2 Blast furnace for the manufacture of cast iron

The charge is introduced in the furnace by lowering the cup and cone arrangement and at the same time the furnace is lit and a blast of hot air is sent upwards through the *tuyeres*. The temperature varies from 1600°C to 250°C in the furnace from bottom to top. On the basis of variation in temperature, there are four zones where different chemical changes occur. The four zones are:

1. Combustion zone: This is the lowest part of the furnace above hearth where the temperature is about 1500°–1600°C. In this zone carbon burns in presence of hot air producing carbon dioxide and a lot of heat.

$$C + O_2 \longrightarrow CO_2 + 97.0$$
 kcals.

Carbon dioxide rises upwards and meets with red hot coke. It is reduced to carbon monoxide.

$$CO_2 + C \xrightarrow{1500^{\circ}C} 2CO$$

**2. Reduction zone:** This is the uppermost part of the furnace. The temperature varies from 250°C to 700°C. The oxide ore is reduced to iron in this zone. The reduction takes place through the following stages:

$$3Fe_2O_3 + CO \xrightarrow{300-400^{\circ}C} 2Fe_3O_4 + CO_2$$
 $Fe_3O_4 + CO \xrightarrow{500-600^{\circ}C} 3FeO + CO_2$ 
 $FeO + CO \xrightarrow{700^{\circ}C} Fe + CO_2$ 

However, the oxide ore which escapes reduction, gets completely reduced by carbon above 850°C.

Iron formed is called spongy iron. In the reduction reactions, heat is also evolved which decomposes part of carbon monoxide into carbon.

$$2CO \xrightarrow[iron]{Hot spongy} CO_2 + C$$

**3. Slag formation zone:** This is the central zone where the temperature varies from 800–1000°C. The limestone present in the charge decomposes into calcium oxide and carbon dioxide.

$$CaCO_3 \xrightarrow{1000^{\circ}C} CaO + CO_2$$

The calcium oxide acts as a flux as it combines with silica present as an impurity (gangue) to form a fusible slag of CaSiO<sub>3</sub>.

$$CaO + SiO_2 \longrightarrow CaSiO_3$$

Silicates, phosphates and manganates present as impurities in ore, are reduced to Si, P and Mn, respectively.

$$\begin{array}{c} P_4O_{10} + 10C \longrightarrow 4P + 10CO \\ SiO_2 + 2C \longrightarrow Si + 2CO \\ MnO_2 + 2C \longrightarrow Mn + 2CO \end{array}$$

These are partly absorbed by iron (spongy) and partly by slag.

$$2Ca_3(PO_3)_2 + 3SiO_2 + 10C \longrightarrow 3(2CaO \cdot SiO_2) + 4P + 10CO$$
  
 $3Fe + P \longrightarrow Fe_3P$ 

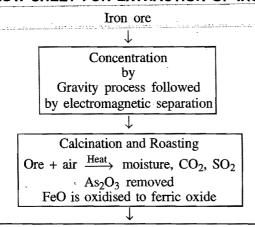

**4. Zone of fusion:** This is a zone just above the zone of combustion. The temperature ranges between 1200–1500°C. The spongy iron which has absorbed already C, Si, P, Mn, etc., melts at 1300°C and collects at the bottom of the hearth.

The slag which being lighter floats over the molten iron and prevents the oxidation of molten metal. The slag and molten metal are removed from their respective holes. The molten metal is run into moulds and is allowed to solidify.

Iron obtained from the blast furnace is called **pig iron.** It contains 93% iron, 5% carbon and rest silicon, manganese, phosphorus, etc., as impurities. The pig iron is remelted and cast or poured into moulds. This is known as cast iron. Hence, after remelting the pig iron becomes cast iron.

When the molten pig iron is cooled at once, the iron is called white cast iron, which contains carbon in the form of cementite, Fe<sub>3</sub>C and when the molten pig iron is cooled slowly and slowly, the iron is called as grey cast iron, which contains carbon in the form of graphite.

#### FLOW SHEET FOR EXTRACTION OF IRON

Smelting in a blast furnace (ore + coke + limestone). The following reactions occur.

Fe<sub>2</sub>O<sub>2</sub> +  $\frac{400 - 700^{\circ}\text{C}}{2}$  2Fe +  $\frac{3}{2}$ CO<sub>2</sub>

Fe<sub>2</sub>O<sub>3</sub> + 3CO 
$$\xrightarrow{400-700^{\circ}\text{C}}$$
 2Fe + 3CO<sub>2</sub> Spongy iron

CaCO<sub>3</sub>  $\xrightarrow{1000^{\circ}\text{C}}$  CaO + CO<sub>2</sub>
CaO + SiO<sub>2</sub>  $\longrightarrow$  CaSiO<sub>3</sub> (slag)

2CO  $\xrightarrow{\text{Hot iron}}$  CO<sub>2</sub> + C

SiO<sub>2</sub> + 2C  $\xrightarrow{1200^{\circ}\text{C}}$  Si + 2CO

MnO<sub>2</sub> + 2C  $\longrightarrow$  Mn + 2CO

P<sub>4</sub>O<sub>10</sub> + 10C  $\longrightarrow$  4P + 10CO

Spongy iron + C, Mn, Si, etc.  $\longrightarrow$  Impure iron

C·+ O<sub>2</sub>  $\xrightarrow{1600^{\circ}\text{C}}$  CO<sub>2</sub>

CO<sub>2</sub> + C  $\xrightarrow{1500^{\circ}\text{C}}$  2CO

(Fe = 93%; C = 5% and impurities of Mn, P, Si, etc. = 2%)

Cast iron

Pig iron

Remelted

and cooled

# 14.10 TYPES OF IRON

There are three commercial varieties of iron depending on their carbon content.

## (i) Cast Iron

It is the most impure form of iron and contains the highest percentage of carbon from 2.5 to 5 per cent and about 2 per cent of other impurities like Si, P, Mn and S. Cast iron is of two types:

- (a) White cast iron: Carbon is present in the form of cementite, Fe<sub>3</sub>C.
- (b) Grey cast iron: Carbon is present in the form of graphite. Cast iron melts at about 1250°C (due to presence of impurities) whereas pure iron melts at 1530°C. The molten cast iron expands on solidification and hence it produces good castings. Various articles such as stoves, pipes, radiators, railway sleepers, gutter pipes, toys, etc., are prepared from cast iron. Cast iron does not rust easily and neither be tempered. Due to high carbon content, it is hard and brittle and cannot be welded. It has very little ductility and thus cast iron is not suitable for forging.

## **(ii) Wrought Iron**

It is the purest form of iron. It contains the lowest percentage of carbon from 0.1 to 0.25 per cent and 0.3 per cent other impurities. It is manufactured from cast iron by **puddling process.** 

Wrought iron is manufactured in a special type of reverberatory furnace called puddling furnace, the hearth of which is lined with haematite, Fe<sub>2</sub>O<sub>3</sub>. The cast iron is melted on the hearth of the furnace by the hot gases and stirred with long iron rods. The impurities of cast iron are rapidly oxidised by oxygen of haematite (lining). Oxides of carbon and sulphur being volatile escape while those of Mn, P and Si form slag.

$$3C + Fe_2O_3 \longrightarrow 2Fe + 3CO$$

$$3Si + 2Fe_2O_3 \longrightarrow 3SiO_2 + 4Fe$$

$$3Mn + Fe_2O_3 \longrightarrow 3MnO + 2Fe$$

$$MnO + SiO_2 \longrightarrow MnSiO_3 \text{ (Slag)}$$

$$6P + 5Fe_2O_3 \longrightarrow 3P_2O_5 + 10Fe$$

$$P_2O_5 + Fe_2O_3 \longrightarrow 2FePO_4 \text{ (Slag)}$$

With the removal of impurities, the melting point of the metal rises and it becomes a semi-solid mass. The semi-solid mass is taken out in the form of balls and is beaten under steam hammers to squeeze out as much of slag as possible. This produces almost pure iron known as wrought iron.

# ■ Properties

(i) Wrought iron is extremely tough, highly malleable and ductile. (ii) It softens at about 1000°C and then it can be forged and welded. (iii) On account of the presence of very small percentage of slag, it has fibrous structure and thus, can withstand high stresses. (iv) Wrought iron is resistant towards rusting and corrosion.

#### **■** Uses

It is used to make chains, nails, hooks, bolts, agricultural implements, electromagnets, bars, wires, etc.

## (iii) Steel

This is the most important commercial variety of iron. The percentage of carbon in this form of iron is midway between that of cast iron and wrought iron, *i.e.*, 0.25 to 2 per cent. There are many varieties of steel depending on the amount of carbon present in it.

- (a) Mild steels: These contain low percentage of carbon. Such steels show the properties of wrought iron along with elasticity and hardness.
- **(b) Hard steels:** These contain high percentage of carbon. They are hard and brittle.
- (c) Special steels or alloy steels: Steel mixed with small amount of nickel, cobalt, chromium, tungsten, molybdenum, manganese, etc., acquires special properties. Such products are called special steels or alloy steels. Some important alloy steels are listed below:

Name of the alloy steel	Metal added	Properties	Uses
1. Invar	36% Ni	Coefficient of expansion is very small	Measuring tapes, pendulums
2. Chromevan- adium steel	1% Cr; 0.15%V	High tensile strength	Springs, shafts, axles
3. Manganese steel	12-15% Mn	Hard and tough	Rock crushing machinery, almirah, helmets
4. Stainless steel	11.5% Cr; 2% Ni	Resists corrosion	Common articles
5. Tungsten steel	14–20% W; 3–8% Cr	Very hard	High speed tools
6. Alnico	60% Fe, 12% Al, 20% Ni, 8% Co	Highly magnetic	For making perma- nent magnets
7. Permalloy	21% Fe, 78% Ni and carbon	Strongly magne- tised by electric current, loses magnetism when current is cut off.	For making electromagnets, ocean cables, etc.

#### Manufacture of Steel

Many methods are used for the manufacture of steel. Some are described below:

(i) The Bessemer's process: The process is based on the fact that impurities of pig iron are completely oxidised in presence of hot air blast, *i.e.*, virtually wrought iron is obtained. This is then mixed with a known amount of *spiegeleisen*, an alloy of iron, manganese and carbon to obtain steel.

The process is carried out in Bessemer converter lined with silica bricks. The molten pig iron is introduced in the converter

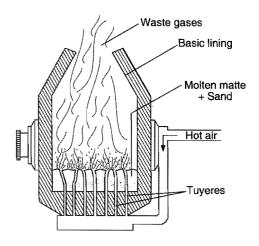

Fig. 14.3

and a blast of hot air is blown through it from the bottom and keeping the mouth of the converter vertically upwards. Silica and manganese present in pig iron are first oxidised and then combine to form slag.

$$Si + O_2 \longrightarrow SiO_2$$
  
 $2Mn + O_2 \longrightarrow 2MnO$   
 $MnO + SiO_2 \longrightarrow MnSiO_3$ 

In the end, carbon is oxidised to carbon monoxide which burns with blue flame at the mouth of the converter. Some iron is also oxidised which converts the carbon into carbon monoxide.

$$4\text{Fe} + 3\text{O}_2 \longrightarrow 2\text{Fe}_2\text{O}_3$$
  
 $\text{Fe}_2\text{O}_3 + 3\text{C} \longrightarrow 2\text{Fe} + 3\text{CO}$ 

When whole of the carbon is oxidised, the blue flame suddenly dies out. The air supply is stopped for a while and the requisite amount of *spiegeleisen* is added. The blast is continued just for a moment to ensure complete mixing. The resulting product is the manganese steel.

When cast iron or pig iron contains phosphorus as an impurity, a basic lining of CaO or MgO is used in the Bessemer converter. Phosphorus is oxidised to  $P_4O_{10}$  which combines with CaO to form calcium phosphate as slag.

$$\begin{array}{c} \text{4P} + 5\text{O}_2 \longrightarrow \text{P}_4\text{O}_{10} \\ \text{6CaO} + \text{P}_4\text{O}_{10} \longrightarrow 2\text{Ca}_3(\text{PO}_4)_2 \end{array}$$

This slag is used as a fertilizer and known as Thomas slag.

(ii) Open hearth process or Siemens-Martin process: This is the modern process and the furnace used consists of an open hearth. The hearth is lined with silica or calcined dolomite (CaO·MgO) depending upon the nature of impurities present in pig or cast iron. Silica lining is used if the impurities are manganese, silicon, etc., and calcined dolomite lining is used if much of phosphorus is present. A high temperature of about 1500°C is generated by burning producer gas which works on regenerative system of heat economy (Fig. 14.4).

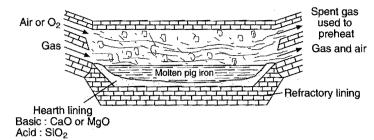

Fig. 14.4

The charge consists of pig or cast iron, iron scrap, iron ore (haematite) and lime. The charge is heated on the hearth of the furnace. The impurities are oxidised by iron ore.

$$3Si + 2Fe_2O_3 \longrightarrow 4Fe + 3SiO_2$$

$$3Mn + Fe_2O_3 \longrightarrow 2Fe + 3MnO$$

$$MnO + SiO_2 \longrightarrow MnSiO_3 \text{ (Slag)}$$

$$3C + Fe_2O_3 \longrightarrow 2Fe + 3CO$$

$$12P + 10Fe_2O_3 \longrightarrow 3P_4O_{10} + 20Fe$$

$$6CaO + P_4O_{10} \longrightarrow 2Ca_3(PO_4)_2 \text{ (Slag)}$$

$$CaO + SiO_2 \longrightarrow CaSiO_3 \text{ (Slag)}$$

$$2Fe_2O_3 + 3S \longrightarrow 3SO_2 + 4Fe$$

Samples of steel are drawn from time to time and tested for carbon content. Finally *spiegeleisen* (an alloy of iron, manganese and carbon) is added to the molten mass to obtain desired steel. The process takes about 8 to 10 hours for completion. The process takes longer time than Bessemer's process but it has following advantage over the Bessemer's process.

- (a) The temperature can be controlled as the heating is done externally.
- (b) As it is a slower process, it can be controlled in better way. The composition and quality can be well controlled.
- (c) The loss of iron in this process is only 4% while the loss is about 15% in Bessemer's process.
  - (d) In this process scrap iron is reused.
  - (e) This yields better quality of steel.
- (f) A considerable economy of the fuel is achieved by using the regenerative system.

(iii) The electric process: This process is similar to open hearth process with a difference that heating is done electrically. The steel of much better quality can be obtained but the process is rather costly.

The process consists in heating of the charge having pig or cast iron, scrap iron, iron ore (haematite) and lime in an electric furnace using vertical carbon electrodes. When the arc is struck between the electrodes, the high temperature of about 2000°C generated melts the charge and chemical reactions start instantaneously. The impurities are oxidised by iron ore in the same fashion as in the open hearth process.

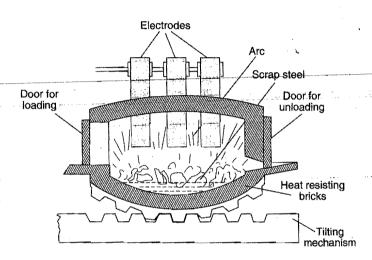

Fig. 14.5

This method is especially useful for the production of the alloy steels.

#### Heat Treatment of Steels

The properties of steel depend on three factors:

(i) Carbon content: With the increase of carbon content the hardness and tensile strength of the steel increases while ductility decreases.

#### COMPARISON OF CAST IRON, WROUGHT IRON AND STEEL

	Property	Cast iron	Wrought iron	Steel
1.	Chemical composition	Iron 93–95%	Iron 99.5-99.8%	Iron 98–99.5%
		Carbon 2.5-5%	Carbon 0.1-0.21%	Carbon 0.25 to 2.0%
	·	Impurities about 2%	Impurities about 0.3%	
2.	Melting point	Lowest about 1200°C	Highest about 1500°C	Between 1300-1400°C
3.	Hardness	Very hard	Soft	Medium hardness
4.	Malleability	Brittle	Malleable	Malleable and brittle
5.	Welding	Cannot be welded	Can be welded easily	Can be welded with difficulty
6.	Tempering	Cannot be tempered	Cannot be tempered	Can be tempered
7.	Magnetisation	Cannot be permanently magnetised	Magnetisation is not permanent but easy	Can be permanently magnetised
8.	Structure	Crystalline	Fibrous	Granular

- (ii) Presence of other metals: The presence of Si gives steel a fibrous structure. Presence of Mn produces elasticity and increases tensile strength. Cr imparts resistance to chemical action.
- (iii) Heat treatment: The hardness and elasticity of the steel can be changed by heating the steel at different temperatures and then allowing to cool it in different ways. The following heat treatments are given to steel:
- (a) Annealing: It is a process of heating steel to bright redness and then cooling it very slowly. This treatment makes the steel soft and ductile. This type of steel is used in fabrication process.
- (b) Quenching: It is a process of heating steel to bright redness and then cooling it suddenly by plunging it in water or oil. Such a steel is extremely hard and brittle. It has very low elasticity.
- (c) **Tempering:** It is a process of heating the quenched steel to a temperature much below redness and then cooling it slowly. Such steel is neither so hard nor so brittle. In the process of tempering, a thin film of the oxide is formed on the surface of steel. The colour of the oxide film depends on the temperature at which the quenched steel is heated.

Temperature range	Colour of the oxide film
200-230°C	Yellow
225–270°C	Brown
300℃	Blue

The surface treatment of the steel is done by the following two processes:

- (a) Case hardening: The process of producing a thin coating of hardened steel on the surface of the mild steel is called case hardening. This is done by heating the mild steel with charcoal and then plunging into oil. This produces a thin coating of hardened steel on the surface. Such a steel becomes resistant to wear and tear.
- **(b) Nitriding:** The process of producing a hard coating of iron nitride on the surface of steel is called nitriding. Steel is heated in the atmosphere of dry ammonia at 500–600°C for about 3 to 4 days when a hard coating of iron nitride is produced on the surface.

# 14.11 PASSIVITY OF IRON

The following are the common properties of iron.

- (a) It evolves hydrogen gas, when made to react with dilute HCl or dilute  $H_2SO_4$ .
- (b) It precipitates silver from silver nitrate solution and copper from copper sulphate solution.

But if a piece of iron is first dipped in concentrated nitric acid for sometime and then made to react with the above reagents, neither hydrogen is evolved nor silver or copper are precipitated. Thus, iron by treatment with concentrated nitric acid has lost its usual properties or it has been rendered inert or passive. Such behaviour is not only shown by iron but also by many other metals like Cr, Co, Ni, Al, etc. This phenomenon is known as passivity and the chemical substances which bring passivity are called passivators.

"The inertness exhibited by metals under conditions when chemical activity is to be expected is called chemical passivity." Iron can be rendered passive by other oxidising agents like chromic acid, KMnO<sub>4</sub>, conc. H<sub>2</sub>SO<sub>4</sub>, etc. The passivity of the iron is believed to be due to formation of an extremely thin film (invisible) of oxide on the surface of iron. Passive iron can be made active by scratching or heating in a reducing atmosphere of H<sub>2</sub> or CO, or heating in HNO<sub>3</sub> upto 75°C.

# 14.12 COMPOUNDS OF IRON

## Ferrous Sulphate (Green vitriol), FeSO<sub>4</sub>·7H<sub>2</sub>O

This is the best known ferrous salt. It occurs in nature as *copperas* and is formed by the oxidation of pyrites under the action of water and atmospheric air.

$$2FeS_2 + 7O_2 + 2H_2O \longrightarrow 2FeSO_4 + 2H_2SO_4$$

It is commonly known as harakasis.

**Preparation.** (i) It is obtained by dissolving scrap iron in dilute sulphuric acid.

$$Fe + H_2SO_4 \longrightarrow FeSO_4 + H_2$$

The solution is crystallised by the addition of alcohol as ferrous sulphate is sparingly soluble in it.

(ii) It can also be prepared in the laboratory from the Kipp's waste. The excess of sulphuric acid is neutralised by heating with a small quantity of iron fillings. The solution is then crystallised.

Manufacture: Commercially, ferrous sulphate is obtained by the slow oxidation of iron pyrites in the presence of air and moisture. The pyrites are exposed to air in big heaps.

$$2FeS_2 + 2H_2O + 7O_2 \longrightarrow 2FeSO_4 + 2H_2SO_4$$

The free sulphuric acid is removed by the addition of scrap iron. On crystallisation green crystals are obtained.

## **■** Properties

(i) Hydrated ferrous sulphate (FeSO<sub>4</sub>·7H<sub>2</sub>O) is a green crystalline compound. Due to atmospheric oxidation, the crystals acquire brownish-yellow colour due to formation of basic ferric sulphate.

$$4\text{FeSO}_4 + 2\text{H}_2\text{O} + \text{O}_2 \longrightarrow 4\text{Fe(OH)} \cdot \text{SO}_4$$
Basic ferric sulphate

(ii) Action of heat: At 300°C, it becomes anhydrous. The anhydrous ferrous sulphate is colourless. The anhydrous salt when strongly heated, breaks up to form ferric oxide with the evolution of SO<sub>2</sub> and SO<sub>3</sub>.

$$FeSO_{4} \cdot 7H_{2}O \xrightarrow[-7H_{2}O]{300^{\circ}C} 2FeSO_{4} \xrightarrow[\text{White}]{High} Fe_{2}O_{3} + SO_{2} + SO_{3}$$

(iii) The aqueous solution of ferrous sulphate is slightly acidic due to its hydrolysis.

$$FeSO_4 + 2H_2O \rightleftharpoons Fe(OH)_2 + H_2SO_4$$
  
Weak base Strong acid

- (iv) Ferrous sulphate is a strong reducing agent.
- (a) It decolourises acidified potassium permanganate.  $2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$  $[2FeSO_4 + H_2SO_4 + O \longrightarrow Fe_2(SO_4)_3 + H_2O] \times 5$

$$10\text{FeSO}_4 + 2\text{KMnO}_4 + 8\text{H}_2\text{SO}_4 \longrightarrow 5\text{Fe}_2(\text{SO}_4)_3 + \text{K}_2\text{SO}_4 + 2\text{MnSO}_4 + 8\text{H}_2\text{O}_4$$

(b) It turns potassium dichromate (acidified) green as dichromate is reduced to chromic salt (green).

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$

$$= \underbrace{[2FeSO_4 + H_2SO_4 + O \longrightarrow Fe_2(SO_4)_3 + H_2O] \times 3}_{CF_2O_2 \longrightarrow Fe_2$$

$$6FeSO_4 + K_2Cr_2O_7 + 7H_2SO_4 \longrightarrow 3Fe_2(SO_4)_3 + K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O_4$$

(c) It reduces gold chloride to gold.

$$AuCl_3 + 3FeSO_4 \longrightarrow Au + Fe_2(SO_4)_3 + FeCl_3$$

(d) It reduces mercuric chloride to mercurous chloride.

$$[2HgCl2 \longrightarrow Hg2Cl2 + 2Cl] \times 3$$

$$[3FeSO4 + 3Cl \longrightarrow Fe2(SO4)3 + FeCl3] \times 2$$

$$6HgCl_2 + 6FeSO_4 \longrightarrow 3Hg_2Cl_2 + 2Fe_2(SO_4)_3 + 2FeCl_3$$

(v) A cold solution of ferrous sulphate absorbs nitric oxide forming dark brown addition compound, nitroso ferrous sulphate.

The NO gas is evolved when the solution is heated.

- (vi) It forms double sulphates of the composition  $R_2SO_4$ ·FeSO<sub>4</sub>·6H<sub>2</sub>O where R = an alkali metal or NH<sub>4</sub><sup>+</sup> radical. (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>·FeSO<sub>4</sub>·6H<sub>2</sub>O (ferrous ammonium sulphate) is known as Mohr's salt.
- (vii) It combines with potassium cyanide (excess) forming potassium ferrocyanide, K<sub>4</sub>Fe(CN)<sub>6</sub>.

$$FeSO_4 + 2KCN \longrightarrow Fe(CN)_2 + K_2SO_4$$

$$Fe(CN)_2 + 4KCN \longrightarrow K_4Fe(CN)_6$$

$$FeSO_4 + 6KCN \longrightarrow K_4Fe(CN)_6 + K_2SO_4$$

#### Uses

(i) Ferrous sulphate is used for making blue black ink. The ink is prepared by mixing a solution of tannin and ferrous sulphate. A colourless iron salt of tannic acid is formed. A blue dye (usually indigo) is added. The writing with this ink is blue but soon on exposure to air, it becomes black on account of oxidation of colourless ferrous salt into black ferric salt.

- (ii) It is used as a mordant in dyeing.
- (iii) It is also used as an insecticide in agriculture.
- (iv) It is employed as a laboratory reagent and in the preparation of Mohr's salt.

## Ferrous Ammonium Sulphate (Mohr's salt) (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>·FeSO<sub>4</sub>·6H<sub>2</sub>O

**Preparation:** The double salt is best prepared by making saturated solutions of pure ferrous sulphate and pure ammonium sulphate in air free distilled water at 40°C. Both the solutions are mixed and allowed to cool. Generally, few drops of sulphuric acid and a little iron wire are added before crystallisation as to prevent oxidation of ferrous sulphate into ferric sulphate. The salt is obtained as pale green crystals.

### Properties

It is pale green crystalline compound which does noteffloresce like ferrous sulphate. It is less readily oxidised in the solid state. It is, therefore, a better volumetric reagent in preference to ferrous sulphate. Chemically, it is similar to ferrous sulphate. All the chemical reactions observed in the case of ferrous sulphate are given by ferrous ammonium sulphate.

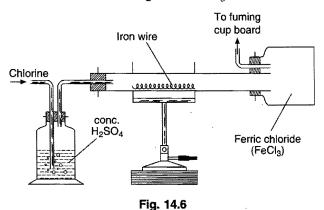

## Ferric Chloride, FeCl<sub>3</sub>

This is the most important ferric salt. It is known in anhydrous and hydrated forms. The hydrated form consists of six water molecules, FeCl<sub>3</sub>·6H<sub>2</sub>O.

**Preparation:** (i) Anhydrous ferric chloride is obtained by passing dry chlorine gas over heated iron fillings (Fig. 14.6).

The vapours are condensed in a bottle attached to the outlet of the tube.

$$2\text{Fe} + 3\text{Cl}_2 \longrightarrow 2\text{FeCl}_3$$

(ii) Hydrated ferric chloride is obtained by the action of hydrochloric acid on ferric carbonate, ferric hydroxide or ferric oxide.

$$Fe_{2}(CO_{3})_{3} + 6HCl \longrightarrow 2FeCl_{3} + 3H_{2}O + 3CO_{2}$$

$$Fe(OH)_{3} + 3HCl \longrightarrow FeCl_{3} + 3H_{2}O$$

$$Fe_{2}O_{3} + 6HCl \longrightarrow 2FeCl_{3} + 3H_{2}O$$

The solution on evaporation and cooling deposits yellow crystals of hydrated ferric chloride, FeCl<sub>3</sub>·6H<sub>2</sub>O.

## ■ Properties

(i) Anhydrous ferric chloride is a dark red deliquescent solid. It is sublimed at about 300°C and its vapour density corresponds to dimeric formula, Fe<sub>2</sub>Cl<sub>6</sub>. The dimer dissociates at high temperatures to FeCl<sub>3</sub>. The dissociation into FeCl<sub>3</sub> is complete at 750°C. Above this temperature it breaks into ferrous chloride and chlorine.

Fe<sub>2</sub>Cl<sub>6</sub> 
$$\stackrel{750^{\circ}\text{C}}{\rightleftharpoons}$$
 2FeCl<sub>3</sub>  $\stackrel{\text{Above 750^{\circ}\text{C}}}{\rightleftharpoons}$  2FeCl<sub>2</sub> + Cl<sub>2</sub>

(ii) Anhydrous ferric chloride behaves as a covalent compound as it is soluble in non-polar solvents like ether, alcohol, etc. It is represented by chlorine bridge structure.

(iii) It dissolves in water. The solution is acidic in nature due to its hydrolysis as shown below:

$$FeCl_3 + 3HOH \Longrightarrow Fe(OH)_3 + 3HCl$$

The solution is stabilised by the addition of hydrochloric acid to prevent hydrolysis.

(iv) Anhydrous ferric chloride absorbs ammonia.

$$FeCl_3 + 6NH_3 \longrightarrow FeCl_3 \cdot 6NH_3$$

- (v) Ferric chloride acts as an oxidising agent.
- (a) It oxidises stannous chloride to stannic chloride.

$$2FeCl_3 + SnCl_2 \longrightarrow 2FeCl_2 + SnCl_4$$

(b) It oxidises SO<sub>2</sub> to H<sub>2</sub>SO<sub>4</sub>.

$$2\text{FeCl}_3 + \text{SO}_2 + 2\text{H}_2\text{O} \longrightarrow 2\text{FeCl}_2 + \text{H}_2\text{SO}_4 + 2\text{HCl}$$

(c) It oxidises H<sub>2</sub>S to S.

or

$$2FeCl_3 + H_2S \longrightarrow 2FeCl_2 + 2HCl + S$$

(d) It liberates iodine from KI.

$$2FeCl_3 + 2KI \longrightarrow 2FeCl_2 + 2KCl + I_2$$

(e) Nascent hydrogen reduces FeCl<sub>3</sub> into FeCl<sub>2</sub>.

$$FeCl_3 + H \longrightarrow FeCl_2 + HCl$$

(vi) When ammonium hydroxide is added to the solution of ferric chloride, a reddish-brown precipitate of ferric hydroxide is formed.

$$FeCl_3 + 3NH_4OH \longrightarrow Fe(OH)_3 + 3NH_4Cl$$

(vii) When a solution of thiocyanate ions is added to ferric chloride solution, a deep red colouration is produced due to formation of a complex salt.

FeCl<sub>3</sub> + NH<sub>4</sub>CNS 
$$\longrightarrow$$
 Fe(SCN)Cl<sub>2</sub> + NH<sub>4</sub>Cl  
FeCl<sub>3</sub> + 3NH<sub>4</sub>CNS  $\longrightarrow$  Fe(SCN)<sub>3</sub> + 3NH<sub>4</sub>Cl

(viii) Ferric chloride forms a complex, prussian blue with potassium ferrocyanide.

$$4\text{FeCl}_3 + 3\text{K}_4\text{Fe}(\text{CN})_6 \longrightarrow \text{Fe}_4[\text{Fe}(\text{CN})_6]_3 + 12\text{KCl}$$
Prussian blue
(Ferri ferrocyanide)

(ix) On heating hydrated ferric chloride FeCl<sub>3</sub>·6H<sub>2</sub>O, anhydrous ferric chloride is not obtained. It is changed to Fe<sub>2</sub>O<sub>3</sub> with evolution of H<sub>2</sub>O and HCl.

$$2[FeCl_3 \cdot 6H_2O] \xrightarrow{Heat} Fe_2O_3 + 6HCl + 9H_2O$$

Hydrated ferric chloride may be dehydrated by heating with thionyl chloride.

$$FeCl_3 \cdot 6H_2O + 6SOCl_2 \longrightarrow FeCl_3 + 12HCl + 6SO_2$$

#### **■** Uses

(i) The alcoholic solution is used in medicine under the name tincture ferri perchloride. (ii) It is used as a laboratory reagent in the detection of acetates and phenols and also as an oxidising agent. (iii) It is used for making prussian blue.

# 14.12 CORROSION OF IRON

Corrosion is defined as the gradual transformation of a metal into its combined state because of the reaction with the environment. Metals are usually extracted from their ores. Nature tries to convert them again into the ore form. The process by which the metals have the tendency to go back to their combined state, is termed corrosion.

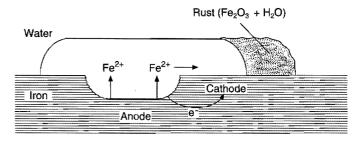

Fig. 14.7

When iron is exposed to moist air, it is found covered with a reddish-brown coating which can easily be detached. The reddish-brown coating is called 'rust'. Thus, the corrosion of iron or formation of the rust is called **rusting.** The composition of the rust is not certain but it mainly contains hydrated ferric oxide,  $2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$ , together with a small quantity of ferrous carbonate. The rust is formed by the action of water on iron in presence of dissolved oxygen and carbon dioxide. It has been observed that impure iron is more prone to rusting.

The following are the favourable conditions for the rusting of iron:

- (i) Presence of moisture
- (ii) Presence of a weakly acidic atmosphere
- (iii) Presence of impurity in the iron.

Various theories have been proposed to explain the phenomenon of rusting of iron but the accepted theory is the

modern electrochemical theory. When impure iron comes in contact with water containing dissolved carbon dioxide, a voltaic cell is set up. The iron and other impurities act as electrodes while water having dissolved oxygen and carbon dioxide acts as an electrolyte. Iron atoms pass into solution as ferrous ions.

$$Fe \longrightarrow Fe^{2+} + 2e$$

Iron, thus, acts as anode.

The impurities act as cathode. At the cathode, the electrons are used in forming hydroxyl ions.

$$H_2O + O + 2e \longrightarrow 2OH^-$$

In presence of dissolved oxygen, ferrous ions are oxidised to ferric ions which combine with hydroxyl ions to form ferric hydroxide.

$$Fe^{3+} + 3OH^{-} \longrightarrow Fe(OH)_{3}$$
Rust

$$[2Fe^{2+} + H_2O + O \longrightarrow 2Fe^{3+} + 2OH^-]$$

Corrosion or rusting is a surface phenomenon and thus, the protection of the surface prevents the corrosion. Iron can be protected from the rusting by use of following methods:

- (i) Applying paints, lacquers and enamels on the surface of iron.
- (ii) By forming a firm and coherent protective coating of ferrosoferric oxide. This is done by passing steam over hot iron.
- (iii) By coating a thin film of zinc, tin, nickel, chromium, aluminium, etc.

# 14.14 POSITION OF COINAGE METALS IN PERIODIC TABLE

Group		vin		1B	mB
Period	(8)	(9)	(10)	(11)	(12)
4	Fe 26	Co 27	Ni 28	Cu 29	Zn 30
5	Ru 44	Rh 45	Pd 46	Ag 47	Cd 48
6	Os 76	Ir 77	Pt 78	Au 79	Hg 80

IB subgroup (group 11) of the periodic table consists of four metals—copper (Cu), silver (Ag), gold (Au) and unununium (Uuu)\*. These are collectively called as copper metals (copper being the predominant member) or coinage metals or currency metals because these (Cu, Ag and Au) have been used in the past in making coins for currency. These are d-block elements as the differentiating electron is accommodated on (n-1)d energy shell. Copper is a member of 3d series, silver is a member of 4d series, Au is a member of 5d series and Uuu is a member of 6d series. They show relationship with Ni, Pd and Pt (group VIII) which are their left hand neighbours and also with Zn, Cd and Hg (group IIB) which are their right hand neighbours in the periodic table. Thus, these occupy position

between VIII and IIB groups of the periodic table. Their inclusion in the same subgroup is justified on the basis of:

- (a) same electronic configuration and
- (b) similar characteristics or gradation in the properties.
- 1. Electronic configuration: They have similar electronic configuration. The distribution of the electrons in various energy shells of these atoms is shown below:

Cu 29 2, 8, 18, 1 
$$1s^2, 2s^22p^6, 3s^23p^63d^{10}, 4s^1$$
  
Ag 47 2, 8, 18, 18, 1  $1s^2, 2s^22p^6, 3s^23p^63d^{10}, 4s^24p^64d^{10}, 5s^1$   
Au 79 2, 8, 18, 32, 18, 1  $1s^2, 2s^22p^6, 3s^23p^63d^{10}, 4s^24p^64d^{10}4f^{14}, 5s^25p^65d^{10}, 6s^1$   
Uuu 111 2, 8, 18, 32, 32, 18, 1  $1s^2, 2s^22p^6, 3s^23p^63d^{10}, 4s^24p^64d^{10}4f^{14}, 5s^25p^65d^{10}5f^{14}, 6s^26p^66d^{10}, 7s^1$ 

The electronic configuration shows that the outermost shell of these elements has one electron  $(ns^1)$  while the penultimate shell contains 18 electrons  $[(n-1)s^2p^6d^{10}]$ , i.e., general configuration  $(n-1)s^2(n-1)p^6(n-1)d^{10}ns^1$ . However, (n-1)d shell has not attained stability and one or more electrons sometimes jump to the outermost shell thereby increasing the valency electrons. As a result, the atoms or ions take up the new configuration.

It is for this reason that these elements are considered as the end members of transition series. In higher valency states these elements, therefore, show properties similar to those of the corresponding transition elements of VIII group.

**2. Valency:** Being transition elements, these show variable valency. Copper forms both cuprous (Cu<sup>+</sup>) and cupric (Cu<sup>2+</sup>) ions. The cuprous ions, however, have a tendency to change into cupric and thus, soluble cuprous salts are not stable.

$$2Cu^{+} \longrightarrow Cu^{2+} + Cu$$

The insoluble cuprous salts as  $Cu_2Cl_2$ ,  $Cu_2I_2$ ,  $Cu_2(CN)_2$ ,  $Cu_2(CNS)_2$  are stable.

Silver shows mainly monovalency. The compounds of divalent silver are rare.

Gold like copper also forms two series of salts showing monovalency (aurous salts, Au<sup>+</sup>) and trivalency (auric salts, Au<sup>3+</sup>). The aurous salts are not stable and change into auric salts.

$$3Au^+ \longrightarrow Au^{3+} + 2Au$$
encies are: Copper: Divalence

Thus, stable valencies are: Copper; Divalency

Silver; Monovalency Gold; Trivalency

<sup>\*</sup>Uuu is a synthetic and radioactive element. It is unstable and not much is known about its properties.

**3. Physical Properties:** (a) These are tough, ductile and highly malleable metals. Silver and gold are more ductile and malleable than copper. (b) They are good conductors of heat and electricity. Silver is the best conductor. (c) They have high melting and boiling points. The availability of inner d electrons enhances the bonding between atoms in the metal crystal and results in the greater hardness and higher melting points of these elements like other transition elements.

Metal	Cu	Ag	Au
M.Pt. (°C)	1083	961	1063
B.Pt. (°C)	2595	2180	2700

(d) Atomic size: The atomic size are relatively small. Gold and silver have nearly the same atomic size. (This is due to lanthanide contraction associated with the filling of the 4f shell). The atomic volumes are also small and both silver and gold have the same values.

Metal	Cu	Ag	Au
Atomic radii Å	1.17	1.34	1.34
Atomic volume	7.1	10.3	10.2

**(e) Density:** These are heavy metals. Density increases gradually as the atomic number increases.

Metal	Cu	Ag	Au
Density	8.96	10.5	19.3

**(f) Ionisation Energy:** Because of the smaller atomic size and increased nuclear charge, their ionisation energies are high. The ionisation energies do not show the expected trend with increasing atomic number; the values decrease from copper to silver but increase in going to gold.

Metal	Cu	Ag	Au
I.E. (eV)	7.72	7.57	9.2

The unexpected behaviour from Ag to Au is due to the fact that the atomic size of Ag and Au are the same while atomic charge increases from 47 to 79.

**(g) Oxidation potentials:** The standard oxidation potentials of coinage metals are negative.

$$Cu \longrightarrow Cu^{2+} + 2e \qquad E_{ox}^{\circ} = -0.34 \text{ volt}$$

$$Ag \longrightarrow Ag^{+} + e \qquad E_{ox}^{\circ} = -0.80 \text{ volt}$$

$$Au \longrightarrow Au^{3+} + 3e \qquad E_{ox}^{\circ} = -1.42 \text{ volt}$$

$$Cu \longrightarrow Cu^{+} + e \qquad E_{ox}^{\circ} = -0.52 \text{ volt}$$

$$Au \longrightarrow Au^{+} + e \qquad E_{ox}^{\circ} = -1.70 \text{ volt}$$

The values suggest that the atoms of coinage metals have little tendency to lose electron or electrons. Thus, these elements are feebly electropositive. The nobility increases in the order  $Cu \longrightarrow Ag \longrightarrow Au$ . Because of nobility, they are frequently found in their native state (silver and gold almost exclusively).

(h) Colour of the salts: The monovalents salts are colourless as they have  $(n-1)d^{10}$  configuration.

Cu<sup>+</sup> 2, 8, 18 (3
$$d^{10}$$
)  
Ag<sup>+</sup> 2, 8, 18, 18 (4 $d^{10}$ )  
Au<sup>+</sup> 2, 8, 18, 32, 18 (5 $d^{10}$ )

The salts in higher oxidation states are coloured as unpaired orbital or orbitals are present in (n-1)d energy shell.

$$Cu^{2+}$$
 2, 8, 17 (one 3*d* orbital singly occupied)  
 $Ag^{2+}$  2, 8, 18, 17 (one 4*d* orbital singly occupied)  
 $Au^{3+}$  2, 8, 18, 32, 16 (two 5*d* orbitals singly occupied)

Cu (II) salts are generally bluish or green, and Au (III) salts are yellow.

- (i) Magnetic nature: Cu (I), Ag (I) and Au (I) ions are diamagnetic as all the orbitals are fully paired while Cu (II), Ag (II) and Au (III) ions are paramagnetic as one or two orbitals are singly occupied.
- **4. Chemical Properties:** The chemical activity of a metal depends on the three hypothetical stages, each one involving an energy change.

$$\begin{array}{c} \text{Metal} \xrightarrow{\text{(Sublimation energy)}} & \text{Gaseous atoms} \xrightarrow{\text{(Ionisation potential)}} & \text{Ions} \\ & \xrightarrow{\text{(Hydration energy)}} & \text{Hydrated ions} \end{array}$$

A high heat of sublimation and high ionisation potential will reduce the tendency of the metal to react. In the case of coinage metals both sublimation energy and ionisation potential have very high values and thus, coinage metals are less reactive. The chemical activity decreases from Cu to Au.

- (a) Action of air: Gold and silver are not affected by air but copper on long exposure becomes converted with a greyish green film of basic carbonate, CuCO<sub>3</sub>Cu(OH)<sub>2</sub>.
- **(b) Affinity for oxygen:** Their affinity for oxygen decreases from copper to gold. Only copper combines with oxygen on heating. Copper oxide when strongly heated is reduced to cuprous oxide, silver oxide breaks up into silver and oxygen at about 300°C whereas gold oxide breaks up at 250°C. Cu<sub>2</sub>O difficult to break.

$$2Ag_2O \xrightarrow{300^{\circ}C} 4Ag + O_2$$

$$2Au_2O \xrightarrow{250^{\circ}C} 4Au + O_2$$

(c) Action of water: The coinage metals are not affected by water or steam. However, copper is attacked by steam at red hot state.

Cu (red hot) + 
$$H_2O \longrightarrow CuO + H_2$$

- (d) Action of sulphur: Both copper and silver combine directly with sulphur. Both copper and silver are found in the nature in the form of sulphides.
- (e) Action of halogens: Coinage metals react much more readily with the free halogens than with any other element. Copper combines with halogens at ordinary temperatures.

$$Cu + X_2 \longrightarrow CuX_2$$

Silver reacts slowly while, gold reacts with dry halogens on heating.

$$2Au + 3X_2 \longrightarrow 2AuX_3$$

(f) Action of acids: Copper, silver and gold do not liberate hydrogen from dilute acids as they are present below hydrogen in the electrochemical series. Copper dissolves in het dilute acids HCl or H<sub>2</sub>SO<sub>4</sub> only in presence of air or oxygen.

$$Cu + 2HCl + \frac{1}{2}O_2 \longrightarrow CuCl_2 + H_2O$$

$$Cu + H_2SO_4 + \frac{1}{2}O_2 \longrightarrow CuSO_4 + H_2O$$
(dil.)

Copper and silver dissolve readily in acids which act as oxidising agents, e.g., dil. and conc. HNO<sub>3</sub>, conc. H<sub>2</sub>SO<sub>4</sub>.

$$\begin{array}{c} H_2SO_4(\text{conc.}) \longrightarrow H_2O + SO_2 + O \\ \hline Cu + H_2SO_4 + O \longrightarrow CuSO_4 + H_2O \\ \hline \hline Cu + 2H_2SO_4 \longrightarrow CuSO_4 + SO_2 + 2H_2O \\ \hline H_2SO_4(\text{conc.}) \longrightarrow H_2O + SO_2 + O \\ \hline 2Ag + H_2SO_4 + O \longrightarrow Ag_2SO_4 + H_2O \\ \hline \hline 2Ag + 2H_2SO_4 \longrightarrow Ag_2SO_4 + SO_2 + 2H_2O \\ \hline 2HNO_3(\text{conc.}) \longrightarrow H_2O + 2NO_2 + O \\ \hline Cu + 2HNO_3 + O \longrightarrow Cu(NO_3)_2 + H_2O \\ \hline \hline Cu + 4HNO_3 \longrightarrow Cu(NO_3)_2 + 2NO_2 + 2H_2O \\ \hline 2HNO_3(\text{conc.}) \longrightarrow H_2O + 2NO_2 + O \\ \hline 2Ag + 2HNO_3 + O \longrightarrow 2AgNO_3 + H_2O \\ \hline \hline 2Ag + 4HNO_3 \longrightarrow 2AgNO_3 + 2NO_2 + 2H_2O \\ \hline 2HNO_3(\text{dil.}) \longrightarrow H_2O + 2NO + 3[O] \\ \hline [Cu + 2HNO_3 + O \longrightarrow Cu(NO_3)_2 + H_2O] \times 3 \\ \hline \hline 3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O \\ \hline 2HNO_3(\text{dil.}) \longrightarrow H_2O + 2NO + 3[O] \\ \hline [2Ag + 2HNO_3 + O \longrightarrow 2AgNO_3 + H_2O] \times 3 \\ \hline \hline 6Ag + 8HNO_3 \longrightarrow 6AgNO_3 + 2NO + 4H_2O \\ \hline 3Ag + 4HNO_3 \longrightarrow 3AgNO_3 + NO + 2H_2O \\ \hline Gold only dissolves in aqua-regia. \\ \hline [HNO_3 + 3HCl \longrightarrow NOCl + 2H_2O + 2Cl] \times 3 \\ \hline (conc.) & (conc.) \\ \hline (conc.) & HAUCl_4 \times 2 \\ \hline (conc.) & HAUCl_4 \times 2 \\ \hline (Au + 3Cl \longrightarrow AuCl_3] \times 2 \\ \hline (Au + 3HNO_3 + 1HCl \longrightarrow HAuCl_4 \times 3NOCl + 6H_2O \\ \hline Or & HNO_3 + 3HCl \longrightarrow NO + 2H_2O + 3Cl \\ \hline Au + HCl + 3Cl \longrightarrow HAuCl_4 \\ \hline Au + HNO_3 + 4HCl \longrightarrow HAuCl_4 + NO + 2H_2O \\ \hline \end{array}$$

or

or

- (g) Alloy formation: Copper, silver and gold readily form alloys with each other and with many other metals. They form amalgams with mercury.
- (h) Complex formation: These metals have strong tendency to form complex compounds. A variety of anionic and cationic complexes are formed. The principal coordination numbers are 2 or 4. Some complex compounds are listed below:

$K_3[Cu(CN)_4]$	$K[Ag(CN)_2]$	$K[Au(CN)_2]$
Pot. cuprocyanide	Pot argentocyanide	Pot. aurocyanide
$[Cu(NH_3)_4]SO_4$	Ag(NH <sub>3</sub> ) <sub>2</sub> Cl	K[AuCl <sub>4</sub> ]
Cuprammonium	Silver ammonium	Pot. auric chloride
sulphate	chloride	•

#### 5. Nature of Compounds

(a) Oxides: The monoxides of the type M<sub>2</sub>O are weakly basic. The basicity does not vary regularly in the group, Ag<sub>2</sub>O being most basic. These are insoluble in water. CuO shows basic nature while Au<sub>2</sub>O<sub>3</sub> shows acidic nature as it dissolves in strong alkalies.

$$\begin{array}{c} CuO + H_2SO_4 \longrightarrow CuSO_4 + H_2O \\ Au_2O_3 + 2NaOH \longrightarrow 2NaAuO_2 + H_2O \\ \hline Sodium aurate \end{array}$$

The oxides of silver and gold are thermally unstable. These can be easily reduced with reducing agents. The hydroxides are weak bases. The hydroxides of Ag and Au are unstable.

(b) Halides: Halides of Cu<sup>+</sup>, Ag<sup>+</sup> and Au<sup>+</sup> are insoluble in water except AgF. The halides of silver get decomposed in light. AgCl is soluble in ammonia solution. AgBr is partially soluble while AgI is insoluble.

$$AgCl + 2NH_4OH \longrightarrow Ag(NH_3)_2Cl + 2H_2O$$
Soluble

- (c) Sulphides: Cu, Ag and Au form sulphides, Cu<sub>2</sub>S, CuS; Ag<sub>2</sub>S; Au<sub>2</sub>S and Au<sub>2</sub>S<sub>3</sub>. Copper and silver sulphides are insoluble in ammonium sulphide but gold sulphides dissolve forming thioaurates.
- (d) Oxysalts: Copper forms stable oxysalts in divalent state while silver stable oxysalts are known in monovalent state. Gold does not form oxysalts. The oxysalts of copper and silver decomposes on heating.

$$CuCO_{3} \longrightarrow CuO + CO_{2}$$

$$Ag_{2}CO_{3} \longrightarrow 2Ag + CO_{2} + \frac{1}{2}O_{2}$$

$$Cu(NO_{3})_{2} \longrightarrow CuO + 2NO_{2} + \frac{1}{2}O_{2}$$

$$AgNO_{3} \longrightarrow Ag + NO_{2} + \frac{1}{2}O_{2}$$

$$CuSO_{4} \longrightarrow CuO + SO_{2} + \frac{1}{2}O_{2}$$

$$Ag_{2}SO_{4} \longrightarrow 2Ag + SO_{2} + O_{2}$$

## Similarities of Copper with Nickel and Zinc

## (1) Similarities with Nickel

- (i) Both are transition metals. These are hard, malleable and ductile. They have high melting and boiling points. They are good conductors of heat and electricity.
- (ii) Both the metals show variable valency. The stable valency is the divalency. Both form two series of salts: cuprous and cupric; nickelous and nickelic. Stable salts are cupric and nickelous (divalency). The salts are coloured—cupric salts are bluish and green while nickelous salts are green.
  - (iii) Their  $M^{2+}$  ions are similar in size.

$$Cu^{2+} = 0.69\text{Å} \text{ Ni}^{2+} = 0.72\text{Å}$$

- (iv) Both form black sulphides, CuS and NiS.
- (v) Both are acted upon by oxidising acids.
- (vi) Both form similar sulphates.

Both are soluble in water and form double sulphates of the type,  $(NH_4)_2SO_4\cdot MSO_4\cdot 6H_2O$ .

(vii) The oxides of both can be obtained by heating their carbonates or nitrates.

$$\begin{aligned} &\text{NiCO}_{3} \longrightarrow \text{NiO} + \text{CO}_{2} \\ &\text{CuCO}_{3} \longrightarrow \text{CuO} + \text{CO}_{2} \\ &\text{Ni(NO}_{3})_{2} \longrightarrow \text{NiO} + 2\text{NO}_{2} + \frac{1}{2}\text{O}_{2} \\ &\text{Cu(NO}_{3})_{2} \longrightarrow \text{CuO} + 2\text{NO}_{2} + \frac{1}{2}\text{O}_{2} \end{aligned}$$

CuO and NiO are basic in nature. These can be reduced with hydrogen.

- (viii) Basic carbonates of the general formula  $MCO_3 \cdot M(OH)_2$  are precipitated on treating their salts with sodium carbonate. Normal carbonates are obtained by using sodium bicarbonate.
- (ix) Both have a tendency to form complexes. They usually show coordination number 4.

- (x) Both of them show catalytic properties.
- (xi) Both form a number of alloys.

# (2) Similarities with Zinc

- (i) Both are metals.
- (ii) Both show divalency.
- (iii) Both form oxides of the type MO, i.e., CuO and ZnO. These can be obtained by heating their carbonates or nitrates.

$$ZnCO_3 \longrightarrow ZnO + CO_2$$
  
 $Zn(NO_3)_2 \longrightarrow ZnO + 2NO_2 + \frac{1}{2}O_2$ 

(iv) Both form similar compounds. Sulphides, phosphates and carbonates are insoluble in water while chlorides and sulphates are soluble in  $H_2O$ .

- (v) Both form hydrated sulphates,  $CuSO_4.5H_2O$  and  $ZnSO_4.7H_2O$ . They also form double sulphates of the type,  $(NH_4)_2SO_4.MSO_4.6H_2O$ .
  - (vi) Hydrated chlorides cannot be dehydrated by heating.

$$ZnCl_2 \cdot 2H_2O \longrightarrow Zn(OH)Cl + HCl + H_2O$$

(vii) Both have a tendency to form complexes.

 $\begin{aligned} & [Cu(NH_3)_4]SO_4 & & [Zn(NH_3)_4]SO_4 \\ & K_3[Cu(CN)_4] & & K_2[Zn(CN)_4] \end{aligned}$ 

- (viii) Both form a number of alloys.
- (ix) Basic carbonates of the general formula  $MCO_3 \cdot M(OH)_2$  are precipitated on treating their salts with sodium carbonate. Normal carbonates are obtained by using sodium bicarbonate.

# 14.15 COPPER

Copper has been known to mankind from prehistoric times. It was alloyed with other metals and the use of bronze in Egypt is reported as early as 350 B.C. Romans and Greeks obtained this metal from the island of Cyprus from which the name 'cuprum' was derived.

**Occurrence:** Copper constitutes only 0.0001 per cent of the earth's crust. Its deposits, however, are concentrated. Copper is found in nature in the following forms.

- 1. Native state: Copper is found in the metallic condition in large quantities near lake Superior in U.S.A.; in the Ural mountains (Russia) and Sweden.
- **2.** Combined state: The principal ores of copper are sulphides, oxides and basic carbonates.

## ■ Sulphide Ores

- (i) Chalcopyrites or copper pyrites, CuFeS<sub>2</sub>
- (ii) Chalcocite or copper glance, Cu<sub>2</sub>S
- (iii) Bornite, Cu<sub>3</sub>FeS<sub>3</sub>

#### Oxide Ore

Cuprite (red), Cu<sub>2</sub>O

#### ■ Basic Carbonates

- (i) Malachite (green), CuCO<sub>3</sub>·Cu(OH)<sub>2</sub>
- (ii) Azurite (blue), 2CuCO<sub>3</sub>·Cu(OH)<sub>2</sub>

Copper is found to a very minute extent in the animal body where it is said to catalyse the action of iron in the formation of haemoglobin. It is present in traces in the cereals and potatoes. It occurs as a red colouring matter of the feathers of certain birds. Milk has a very low copper content.

India is not rich in copper ores. Copper is found in India mainly in Singhbhum district (Jharkhand), Matigara and Dharwar. The copper belt in Rajasthan (Khetri) is at present under extensive development.

#### Extraction

Copper may be extracted by different methods depending upon the nature of the ore and the % of copper. The methods may be divided into two categories.

#### 1. From sulphide ores:

- (a) Dry process or smelting process: This is applied to those ores in which copper content is more than 3%.
- (b) Wet process or hydro-metallurgical process: This is applied to poor ores containing small percentage of copper.
  - 2. From non-sulphide ores: Leaching process.

**Dry process for the extraction of copper:** Copper is extracted mainly from copper pyrites by dry process or smelting process. The process of extraction of copper from copper pyrites involves the following steps:

(i) Concentration of the ore: The concentration of the sulphide ores is done by froth floatation process. The ores are powdered and sieved and then thrown into tanks of water to which pine oil and potassium xanthate have been added. A strong stream of air is passed which agitates the whole mass. Froth is produced which carries along the particles of the ore

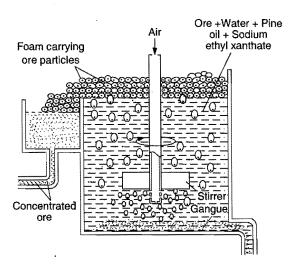

Fig. 14.8

to the surface of the liquid while the impurities settle to the bottom of the tank (Fig. 14.8). The froth is continuously separated. This is the concentrated ore.

- (ii) Roasting: The concentrated ore is heated strongly in a current of air on the hearth of the reverberatory furnace (Fig. 14.9). During roasting the following changes take place.
  - (a) Free sulphur is oxidised and removed as sulphur dioxide.

$$S + O_2 \longrightarrow SO_2$$

(b) The arsenic and antimony present in the ore are removed as volatile oxides.

$$4As + 3O_2 \longrightarrow 2As_2O_3$$

$$4Sb + 3O_2 \longrightarrow 2Sb_2O_3$$

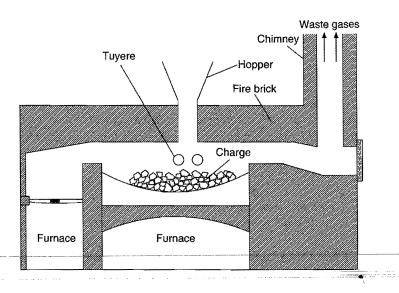

Fig. 14.9

(c) The pyrite is converted into cuprous sulphide and ferrous sulphide with evolution of sulphur dioxide.

$$2CuFeS_2 + O_2 \longrightarrow Cu_2S + 2FeS + SO_2$$

(d) The sulphides of copper and iron are partially oxidised.

$$2FeS + 3O_2 \longrightarrow 2FeO + 2SO_2$$
  
 $2Cu_2S + 3O_2 \longrightarrow 2Cu_2O + 2SO_2$ 

(iii) **Smelting:** The roasted ore is mixed with coke and silica and transferred to a small blast furnace (Fig. 14.10). The

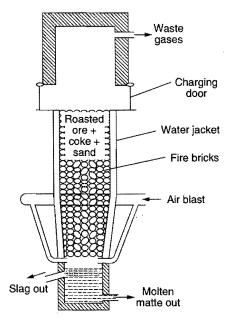

Fig. 14.10

mixture is heated in the presence of excess of air. The modern blast furnace is made of steel lined inside with refractory bricks and is about 15 to 20 feet in height. It is water jacketed throughout and is provided near the top with a waste gas outlet.

The air blast enters the furnace through tuyeres. The following changes occur in the blast furnace.

(a) The cuprous oxide reacts with ferrous sulphide.

$$FeS + Cu_2O \longrightarrow FeO + Cu_2S$$

[Iron has greater affinity for oxygen than copper. The copper oxide formed reacts with unchanged iron sulphide to form iron oxide and reproduce copper sulphide. So it is difficult to oxidise cuprous sulphide until whole of the iron sulphide is oxidised].

- (b) Most of the iron sulphide is oxidised to ferrous oxide.  $2\text{FeS} + 3\text{O}_2 \longrightarrow 2\text{FeO} + 2\text{SO}_2$
- (c) Ferrous oxide combines with silica and forms ferrous silicate. By this reaction most of the iron is removed as slag.

$$\frac{\text{FeO} + \text{SiO}_2 \longrightarrow \text{FeSiO}_3}{\text{Ferrous silicate}}$$

The lowest point of the furnace consists of a shallow hearth in which the molten mass collects which is known as 'Matte'. The matte contains mostly cuprous sulphide with a little iron sulphide.

**(iv)** Bessemerisation: The matte obtained from smelting is transferred to a Bessemer converter. Some sand (silica) is added and a blast of air is blown through the molten mass. The Bessemer converter is usually a pear shaped steel vessel lined with magnesite and quartz. It is fitted with air-blast tuyeres and mounted in such a way that it can be tilted in the desired direction (Fig. 14.11).

The following reactions occur in the Bessemer converter.

(a) Remaining ferrous sulphide gets oxidised.

 $2FeS + 3O_2 \longrightarrow 2FeO + 2SO_2$ 

Fig. 14.11

Molten matte + Sand

(b) Ferrous oxide combines with silica to form slag which is drained out at intervals by tilting the vessel. In about three hours time, all the iron is removed as ferrous silicate.

$$FeO + SiO_2 \longrightarrow FeSiO_3$$
(Slag)

(c) The blast of air is continued for almost another two hours. Excess of silica is absorbed by basic lining of the con-

verter and part of cuprous sulphide is oxidised which combines with remaining cuprous sulphide to form free copper metal.

$$2Cu_2S + 3O_2 \longrightarrow 2Cu_2O + 2SO_2$$
  
 $Cu_2S + 2Cu_2O \longrightarrow 6Cu + SO_2$ 

This presents an example of auto-reduction.

The molten copper is poured off and allowed to cool. During cooling, the dissolved sulphur dioxide comes out and large blisters are formed on the surface. Hence, the metal formed is given the name 'blister copper'. Blister copper consists 98% copper and 2% impurities.

- (v) Refining: Blister copper is subjected to refining by either of the following two methods.
- (a) Refining by poling: The impure metal is melted in a reverberatory furnace lined with silica. A part of copper metal is oxidised to cuprous oxide which dissolves in the melt and supplies oxygen to the more basic elements contained in it as impurity. These oxides either volatilise or combine with silica forming slag. The oxide of copper which remains in the mass is reduced by introducing poles of green wood. The gas (hydrocarbons) bubbles originating from the wood act as reducing agents. The mass is stirred vigorously with these poles. The process is thus called poling.

This process produces copper of about 99.5% purity and is known as tough pitch copper.

**(b) Electrolytic refining:** Copper is usually refined electrolytically. The electrolytic bath consists about 15% copper sulphate solution having 5% sulphuric acid. The anodes are of blister copper and cathodes are thin sheets of pure copper (Fig. 14.12).

As the current flows, copper from anodes dissolves while pure copper is deposited on the cathodes.

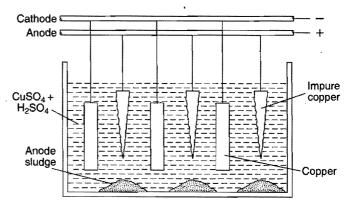

Fig. 14.12

$$CuSO_4 \rightleftharpoons Cu^{2+} + SO_4^{2-}$$
Cathode
$$Cu^{2+} + 2e \longrightarrow Cu$$

$$Cu + SO_4^{2-} \longrightarrow CuSO_4 + 2e$$

The more electropositive impurities like Fe, Zn, Ni, Co, etc., dissolve in the solution and less electropositive

impurities such as Ag, Au and Pt collect below the anode in the form of anodic mud. Electrolytic copper has a purity of 99.96–99.99%.

Wet process or Hydrometallurgical process: The essential principle of this process consists in the conversion of copper present in the ore into soluble copper compound and precipitation of copper by addition of iron or by electrolytic process.

Big heaps of copper sulphide ores are exposed to air and rain. Water is also sprayed at times, if necessary. After a year's time, the copper sulphide is slowly oxidised to copper sulphate. The liquor which flows from the bottom of the heaps is run into pans. Copper is precipitated from the liquor by the addition of scrap iron. The precipitate is dried, melted and refined.

$$2Cu_2S + 5O_2 \longrightarrow 2CuSO_4 + 2CuO$$
  
 $CuSO_4 + Fe \longrightarrow Cu + FeSO_4$   
(ppt.)

**2.** Extraction of copper from non-sulphide ores: The oxide and carbonate ores are crushed and concentrated by gravity process. The concentrated ores are calcined in reverberatory furnace. The carbonate decomposes to form the oxide and the impurities either volatilise or are oxidised.

$$CuCO_3 \cdot Cu(OH)_2 \longrightarrow 2CuO + CO_2 + H_2O$$

The oxide so formed is either reduced with carbon in reverberatory furnace or leached with dilute H<sub>2</sub>SO<sub>4</sub>.

$$\begin{array}{c} \text{CuO} + \text{C} & \longrightarrow \text{Cu} + \text{CO} \\ \text{Cu}_2\text{O} + \text{C} & \longrightarrow 2\text{Cu} + \text{CO} \\ \text{CuO} + \text{H}_2\text{SO}_4 & \longrightarrow \text{CuSO}_4 + \text{H}_2\text{O} \end{array}$$

FLOW SHEET FOR THE EXTRACTION OF COPPER Copper pyrites (CuFeS<sub>2</sub>) Crushed and sieved Concentration by froth floatation Powdered ore + water + pine oil + air - sulphide ore in the froth Roasting in reverberatory furnace in presence of air  $\begin{array}{c} S + O_2 \longrightarrow SO_2 \\ 4As + 3O_2 \longrightarrow 2As_2O_3 \end{array}$  $2\text{CuFeS}_2 + \text{O}_2 \longrightarrow \text{Cu}_2\text{S} + 2\text{FeS} + \text{SO}_2$ Silica + coke ----- Roasted ore Smelting in blast furnace in presence of air  $2FeS + 3O_2 \longrightarrow 2FeO + 2SO_2$  $FeO + SiO_2 \longrightarrow FeSiO_3$  (Slag)  $\xrightarrow{\text{Silica}}$  Matte (Cu<sub>2</sub>S, FeS) Bessemerisation in bessemer converter in presence of air  $\begin{array}{l} {\rm 2FeS} \, + \, {\rm 3O_2} \longrightarrow {\rm 2FeO} \, + \, {\rm 2SO_2} \\ {\rm FeO} \, + \, {\rm SiO_2} \longrightarrow {\rm FeSiO_3} \, \, ({\rm Slag}) \\ \end{array}$  $2Cu_2S + 3O_2 \longrightarrow 2Cu_2O + 2SO_2$  $2Cu_2O + Cu_2S \xrightarrow{Auto} 6Cu + SO_2$ 

Blister copper (98% Cu + 2% impurities)

Electrolytic refining
Anode–Impure copper plates
Cathode–Pure copper plates
Electrolyte–CuSO<sub>4</sub> soln. + H<sub>2</sub>SO<sub>4</sub>
Pure copper deposited at cathode

Pure copper (99.6–99.9%)

Copper sulphate solution obtained is then electrolysed using copper sheet as cathode and lead plate as anode. Copper can also be recovered by using scrap iron.

$$CuSO_4 + Fe \longrightarrow Cu + FeSO_4$$

### Properties

Physical: (a) It is a reddish coloured lustrous metal.

- (b) It is highly malleable and ductile.
- (c) It has specific gravity 8.9.
- (d) It has high melting and boiling points (m.pt. 1083°C, b.pt. 2580°C).
- (e) It is good conductor of heat and electricity (next to silver).
- (f) Its atomic radii is 1.17Å and ionisation potential is 7.72 eV.
- (g) Molten copper absorbs sulphur dioxide which it gives out on cooling.

**Chemical:** Copper is chemically less reactive as it has high heat of sublimation and high ionisation potential.

(a) Action of air and oxygen: Copper is not affected by dry air at ordinary temperatures but when exposed to air and moisture, it is covered by a green thin film which was formerly supposed to be the basic carbonate but consists of *bronchantite*, CuSO<sub>4</sub>·3Cu(OH)<sub>2</sub> or *atacamite*, CuCl<sub>2</sub>·3Cu(OH)<sub>2</sub> due to presence of SO<sub>2</sub> and HCl in the atmosphere.

$$8Cu + 6H2O + 2SO2 + 5O2 \longrightarrow 2[CuSO4·3Cu(OH)2]$$

$$2Cu + H2O + CO2 + O2 \longrightarrow CuCO3·Cu(OH)2$$
Basic carbonate

The layer protects the rest of the metal from further action. When heated in oxygen, it first forms red cuprous oxide (Cu<sub>2</sub>O) which changes into black cupric oxide (CuO). If the temperature is raised above 1100°C, cupric oxide changes back to cuprous oxide.

$$4Cu + O_2 \longrightarrow 2Cu_2O \text{ (red)}$$

$$2Cu_2O + O_2 \longrightarrow 4CuO \text{ (black)}$$

$$2CuO \xrightarrow{1100^{\circ}C} Cu_2O + \frac{1}{2}O_2$$

**(b)** Action of water: Water at ordinary temperature has no action on copper. However, when steam is passed over red hot copper, hydrogen is evolved.

$$Cu + H_2O \xrightarrow{\text{Red heat}} CuO + H_2$$

(c) Action of acids: Non-oxidising acids (HCl and dil.  $H_2SO_4$ ) do not have any effect on copper. However, they dissolve the metal in presence of air.

2Cu + 4HCl (dil. or conc.) + 
$$O_2 \longrightarrow 2CuCl_2 + 2H_2O$$
  
2Cu +  $2H_2SO_4$  (dil.) +  $O_2 \longrightarrow 2CuSO_4 + 2H_2O$ 

Copper is readily affected by oxidising acids (conc.  $H_2SO_4$ , dilute and conc.  $HNO_3$ .)

Conc.  $H_2SO_4$ :  $SO_2$  is evolved on heating.

$$H_2SO_4 \longrightarrow H_2O + SO_2 + O$$

$$Cu + O + H_2SO_4 \longrightarrow CuSO_4 + H_2O$$

$$Cu + 2H_2SO_4 \longrightarrow CuSO_4 + SO_2 + 2H_2O$$

**Dilute HNO<sub>3</sub>:** NO is evolved on heating.  

$$2HNO_3 \longrightarrow H_2O + 2NO + 3[O]$$

$$[Cu + 2HNO_3 + O \longrightarrow Cu(NO_3)_2 + H_2O] \times 3$$

$$3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 4H_2O$$

Conc. HNO<sub>3</sub>: NO<sub>2</sub> is evolved on heating.

$$2HNO_3 \longrightarrow H_2O + 2NO_2 + O$$

$$Cu + 2HNO_3 + O \longrightarrow Cu(NO_3)_2 + H_2O$$

$$Cu + 4HNO_3 \longrightarrow Cu(NO_3)_2 + 2NO_2 + 2H_2O$$

Copper metal reacts with hydrobromic acid (HBr) and hydroiodic acid forming complexes.

$$2Cu + 2HBr \longrightarrow 2CuBr + H_2$$
  
 $2CuBr + 2HBr \longrightarrow H_2[Cu_2Br_4]$ 

Copper plates are slowly attacked by acetic acid (vinegar) in presence of air to form basic copper acetate (verdigris).

**(d) Action of ammonia:** Copper is dissolved by aqueous ammonia in the presence of air or oxygen with the formation of a complex.

$$2Cu + 8NH_3 + 2H_2O + O_2 \longrightarrow 2[Cu(NH_3)_4](OH)_2$$

However, when ammonia gas is passed over red hot copper, the nitrogen is absorbed by the metal leaving hydrogen free.

**(e) Action of halogens :** Copper combines with halogens directly.

$$Cu + Cl_2 \xrightarrow{Heat} CuCl_2$$

$$Cu + Br_2 \xrightarrow{Heat} CuBr_2$$

$$Cu \, + \, I_2 \, \xrightarrow{Heat} \, Cu I_2$$

Moist chlorine rapidly attacks copper even at ordinary temperatures.

(f) As a reducing agent: Copper reduces oxides of nitrogen to elementary nitrogen and ferric ion to ferrous ion.

$$2Cu + 2NO \longrightarrow 2CuO + N_2$$

$$2Fe^{3+} + Cu \longrightarrow 2Fe^{2+} + Cu^{2+}$$

The etching of designs on copper plates using ferric chloride is based on this property.

$$2FeCl_3 + Cu \longrightarrow CuCl_2 + 2FeCl_2$$

(g) Displacement reactions: Copper displaces Ag, Au and platinum metals from their salt solutions.

$$2AgNO_3 + Cu \longrightarrow 2Ag + Cu(NO_3)_2$$
  
 $3Cu + 2AuCl_3 \longrightarrow 3CuCl_2 + 2Au$ 

#### Uses

Copper is most useful metal (only next to iron) on account of its properties as it is stable in air and water and good conductor of heat and electricity.

It is used,

- (i) in the manufacture of electrical wires, cables, etc.
- (ii) for making vacuum pans, heating utensils, calorimeters, etc.
  - (iii) for electroplating and electrotyping.
  - (iv) for making coins, ornaments and jewellery.
- (v) for making various compounds which are used as insecticides, pesticides and pigments.
- (vi) for making a large number of alloys. The important alloys are listed below:

Alloy	Composition	Uses
(a) Brass	Cu 60–80%, Zn 40–20%	Domestic utensils, condensers, cartridges
(b) Bronze	Cu 75–90%, Sn 25–10%	cases, etc. Coins, statues, utensils, machine parts, bells, etc.
(c) German silver	Cu 56%, Zn 24%, Ni 20%	Utensils, ornaments, resistance coils.
(d) Gun metal	Cu 87%, Sn 10%, Zn 3%	Machine parts, guns.
(e) Rolled gold	Cu 95%, Al 5%	Artificial jewellery.
(f) Constantan	Cu 60%, Ni 40%	Electrical resistances.
(g) Monel metal	Cu 30%, Ni 67%, Fe 3%	Chemical plants, automobile engine parts.
(h) Phosphorus bronze	Cu 85%, Sn 13%, P 2%	Gears, aerials, propellers, etc.

# 14.16 COMPOUNDS OF COPPER

## Copper Forms two Series of Compounds

1. Cuprous compounds: In which copper is monovalent. Most of the cuprous compounds are colourless and diamagnetic as 3d-shell is completely filled.  $Cu_2O$  and  $Cu_2S$  are red and black, respectively, which are exceptions. Cuprous compounds are generally insoluble in water. The soluble compounds are unstable in aqueous solutions, since they disproportionate to  $Cu^{2+}$  and Cu.

$$2Cu^+ \longrightarrow Cu^{2+} + Cu$$

Cuprous compounds can be obtained by passing sulphur dioxide through a solution containing copper sulphate and sodium salt. Some examples are given below:

(i) 
$$2\text{CuSO}_4 + 2\text{NaCl} + \text{SO}_2 + 2\text{H}_2\text{O} \longrightarrow \\ 2\text{CuCl} + \text{Na}_2\text{SO}_4 + 2\text{H}_2\text{SO}_4 \\ \text{Cuprous chloride}$$

(ii) 
$$2\text{CuSO}_4 + 2\text{NaBr} + \text{SO}_2 + 2\text{H}_2\text{O} \longrightarrow \\ 2\text{CuBr} + \text{Na}_2\text{SO}_4 + 2\text{H}_2\text{SO}_4 \\ \text{Cuprous bromide}$$

(iii) 
$$2\text{CuSO}_4 + 2\text{NaI} + \text{SO}_2 + 2\text{H}_2\text{O} \longrightarrow \\ 2\text{CuI} + \text{Na}_2\text{SO}_4 + 2\text{H}_2\text{SO}_4 \\ \text{Cuprous iodide}$$

(iv) 
$$2\text{CuSO}_4 + 2\text{NaCN} + \text{SO}_2 + 2\text{H}_2\text{O} \longrightarrow \\ 2\text{CuCN} + \text{Na}_2\text{SO}_4 + 2\text{H}_2\text{SO}_4 \\ \text{Cuprous cyanide}$$

(v) 
$$2\text{CuSO}_4 + 2\text{NaCNS} + \text{SO}_2 + 2\text{H}_2\text{O} \longrightarrow \\ 2\text{CuCNS} + \text{Na}_2\text{SO}_4 + 2\text{H}_2\text{SO}_4 \\ \text{Cuprous thiocyanate}$$

The reactions (iii) and (iv) can take place even in absence of sulphur dioxide.

$$2\text{CuSO}_4 + 4\text{NaI} \longrightarrow 2\text{CuI} + 2\text{Na}_2\text{SO}_4 + \text{I}_2$$
  
 $2\text{CuSO}_4 + 4\text{NaCN} \longrightarrow 2\text{CuCN} + 2\text{Na}_2\text{SO}_4 + (\text{CN})_2$ 

The true molecular formula of cuprous compounds is still doubtful. There are experimental evidences for dimeric molecule.

## Cuprous Chloride, Cu<sub>2</sub>Cl<sub>2</sub>

## **■** Preparation

It is prepared—

(i) by heating excess of copper with concentrated hydrochloric acid in presence of a little potassium chlorate.

$$\begin{aligned} Cu + 2HCl + O &\longrightarrow CuCl_2 + H_2O \\ CuCl_2 + Cu &\longrightarrow Cu_2Cl_2 \end{aligned}$$

(ii) by boiling copper sulphate solution with excess of copper turnings in presence of hydrochloric acid.

$$\begin{aligned} \text{CuSO}_4 + 2\text{HCl} &\longrightarrow \text{CuCl}_2 + \text{H}_2\text{SO}_4 \\ \text{CuCl}_2 + \text{Cu} &\longrightarrow \text{Cu}_2\text{Cl}_2 \end{aligned}$$

(iii) by heating cupric chloride with zinc or sulphur dioxide.

$$2CuCl_2 + Zn \longrightarrow Cu_2Cl_2 + ZnCl_2$$
 
$$2CuCl_2 + 2H_2O + SO_2 \longrightarrow Cu_2Cl_2 + 2HCl + H_2SO_4$$

(iv) by passing SO<sub>2</sub> through the solution containing copper sulphate and sodium chloride.

$$2CuSO4 + 2NaCl + 2H2O + SO2 \longrightarrow Cu2Cl2 + Na2SO4 + 2H2SO4$$

### Properties

(i) It is a white solid. It is insoluble in water but soluble in excess of hydrochloric acid.

$$Cu_2Cl_2 + 4HCl \longrightarrow 2H_2CuCl_3$$
 or 
$$Cu_2Cl_2 + 6HCl \longrightarrow 2H_3CuCl_4$$

The solution again gives a white precipitate on dilution.

(ii) It gradually turns green on exposure in air due to oxidation.

$$2Cu_2Cl_2 + 2H_2O + O_2 \longrightarrow 2[CuCl_2 \cdot Cu(OH)_2]$$
 Basic cupric chloride

(iii) The solution of cuprous chloride in HCl is oxidised by air or oxidising agents into cupric chloride.

$$Cu_2Cl_2 + 2HCl + \frac{1}{2}O_2 \longrightarrow 2CuCl_2 + H_2O$$

(iv) The solution of cuprous chloride in HCl absorbs carbon monoxide and forms an addition compound.

$$Cu_2Cl_2 + 2CO \longrightarrow 2CuCl\cdot CO$$

The addition compound decomposes on heating evolving carbon monoxide. The reaction is utilised for the removal of carbon monoxide.

- (v) It dissolves in aqueous ammonia forming a colourless solution due to the formation of the complex Cu(NH<sub>3</sub>)<sub>2</sub>Cl.
- (vi) The ammonical cuprous chloride solution absorbs acetylene to form bright red precipitate of cuprous acetylide,  $Cu_2C_2$ .

$$2Cu(NH_3)_2Cl + C_2H_2 \longrightarrow Cu_2C_2 + 2NH_3 + 2NH_4Cl$$

Acetylene can be regenerated by treating the acetylide with strong HCl. The reaction is, therefore, used for the purification and separation of acetylene.

$$Cu_2C_2 + 2HCl \longrightarrow C_2H_2 + Cu_2Cl_2$$

(vii) Cuprous chloride with caustic alkalies gives a yellow precipitate of cuprous oxide which gradually changes to red.

$$\begin{array}{c} Cu_2Cl_2 + 2NaOH \longrightarrow & Cu_2O \\ & & Yellow \ changing \\ & to \ red \end{array} + 2NaCl + H_2O \\$$

(viii) With H<sub>2</sub>S, cuprous chloride forms a black precipitate of cuprous sulphide.

$$Cu_2Cl_2 + H_2S \longrightarrow Cu_2S + 2HCl$$

(ix) With sodium chloride or potassium chloride solution cuprous chloride forms a soluble complex.

$$Cu_2Cl_2 + 6NaCl \longrightarrow 2Na_3CuCl_4$$
  
 $Cu_2Cl_2 + 6KCl \longrightarrow 2K_3CuCl_4$ 

(x) Dry cuprous chloride forms addition compounds with ammonia gas of the formula CuCl·nNH $_3$  where  $n=1,\,1\frac{1}{2}$ , 3.

$$Cu_2Cl_2 + 2NH_3 \longrightarrow 2CuCl \cdot NH_3$$

#### Uses

- (i) Ammonical solution of cuprous chloride is used for absorbing acetylene.
- (ii) HCl solution of cuprous chloride is used for absorption of carbon monoxide.
  - (iii) It is also used for absorption of ammonia gas.
- (iv) It is used as a catalyst in **Deacon's** process for the manufacture of chlorine gas.
- **2. Cupric compounds:** In which copper is divalent, cupric compounds are more stable, more common and generally more stable. Most of the *anhydrous cupric compounds* are colourless while the hydrated compounds are generally blue due to the

formation of blue hydrated ion,  $[Cu(H_2O)_4]^{2+}$  or  $[Cu(H_2O)_6]^{2+}$ . Compounds of  $Cu^{2+}$  ions are paramagnetic due to presence of one unpaired electron in 3d energy shell, *i.e.*, configuration of  $Cu^{2+}$  is  $3d^9$ . Some important cupric compounds are described here.

## Cupric Oxide, CuO

It is called black oxide of copper and is found in nature as tenorite.

## Preparation

It is prepared—

(i) by heating Cu<sub>2</sub>O in air or by heating copper for a long time in air (the temperature should not exceed above 1100°C).

$$Cu_2O + \frac{1}{2}O_2 \longrightarrow 2CuO$$

$$2Cu + O_2 \longrightarrow 2CuO$$

(ii) by heating cupric hydroxide,

$$Cu(OH)_2 \longrightarrow CuO + H_2O$$

(iii) by heating copper nitrate,

$$2Cu(NO_3)_2 \longrightarrow 2CuO + 4NO_2 + O_2$$

(iv) on a commercial scale, it is obtained by heating malachite which is found in nature.

$$CuCO_3 \cdot Cu(OH)_2 \longrightarrow 2CuO + CO_2 + H_2O$$

## Properties

- (a) It is black powder and stable to moderate heating.
- (b) The oxide is insoluble in water but dissolves in acids forming corresponding salts.

$$\begin{array}{c} \text{CuO} + 2\text{HCl} \longrightarrow \text{CuCl}_2 + \text{H}_2\text{O} \\ \text{CuO} + \text{H}_2\text{SO}_4 \longrightarrow \text{CuSO}_4 + \text{H}_2\text{O} \\ \text{CuO} + 2\text{HNO}_3 \longrightarrow \text{Cu(NO}_3)_2 + \text{H}_2\text{O} \end{array}$$

(c) When heated to 1100–1200°C, it is converted into cuprous oxide with evolution of oxygen.

$$4CuO \longrightarrow 2Cu_2O + O_2$$

(d) It is reduced to metallic copper by reducing agents like hydrogen, carbon and carbon monoxide.

$$\begin{array}{c} CuO + H_2 \longrightarrow Cu + H_2O \\ CuO + C \longrightarrow Cu + CO \\ CuO + CO \longrightarrow Cu + CO_2 \end{array}$$

#### **Uses**

It is used to impart green to blue colour to glazes and glass. It is used in organic analysis for the estimation and detection of carbon. It is also used in petroleum for the removal of sulphur.

## Cupric Chloride, CuCl<sub>2</sub>·2H<sub>2</sub>O

### Preparation

(i) The metal or cupric oxide or cupric hydroxide or copper carbonate is dissolved in conc. HCl. The resulting solution on crystallisation gives green crystals of hydrated cupric chloride.

$$2Cu + 4HCl + O_2 \longrightarrow 2CuCl_2 + 2H_2O$$

$$CuO + 2HCl \longrightarrow CuCl_2 + H_2O$$

$$Cu(OH)_2CuCO_3 + 4HCl \longrightarrow 2CuCl_2 + 3H_2O + CO_2$$

(ii) Anhydrous cupric chloride is obtained as a dark brown mass when copper metal is heated in excess of chlorine gas or by heating hydrated cupric chloride in HCl gas at 150°C.

$$Cu + Cl_2 \longrightarrow CuCl_2$$

$$CuCl_2 \cdot 2H_2O \xrightarrow{150^{\circ}C} CuCl_2 + 2H_2O$$

### Properties

- (i) It is a deliquescent compound and is readily soluble in water. The dilute solution is blue but concentrated solution is, however, green. It changes to yellow when conc. HCl is added. The blue colour is due to complex cation  $[Cu(H_2O)_4]^{2+}$  and yellow colour due to complex anion  $[CuCl_4]^{2-}$  and green when both are present.
  - (ii) The aqueous solution is acidic due to its hydrolysis.

$$CuCl_2 + 2H_2O \rightleftharpoons Cu(OH)_2 + 2HCl$$

(iii) The anhydrous salt on heating forms Cu<sub>2</sub>Cl<sub>2</sub> and Cl<sub>2</sub>.

$$2CuCl_2 \longrightarrow Cu_2Cl_2 + Cl_2$$

while the hydrated salt on strong heating gives CuO,  $Cu_2Cl_2$ , HCl and  $Cl_2$ .

$$3CuCl_2 \cdot 2H_2O \longrightarrow CuO + Cu_2Cl_2 + 2HCl + Cl_2 + 5H_2O$$

(iv) It is readily reduced to Cu<sub>2</sub>Cl<sub>2</sub> by copper turnings, or SO<sub>2</sub> gas, or hydrogen (Nascent-obtained by the action of HCl on Zn) or SnCl<sub>2</sub>.

$$\begin{aligned} & \text{CuCl}_2 + \text{Cu} \longrightarrow \text{Cu}_2\text{Cl}_2 \\ 2\text{CuCl}_2 + \text{SO}_2 + 2\text{H}_2\text{O} \longrightarrow \text{Cu}_2\text{Cl}_2 + 2\text{HCl} + \text{H}_2\text{SO}_4 \\ 2\text{CuCl}_2 + 2\text{H} \longrightarrow \text{Cu}_2\text{Cl}_2 + 2\text{HCl} \\ 2\text{CuCl}_2 + \text{SnCl}_2 \longrightarrow \text{Cu}_2\text{Cl}_2 + \text{SnCl}_4 \end{aligned}$$

(v) A pale blue precipitate of basic cupric chloride, CuCl<sub>2</sub>·3Cu(OH)<sub>2</sub> is obtained when NaOH is added.

$$CuCl_2 + 2NaOH \longrightarrow Cu(OH)_2 + 2NaCl$$
  
 $CuCl_2 + 3Cu(OH)_2 \longrightarrow CuCl_2 \cdot 3Cu(OH)_2$ 

It dissolves in ammonium hydroxide forming a deep blue solution. On evaporating of this solution deep blue crystals of tetrammine cupric chloride are obtained.

$$CuCl_2 + 4NH_4OH \longrightarrow Cu(NH_3)_4Cl_2\cdot H_2O + 3H_2O$$

#### Uses

It is used as a catalyst in Deacon's process. It is also used in medicines and as an oxygen carrier in the preparation of organic dyestuffs.

## Copper Sulphate (Blue Vitriol), CuSO<sub>4</sub>·5H<sub>2</sub>O

Copper sulphate is the most common compound of copper. It is called as *blue vitriol* or *nila thotha*.

### Preparation

(i) Copper sulphate is prepared in the laboratory by dissolving cupric oxide or hydroxide or carbonate in dilute sulphuric acid. The solution is evaporated and crystallised.

$$CuO + H2SO4 \longrightarrow CuSO4 + H2O$$

$$Cu(OH)2 + H2SO4 \longrightarrow CuSO4 + 2H2O$$

$$Cu(OH)2CuCO3 + 2H2SO4 \longrightarrow 2CuSO4 + 3H2O + CO2$$

(ii) On a commercial scale, it is prepared from scrap copper. The scrap copper is placed in a perforated lead bucket which is dipped into hot dilute sulphuric acid. Air is blown through the acid. Copper sulphate is crystallised from the solution.

$$Cu + H_2SO_4 + \frac{1}{2}O_2(air) \longrightarrow CuSO_4 + H_2O$$

## Properties

- (a) It is a blue crystalline compound and is fairly soluble in water.
- (b) Heating effect: CuSO<sub>4</sub>·5H<sub>2</sub>O crystals effloresce on exposure and converted into a pale blue powder, CuSO<sub>4</sub>·3H<sub>2</sub>O. When heated to 100°C, bluish white monohydrate CuSO<sub>4</sub>·H<sub>2</sub>O is formed. The monohydrate loses last molecule of water at 230°C giving the anhydrous salt, CuSO<sub>4</sub>, which is white.

Anhydrous copper sulphate (white) regains its blue colour when moistened with a drop of water (test of water).

If the anhydrous salt is heated at 720°C, it decomposes into cupric oxide and sulphur trioxide.

$$\begin{array}{c} \text{CuSO}_4 \xrightarrow{\phantom{-}720^{\circ}\text{C}} \text{CuO} + \text{SO}_3 \\ \downarrow \\ \text{SO}_2 + \frac{1}{2}\text{O}_2 \end{array}$$

(c) Action of NH<sub>4</sub>OH: With ammonia solution, it forms the soluble blue complex. First it forms a precipitate of Cu(OH)<sub>2</sub> which dissolves in excess of ammonia solution.

$$\begin{array}{c} CuSO_4 + 2NH_4OH \longrightarrow Cu(OH)_2 + (NH_4)_2SO_4 \\ Cu(OH)_2 + 2NH_4OH + (NH_4)_2SO_4 \longrightarrow Cu(NH_3)_4SO_4 + 4H_2O \\ & \text{Tetrammine cupric} \\ & \text{sulphate} \end{array}$$

The complex is known as Schwitzer's reagent which is used for dissolving cellulose in the manufacture of artificial silk.

(d) Action of alkalies: Alkalies form a pale blue precipitate of copper hydroxide.

$$CuSO_4 + 2NaOH \longrightarrow Cu(OH)_2 + Na_2SO_4$$

(e) Action of potassium iodide: First cupric iodide is formed which decomposes to give white cuprous iodide and iodine.

$$[CuSO_4 + 2KI \longrightarrow CuI_2 + K_2SO_4] \times 2$$

$$2CuI_2 \longrightarrow Cu_2I_2 + I_2$$

$$2CuSO_4 + 4KI \longrightarrow Cu_2I_2 + 2K_2SO_4 + I_2$$

(f) Action of potassium cyanide: First cupric cyanide is formed which decomposes to give cuprous cyanide and cyanogen gas. Cuprous cyanide dissolves in excess of potassium cyanide to form a complex, potassium cupro cyanide [K<sub>3</sub>Cu(CN)<sub>4</sub>].

$$[CuSO_4 + 2KCN \longrightarrow Cu(CN)_2 + K_2SO_4] \times 2$$

$$2Cu(CN)_2 \longrightarrow Cu_2(CN)_2 + (CN)_2$$

$$Cu_2(CN)_2 + 6KCN \longrightarrow 2K_3Cu(CN)_4$$

$$2CuSO_4 + 10KCN \longrightarrow 2K_3Cu(CN)_4 + 2K_2SO_4 + (CN)_2$$

(g) Action of potassium ferrocyanide: Reddish brown precipitate of cupric ferrocyanide is formed. (test of Cu<sup>2+</sup> ion)

$$2\text{CuSO}_4 + \text{K}_4\text{Fe}(\text{CN})_6 \longrightarrow \text{Cu}_2\text{Fe}(\text{CN})_6 + 2\text{K}_2\text{SO}_4$$

(h) Addition of electropositive metals: Electropositive elements like zinc and iron precipitate copper from a solution of copper sulphate.

$$CuSO_4 + Fe \longrightarrow Cu + FeSO_4$$
  
 $CuSO_4 + Zn \longrightarrow Cu + ZnSO_4$ 

(i) Action of  $H_2S$ : When  $H_2S$  is passed through copper sulphate solution, a black precipitate of copper sulphide is formed.

$$CuSO_4 + H_2S \longrightarrow CuS + H_2SO_4$$

The black precipitate dissolves in conc. HNO<sub>3</sub>.

$$3\text{CuS} + 8\text{HNO}_3 \longrightarrow 3\text{Cu(NO}_3)_2 + 2\text{NO} + 3\text{S} + 4\text{H}_2\text{O}$$

(j) Action of potassium sulphocyanide: Cupric sulphocyanide is formed.

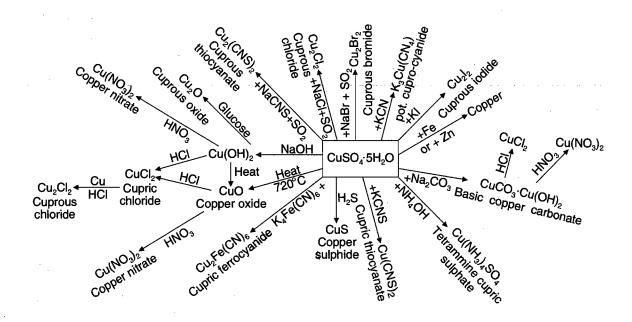

$$CuSO_4 + 2KCNS \longrightarrow Cu(CNS)_2 + K_2SO_4$$

If SO<sub>2</sub> is passed through the solution, a white precipitate of cuprous sulphocyanide is formed.

$$2\text{CuSO}_4 + 2\text{KCNS} + \text{SO}_2 + 2\text{H}_2\text{O} \longrightarrow \text{Cu}_2(\text{CNS})_2 + \text{K}_2\text{SO}_4 + 2\text{H}_2\text{SO}_4$$

[This is the general method for obtaining cuprous compounds.]

(k) **Double sulphates:** Copper sulphate forms double salts with alkali sulphate  $K_2SO_4$ ·Cu $SO_4$ ·6H $_2O$  and with ammonium sulphate as  $(NH_4)_2SO_4$ ·Cu $SO_4$ ·6H $_2O$ .

PROPERTIES OF COPPER SULPHATE AND PREPARATION OF VARIOUS COPPER COMPOUNDS

(1) Action of sodium thiosulphate: Sodium thiosulphate reacts with copper sulphate to form cupric thiosulphate which is reduced by sodium thiosulphate. The cuprous compound thus formed dissolves in excess of sodium thiosulphate to form a complex.

#### **■** Uses

- (i) Copper sulphate is used for the preparation of other copper compounds.
- (ii) It finds use in electroplating, electrotyping, calicoprinting and dyeing.
- (iii) It is used in agriculture as a fungicide and germicide.

  Bordeaux mixture consisting copper sulphate and lime is used to kill moulds and fungi on vines, trees, potatoes, etc.
- (iv) It is used as a laboratory reagent especially in the preparation of Fehling's solution.
  - (v) It finds use as an antiseptic in medicine.
  - (vi) It is extensively used in electric batteries.

# 14.17 SILVER

**Occurrence:** Silver is a rare element as it forms only  $10^{-8}$  per cent of the earth's crust. However, it was known in prehistoric times and used for its colour and beauty as a precious metal. Silver is found in nature in two forms.

#### 1. Native State

It occurs in the metallic condition usually associated with copper, gold and platinum metals. Native silver has been reported in a few places in Canada, United States of America, Mexico and Peru.

#### 2. Combined State

The important ores of silver are:

- (a) In the form of sulphide:
- (i) Argentite or silver glance, Ag<sub>2</sub>S
- (ii) Pyrargyrite or Ruby silver, 3Ag<sub>2</sub>S·Sb<sub>2</sub>S<sub>3</sub>
- (iii) Stromeyerite or silver copper glance, (Cu, Ag)<sub>2</sub>S
- (iv) Silver is also associated in the form of Ag<sub>2</sub>S in the lead ore, galena (PbS). The lead extracted usually contains silver and called argentiferous lead. Silver is recovered before lead is put into use.

#### (b) In the form of halide:

Chlorargyrite or Horn silver, AgCl.

In India, it occurs mainly as Ag<sub>2</sub>S associated with lead and zinc ores at Bawdivin and also associated with gold, in the native gold ores of Kolar. From these, silver is obtained as a

by-product but no workable deposits of silver are found in India

The ores of silver are usually associated with large amounts of rock, silica and clay. The silver content hardly exceeds 1.0 per cent. Most of the silver (nearly four-fifth of the total production) is obtained from argentiferous lead and from the anodic mud formed during electrolytic refining of copper. Thus, silver is obtained from the following sources.

- (i) From the ores of silver
- (ii) From native silver
- (iii) From argentiferous lead
- (iv) From the anodic mud in copper refining.

# 2 1. Extraction of silver from argentite ore (Cyanide process)

Cyanide process is the modern process for the extraction of silver. The process is also called as Mac-Arthur and Forest process. It is based on two points.

- (i) Silver compounds (or even free silver) dissolve in sodium cyanide solution forming a complex salt, NaAg(CN)<sub>2</sub>, in presence of air.
- (ii) Silver is precipitated from this complex salt by the addition of zinc.

The process involves the following steps:

- (i) Concentration of the ore: Concentration of the ore is done by froth floatation process. The ore is crushed and taken in a tank filled with water to which pine oil and potassium xanthate have been added. The whole mixture is agitated by passing a strong stream of air. The ore particles come to the surface alongwith froth while silicious impurities settle to the bottom.
- (ii) Cyanidation: The concentrated ore is ground to a very fine powder in ball mill. The finely powdered ore is treated with dilute solution (0.4 to 0.6%) of sodium cyanide and a current of air is blown through the whole mass. The silver present in the ore dissolves in the solution slowly to form sodium argentocyanide.

$$Ag_2S + 4NaCN \rightleftharpoons 2NaAg(CN)_2 + Na_2S$$

The above reaction is reversible. The air which is blown in serves an important function in removing sodium sulphide from the equilibrium mixture and causing the reaction to proceed in the desired direction.

$$4Na_2S + 5O_2 + 2H_2O \longrightarrow 2Na_2SO_4 + 4NaOH + 2S$$

The soluble sodium argentocyanide is removed by filtration. [Metallic silver and silver chloride (Horn silver) also dissolve in sodium cyanide solution.

$$4Ag + 8NaCN + 2H_2O + O_2 (air) \longrightarrow 4NaAg(CN)_2 + 4NaOH$$

$$AgCl + 2NaCN \longrightarrow NaAg(CN)_2 + NaCl]$$

(iii) **Recovery of silver:** Silver is precipitated from the solution by addition of zinc powder in a finely divided condition.

Silver is precipitated as a dark amorphous mass while zinc goes into the complex.

2NaAg(CN)<sub>2</sub> + Zn 
$$\longrightarrow$$
 Na<sub>2</sub>Zn(CN)<sub>4</sub> + 2Ag
Sodium zinco-
cvanide

[Zinc is more electropositive than silver.]

The precipitated silver is removed by filtration, dried and fused with potassium nitrate in a crucible in furnace. The impurities are oxidised and rise as a scum on the surface. Liquid silver on cooling appears as compact mass.

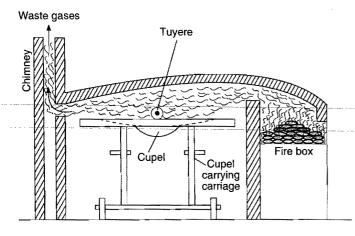

Fig. 14.13

- (iv) **Refining:** The main impurities are of lead, copper and gold. These are removed by following methods.
- (a) Cupellation process: Cupel is a big oval dish with a shallow hearth and is made of bone-ash or porous cement. The impure silver is fused on the hearth of the cupellation furnace and a strong current of air is blown over it.

Lead is oxidised to lead oxide (Litharge: PbO) which is blown away by air. Other impurities are also oxidised and rise to the surface and removed as scum. The oxides may also be absorbed by the lining of the cupel. The completion of the process is indicated by the appearance of bright shining surface of the molten silver.

(b) Electrolytic process: The impure silver is made as anode and pure silver plate as cathode. The electrolytic solution is of silver nitrate containing 10% nitric acid. On passing electric current silver ions start depositing on cathode and equivalent amount from anode comes into solution. In this way silver is transferred from anode to cathode. Copper goes into solution as copper nitrate while gold collects below the anode as anodic mud.

## 2. Amalgamation process

This is the old method of extraction. It is still in use in some countries. The sulphide ore is crushed and converted into a slime with a solution of cupric chloride.

$$Ag_2S + CuCl_2 \longrightarrow 2AgCl + CuS$$

Some mercury is then added to the product. Silver chloride reacts with mercury liberating silver.

$$2AgCl + 2Hg \longrightarrow 2Ag + Hg_2Cl_2$$

#### FLOW SHEET FOR THE EXTRACTION OF SILVER

Silver ore (Argentite)

**CYANIDATION** 

Concentrated ore + NaCN solution (0.4-0.6%) + Air  $Ag_2S + 4NaCN \implies 2NaAg(CN)_2 + Na_2S$  $4Na_2S + 5O_2 + 2H_2O \longrightarrow 2Na_2SO_4 + 4NaOH + 2S$ 

↓ Filtrate

PRECIPITATION OF SILVER WITH ZINC  $2NaAg(CN)_2 + Zn \longrightarrow 2Ag + Na_2Zn(CN)_4$  Black ppt.

Black ppt. of Ag + KNO<sub>3</sub>  $\xrightarrow{\text{Fuse}}$  Compact mass (Silver metal)

#### **ELECTROLYTIC REFINING**

Anode: Impure silver
Cathode: Pure silver plate

Electrolyte: AgNO<sub>3</sub> solution + HNO<sub>3</sub> Pure silver deposited on the cathode

The silver dissolves in excess of mercury to form an amalgam. It is washed and then distilled when silver is left behind in the retorts.

# 3. Extraction of silver from argentiferous lead (Desilverisation of lead)

Lead ores, especially galena, contain a very small percentage of silver sulphide. During the extraction of lead, silver remains in the metal. On account of its high value, silver is removed from the lead before it is used for any purpose. The crude lead contains upto 2% of silver. This poor amount of silver requires to be concentrated before desilverisation. The recovery of silver from crude lead (argentiferous lead), thus involves two steps:

- (i) Partial separation of lead (a) by Pattinson's process or(b) by Parkes process.
- (ii) Removal of lead as lead oxide by cupellation process.
- (a) Pattinson's process: This process is based on the fact that silver-lead system has an eutectic mixture with 2.6% silver melting at 303°C whereas pure lead melts at 327°C.

When the molten argentiferous lead is allowed to cool slowly, crystals of pure lead are deposited until the silver content of the mixture has risen to 2.6%. The crystals of pure lead are removed with the help of perforated ladles. The alloy rich in silver content is then subjected to cupellation to remove the remaining lead.

- **(b) Parkes process:** This is at present the most commonly used method. It depends on the following points:
  - (i) Zinc and lead are not miscible.
  - (ii) Silver is more miscible with zinc than lead.
- (iii) Zinc-silver alloy is lighter than molten lead and have a higher melting point.

Lead containing silver is melted in large pots. Zinc dust to the extent of only 1% is added and thoroughly stirred. The temperature is raised above the melting point of zinc. Zinc dissolves silver and comes up on the surface where zinc-silver alloy forms a crust. This is skimmed off by perforated ladles. More zinc is added and the operation is repeated for several times till lead shows almost no trace of dissolved silver. It is possible to reduce the silver content to 0.0005%.

The zinc-silver alloy containing some lead is now distilled with a little charcoal when zinc distills over. The recovered zinc is used again. The lead silver alloy left behind is now put to cupellation as to remove lead. The pure silver is, thus, obtained.

# 4. Recovery of silver from anodic mud of copper refining

The mud is treated with nitric acid and the solution is filtered. The filtrate contains nitrates of silver and lead. To the filtrate HCl is then added when silver and lead settle down as chlorides in the form of white precipitate. The chlorides are separated, dried and fused with sodium carbonate in a crucible when an alloy of Ag and Pb is obtained. To remove lead, the alloy is put to cupellation.

Anodic mud + HNO<sub>3</sub> 
$$\longrightarrow$$
 Nitrates of Ag and Pb (Filtrate)
$$\downarrow + \text{HCl}$$

$$Ag \xrightarrow{\text{Cupellation}} Ag \xrightarrow{\text{Pb}} \text{Pb} \xleftarrow{\text{Fused}} Ag\text{Cl} \cdot \text{PbCl}_2$$

$$Pb(NO_3)_2 + 2\text{HCl} \longrightarrow Pb\text{Cl}_2 + 2\text{HNO}_3$$

$$AgNO_3 + \text{HCl} \longrightarrow Ag\text{Cl} + \text{HNO}_3$$

$$Pb\text{Cl}_2 + \text{Na}_2\text{CO}_3 \longrightarrow Pb + 2\text{NaCl} + \text{CO}_2 + \frac{1}{2}\text{O}_2$$

$$2\text{AgCl} + \text{Na}_2\text{CO}_3 \longrightarrow 2\text{Ag} + 2\text{NaCl} + \text{CO}_2 + \frac{1}{2}\text{O}_2$$

#### 5. Silver from coins or ornaments

Coins and ornaments are alloys of silver and copper. The alloy is treated with nitric acid. Both copper and silver go into

the solution in the form of nitrates. The excess of nitric acid is boiled and the solution is treated with dil. HCl when a white precipitate of silver chloride is obtained. This is separated and converted into silver by any of the following methods.

(a) Silver chloride is fused with sodium carbonate in a crucible.

$$2AgCl + Na_2CO_3 \xrightarrow{Fuse} 2Ag + 2NaCl + CO_2 + \frac{1}{2}O_2$$

(b) The precipitate of AgCl is reduced with nascent hydrogen produced by the action of zinc and dilute H<sub>2</sub>SO<sub>4</sub>.

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + 2H$$
  
 $AgCl + H \longrightarrow Ag + HCl$ 

(c) AgCl is dissolved in potassium cyanide solution when a complex salt, potassium argento-cyanide is formed.

$$AgCl + 2KCN \longrightarrow KAg (CN)_2 + KCl$$

Ag is obtained from the solution by addition of zinc.

$$2KAg(CN)_2 + Zn \longrightarrow K_2Zn(CN)_4 + 2Ag$$
 Soluble

(d) By boiling silver chloride with caustic soda and glucose.

$$\begin{array}{c} 2AgCl + 2NaOH \longrightarrow Ag_2O + 2NaCl + H_2O \\ \\ Ag_2O + C_6H_{12}O_6 \longrightarrow 2Ag + C_6H_{12}O_7 \\ \\ \\ Glucose \\ \end{array}$$

The silver thus obtained, is purified by fusion with borax and nitre followed by electrolytic purification.

**Separation of silver from gold:** The separation of silver and gold is technically known as parting. This is done by following methods:

(a) Parting with sulphuric acid: The alloy having gold, less than 20%, is treated with boiling concentrated sulphuric acid. Silver dissolves as silver sulphate and gold remains as spongy mass. The solution is diluted with water and the solution is filtered. The filtrate is then treated with scrap iron or copper or zinc to separate silver.

$$Ag_2SO_4 + Zn \longrightarrow 2Ag + ZnSO_4$$

If the percentage of gold in the alloy is more than 20%, some silver is added to alloy as to reduce the percentage of gold less than 20% and then the process of parting is applied.

(b) Parting with 'Moebius' electrolytic process: The alloy of silver and gold is made the anode while pure silver plate as cathode. The electrolytic solution consists of a dilute solution of silver nitrate acidified with nitric acid. On passing electric current silver dissolves from the anode and deposits on the cathode. Gold remains undissolved and deposits as a slime in canvas bags surrounding the anode.

$$AgNO_{3}$$

$$\downarrow \downarrow$$

$$Ag^{+} + e \longrightarrow Ag \text{ cathode} \longleftarrow Ag^{+} + NO_{3}^{-} \longrightarrow Ag \text{ anode}$$

$$NO_{3}^{-} + Ag \longrightarrow AgNO_{3} + e$$

#### Properties

**Physical:** (a) It is a lustrous white metal. It melts at 961°C and boils at 2180°C. Its specific gravity is 10.5. (b) It is very good conductor of heat and electricity (better than even copper). (c) On heating, the molten mass absorbs oxygen which is again released on cooling. This property is called **spitting of silver.** (d) It is hard, malleable and ductile.

Chemical: (a) Action of atmosphere: Silver remains untarnished in air free from hydrogen sulphide. Air contaminated with hydrogen sulphide covers it with an adherent film of black silver sulphide.

$$2Ag + H_2S \longrightarrow Ag_2S + H_2$$

- **(b) Action of oxygen and water:** Silver is not affected by oxygen and water.
- (c) Action of halogens: Silver combines slowly with free halogens even at room temperature. The reaction is rapid at red heat.

$$2Ag + X_2 \longrightarrow 2AgX \quad (X_2 = Cl_2, Br_2 \text{ or } I_2)$$

(d) Action of acids: Silver is not affected by dilute and concentrated hydrochloric acid. It is also not acted upon by dilute sulphuric acid.

In concentrated sulphuric acid, silver dissolves on heating with evolution of sulphur dioxide.

$$\frac{\text{H}_2\text{SO}_4 \longrightarrow \text{H}_2\text{O} + \text{SO}_2 + \text{O}}{2\text{Ag} + \text{H}_2\text{SO}_4 + \text{O} \longrightarrow \text{Ag}_2\text{SO}_4 + \text{H}_2\text{O}}$$

$$\frac{2\text{Ag} + 2\text{H}_2\text{SO}_4 \longrightarrow \text{Ag}_2\text{SO}_4 + \text{SO}_2 + 2\text{H}_2\text{O}}{2\text{Ag} + 2\text{H}_2\text{SO}_4 \longrightarrow \text{Ag}_2\text{SO}_4 + \text{SO}_2 + 2\text{H}_2\text{O}}$$

Silver dissolves in both dilute and concentrated nitric acids.

Dilute HNO<sub>3</sub>: 
$$2HNO_3 \longrightarrow H_2O + 2NO + 3[O]$$

$$[2Ag + 2HNO_3 + O \longrightarrow 2AgNO_3 + H_2O] \times 3$$

$$6Ag + 8HNO_3 \longrightarrow 6AgNO_3 + 2NO + 4H_2O$$
or  $3Ag + 4HNO_3 \longrightarrow 3AgNO_3 + NO + 2H_2O$ 
Conc. HNO<sub>3</sub>:  $2HNO_3 \longrightarrow H_2O + 2NO_2 + O$ 

$$2Ag + 2HNO_3 + O \longrightarrow 2AgNO_3 + H_2O$$
or  $Ag + 2HNO_3 \longrightarrow AgNO_3 + NO_2 + 2H_2O$ 

- (e) Action of alkalies: Alkalies have no action on silver even when fused.
- (f) Action of alkali cyanides: Silver dissolves in the solution of alkali cyanides in the presence of oxygen forming the complex argentocyanide.

$$4Ag + 8KCN + 2H2O + O2 \longrightarrow 4K[Ag(CN)2] + 4KOH$$

$$4Ag + 8NaCN + 2H2O + O2 \longrightarrow 4Na[Ag(CN)2] + 4NaOH$$

#### **■** Uses

(i) Silver is used in making coins, ornaments, silver-ware, decoration pieces, etc. Pure silver is too soft to be used for these purposes and is, therefore, alloyed generally with copper.

Silver ornaments and utensils usually contain 80% silver and 20% copper. A silver coin has generally the composition Ag 50%, Cu 40%, Zn 5% and Ni 5%.

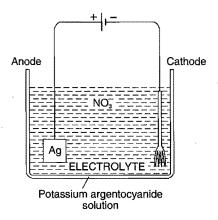

Fig. 14.14

(ii) Silver is used for plating articles of base-metals. The article to be plated is made the cathode while the anode consists of pure silver. The electrolyte is the solution of potassium argentocyanide. As the complex ion is very stable, the concentration of silver ion in solution is very small at any time.

$$[Ag(CN)_2]^- \iff Ag^+ + 2CN^-$$

Silver is deposited slowly and uniformly when electricity is passed through the solution.

- (iii) Silver amalgam is used in filling teeth and in silvering mirrors.
- (iv) Silver leaves are used in Ayurvedic and Yunani medicines.
- (v) It is used for making silver salts used in silvering of mirrors, photography and medicine.

# 14.18 COMPOUNDS OF SILVER

# Silver nitrate (Lunar caustic), AgNO<sub>3</sub>

Silver nitrate is the most common and important salt of silver.

#### Preparation

It is prepared by heating silver with dilute nitric acid. The solution is concentrated and cooled when the crystals of silver nitrate separate out.

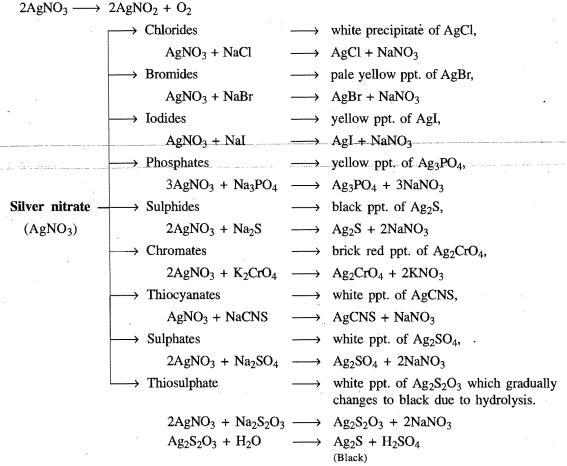

$$3Ag + 4HNO_3 \xrightarrow{Heat} 3AgNO_3 + NO + 2H_2O$$

#### Properties

- (a) It is a colourless crystalline compound, soluble in water and alcohol. It melts at 212°C.
- (b) In contact with organic substances it blackens due to decomposition into metallic silver. Thus, it leaves black stains

when comes in contact with skin and clothes. It produces burning sensation like caustic and leaves a white stain (usually a black stain) like the moon luna on skin and thus, called Lunar caustic. It is decomposed by light also and therefore stored in coloured bottles.

(c) On heating above its melting point, it decomposes to silver nitrite and oxygen.

On account of these reactions, silver nitrate is an excellent laboratory reagent for the identification of various acidic radicals.

- (e) Solid AgNO<sub>3</sub> absorbs ammonia gas with the formation of an addition compound, AgNO<sub>3</sub>·2NH<sub>3</sub>.
- (f) When treated with a solution of NaOH, it forms precipitate of silver oxide. Originally, it has brown colour but turns black when dried.

$$2AgNO_3 + 2NaOH \longrightarrow Ag_2O + 2NaNO_3 + H_2O$$

(g) When KCN is added to silver nitrate, a white precipitate of silver evanide appears which dissolves in excess of KCN forming a complex salt, potassium argento cyanide.

$$\begin{array}{ccc} \text{AgNO}_3 + \text{KCN} & \longrightarrow & \text{AgCN} + \text{KNO}_3 \\ \text{AgCN} + \text{KCN} & \longrightarrow & \text{KAg(CN)}_2 \\ & & \text{Potassium argentocyanide} \end{array}$$

(h) When sodium thiosulphate is added to silver nitrate, a white precipitate of silver thiosulphate appears. This precipitate, however, dissolves in excess of sodium thiosulphate forming a complex salt.

When heated at red heat, it further decomposes to metallic silver.

$$2AgNO_3 \longrightarrow 2Ag + 2NO_2 + O_2$$

(d) Solutions of halides, phosphates, sulphides, chromates, thiocyanates, sulphates and thiosulphates, all give a precipitate of the corresponding silver salt with silver nitrate solution.

 $AgNO_3 + NaI \longrightarrow AgI + NaNO_3$  $\rightarrow$  yellow ppt. of Ag<sub>3</sub>PO<sub>4</sub>,

- (i) AgNO<sub>3</sub> reacts with iodine in two ways:
- (a)  $6AgNO_3$  (excess) +  $3I_2$  +  $3H_2O \longrightarrow$  $AgIO_3 + 5AgI + 6HNO_3$

(b) 
$$5AgNO_3 + 3I_2$$
 (excess)  $+ 3H_2O \longrightarrow HIO_3 + 5AgI + 5HNO_3$ 

(j) Silver is readily displaced from an aqueous silver nitrate solution by the base metals, particularly, if the solution is somewhat acidic,

$$2AgNO_3 + Cu \longrightarrow 2Ag + Cu(NO_3)_2$$
  
 $2AgNO_3 + Zn \longrightarrow 2Ag + Zn(NO_3)_2$ 

(k) Phosphine, arsine and stibine all precipitate silver from silver nitrate solution.

$$PH_3 + 6AgNO_3 + 3H_2O \longrightarrow 6Ag + 6HNO_3 + H_3PO_3$$

$$AsH_3 + 6AgNO_3 + 3H_2O \longrightarrow 6Ag + 6HNO_3 + H_3AsO_3$$

(l) All halogen acids, except HF, precipitate silver halides from aqueous solution of AgNO<sub>3</sub>.

$$AgNO_3 + HX \longrightarrow AgX + HNO_3$$

(m) When NH<sub>4</sub>OH is added to silver nitrate solution, a brown precipitate of silver oxide appears which dissolves in excess of ammonia forming a complex salt.

$$2 AgNO_3 + 2NH_4OH \longrightarrow Ag_2O + 2NH_4NO_3 + H_2O$$
 
$$Ag_2O + 2NH_4NO_3 + 2NH_4OH \longrightarrow 2[Ag(NH_3)_2]NO_3 + 3H_2O$$

The ammonical solution of AgNO<sub>3</sub> gives the following reactions:

(a) It reacts with acetylene to form white compound, silver acetylide.

$$2AgNO_3 + 2NH_4OH + C_2H_2 \longrightarrow Ag_2C_2 + 2NH_4NO_3 + 2H_2O$$
  
Silver acetylide

(b) It converts glucose to gluconic acid.

$$Ag_2O + C_6H_{12}O_6 \longrightarrow 2Ag + C_6H_{12}O_7$$

(c) It oxidises formaldehyde to formic acid.

$$Ag_2O + HCHO \longrightarrow 2Ag + HCOOH$$

## Uses

- (i) It is used as a laboratory reagent for the identification of various acidic radicals especially for chloride, bromide and iodide. The ammonical silver nitrate solution, *i.e.*, Tollen's reagent is used in organic chemistry for testing aldehydes, reducing sugars, etc.
- (ii) Silver nitrate used for making silver halides which are used in photography.
- (iii) It is used in the preparation of making inks and hair dyes.
- (iv) A very dilute solution is used in causterisation of eyes. The salt is sometimes used as a dental antiseptic.
- (v) It is used extensively for the preparation of silver mirrors. The process of depositing a thin and uniform layer of silver on a clean glass surface is known as **silvering of mirrors**. It is employed for making looking glasses, concave mirrors and reflecting surfaces. The process is based on the reduction of ammonical silver nitrate solution by some reducing agent like formaldehyde, glucose, etc. The silver film deposited on the glass is first coated with a varnish and finally painted with red lead to prevent its being scraped off.

## Silver bromide, AgBr

## Preparation

It is prepared by the reaction of silver nitrate with a soluble bromide.

$$AgNO_3 + NaBr \longrightarrow AgBr + NaNO_3$$

### Properties

(a) It is a pale yellow solid. It is insoluble in water and concentrated acids. It is partially soluble in strong solution of ammonium hydroxide due to complex formation.

$$AgBr + 2NH_4OH \longrightarrow Ag(NH_3)_2Br + 2H_2O$$

- (b) On heating, it melts to a red liquid.
- (c) It is most sensitive to light. It undergoes photoreduction.

$$2AgBr \xrightarrow{Light} 2Ag + Br_2$$

(d) It dissolves in potassium cyanide.

AgBr + 2KCN 
$$\longrightarrow$$
 KAg(CN)<sub>2</sub> + KBr

Potassium argento-
cyanide (Soluble)

(e) It dissolves in sodium thiosulphate.

$$\begin{array}{c} AgBr + 2Na_2S_2O_3 \longrightarrow & Na_3[Ag(S_2O_3)_2] + NaBr \\ & Sodium \ argento- \\ & thiosulphate \ (Soluble) \end{array}$$

(f) AgBr is reduced to silver, when treated with zinc and dilute H<sub>2</sub>SO<sub>4</sub>.

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + 2H$$
  
 $2AgBr + 2H \longrightarrow 2Ag + 2HBr$ 

[Note: All above reactions are also observed in the case of AgCl. However, it is white and fairly soluble in ammonium hydroxide. It is sensitive to light.]

#### Uses

It is used for making photographic films and plates because it is sensitive to light.

## 14.19 GOLD

Occurrence: Gold is mainly found in native state either mixed with quartz in ancient rocks (vein gold) or scattered in sand and gravel (placer gold) or in the alluvial sand (alluvial gold) of certain rivers which pass over auriferous rocks. It is also found to a small extent in combined state as sulphide, telluride or arsenosulphide. The important sources of gold are:

- (i) Alluvial sand or gravel
- (ii) Calaverite AuTe<sub>2</sub>
- (iii) Sylvanite AuAgTe<sub>2</sub>

Mainly gold comes from the mines of South Africa. India produces about 2% of the total world production. **Kolar Mines** in Karnataka produce about 99% of our gold output.

**Extraction:** (i) From alluvial sa From alluvial sands, gold is recovered by making use of its high specific gravity (19.3). The oldest method is **pan washing.** In big pans made of iron or zinc, the gold bearing sand is agitated by giving a rotatory motion to the pan when the heavier gold particles settle down whereas the sand is washed away. This has now been replaced by placer mining.

Gold bearing sand is introduced in a sluice way system and powerful streams of water are passed over it. A **sluice way system** is an inclined channel made up of wood having a series of sluices, *i.e.*, troughs and cross wire strips known as riffles. The gold particles are retained in the sluice whereas sand particles are taken away by the water.

(ii) From auriferous quartz: The bigger pieces of auriferous quartz are crushed and broken into small pieces by rock crushers and then powdered by a battery of stamp mills working in series. The powdered ore is washed out of stamp mill by a current of water, when only fine particles can pass through the screen.

## Amalgamation process

The slurry from the stamp mill is passed over amalgamated copper plates placed just infront of stamp mills. The gold combines with mercury to form amalgam which is removed from the plates.

The amalgam is then distilled when the mercury passes over leaving behind gold. This process can remove 70-80% of the gold. The residual part is known as **tailings**.

The tailings or the concentrated ore of gold is put in large vats made of wood or cement having perforated false bottoms covered with coconut mattings. This is treated with 0.1% solution of NaCN in the presence of excess of air. The gold dissolves according to the following reaction.

$$4Au + 8NaCN + 2H_2O + O_2 \longrightarrow 4Na[Au(CN)_2] + 4NaOH$$

The gold solution obtained is treated with zinc dust when gold being less electropositive gets precipitated.

$$2Na[Au(CN)_2]+Zn \longrightarrow Na_2Zn(CN)_4 + 2Au$$

The precipitated gold is recovered by filtration.

The crude gold contains silver, copper, zinc, lead, etc., as impurities. These impurities are removed by cupellation and parting process. Gold can be refined by electrolytic process also.

#### Fineness of Gold

Gold is a precious and noble metal. It is very stable towards common reagents and resists the action of the atmosphere. It is not attacked by air or oxygen or water at any temperature. Since it retains its bright surface untarnished, it is used for making ornaments, jewellery and watches. Generally, small quantities of other metals, especially copper, are added to the gold to make it harder. The purity or fineness of gold is generally expressed in **carats**, pure gold being known as 24 carats. Ornaments available these days are made of 18 carats. This is an alloy of gold containing 18 parts gold and 6 parts other metals.

Thus, percentage of gold in 18 carats is  $\frac{100}{24} \times 18$ , *i.e.*, 75 and the percentage of other metals is 25.

# 14.20 POSITION OF ZINC FAMILY IN PERIODIC TABLE

Group 12 (IIB) of the long form of periodic table consists of four elements namely zinc (Zn), cadmium (Cd), mercury (Hg), and ununbium(Uub)\*. These are collectively called as zinc metals as zinc is the predominant member. These elements are the end members of the four series of d-block elements as the last differentiating electron is accommodated on (n-1)d energy shell. Zinc is the last member of 3d series, cadmium is the last member of 4d series, mercury is the last member of 5d-series and ununbium is the last member of 6d series.

Group	IB (11)	11B	111A
Period		(12)	(13)
4	Cu	Zn	Ga
	(29)	(30)	(31)
5	Ag	Cd	In
	(47)	(48)	(49)
6	Au	Hg	Tl
	(79)	(80)	(81)
7	Uuu	Uub	Uut
	(111)	(112)	(113)

3d series Sc (Ist member,  $3d^1$ ) . . .Zn (last member,  $3d^{10}$ ) 4d series Y (Ist member,  $4d^1$ ) . . .Cd (last member,  $4d^{10}$ ) 5d series La (Ist member,  $5d^1$ ) . . .Hg (last member,  $5d^{10}$ ) 6d series Ac (Ist member,  $6d^1$ ) . . .Uub (last member,  $6d^{10}$ )

IIB group is present between IB (Transition elements) and IIIA (Normal elements). Thus, the elements of IIB show mixed properties of transition elements and normal elements. The inclusion of Zn, Cd, Hg and Uub in the same sub-group of the periodic table is justified by the similarities and gradation in their properties as the atomic number increases from Zn to Uub.

# 1. Electronic configuration

They have similar electronic configuration. The distribution of the electrons in various energy shells of these atoms is shown below:

Zn	30	2, 8, 18, 2	$3d^{10}$ , $4s^2$
Cd	48	2, 8, 18, 18, 2	4 $d^{10}$ , $5s^2$
Hg	80	2, 8, 18, 32, 18, 2	5 $d^{10}$ , $6s^2$
Uub	112	2, 8, 18, 32, 32, 18, 2	6 $d^{10}$ , $7s^2$

<sup>\*</sup>Ununbium is recently discovered synthetic radioactive element. Not much is known about its properties.

These configurations show that outermost shell has two electrons while the penultimate shell contains 18 electrons, *i.e.*, they have general configuration  $(n-1)d^{10}ns^2$ . Thus, these are d-block elements but do not show many properties which are shown by d-block elements. For example, (i) They do not show variable valency. (ii) Most of their compounds are colourless. (iii) Their melting and boiling points are very low. (iv) These are diamagnetic. (v) These are more electropositive as the oxidation potentials for zinc and cadmium being positive. This is due to the completion of (n-1)d energy shell which has 10 electrons (the maximum capacity of d-subshell).

### 2. Valency

All the elements show divalency as only  $ns^2$  electrons are lost by these elements.  $M^{2+}$  ions produced, possess  $(n-1)d^{10}$  configuration. This configuration is stable and hence cannot lose any more electrons. However, mercury forms two series of salts, viz., mercurous salts containing  $Hg_2^{2+}$  ion and mercuric salts containing  $Hg_2^{2+}$  ion. Both these ions show divalency of mercury. Mercurous ion does not exist as  $Hg^+$  but as  $Hg_2^{2+}$ . Thus, mercurous chloride exists as Cl-Hg-Hg-Cl and not as Hg-Cl.

#### 3. Occurrence

They do not occur in free state. All these metals occur as sulphides which constitute their important ores. Cadmium is usually found in the ores of zinc. However, mercury occurs in small quantities in the native state.

## 4. Physical characteristics

- (a) **Physical state:** Zinc and cadmium are solids while mercury is a liquid at ordinary temperature. The interatomic forces of attraction are considerably weak. These are so small in mercury that it exists in liquid state.
- (b) Melting and boiling points: The melting and boiling points are low as electrons from (n-1)d-shell are not available for bonding.

Element	Zn	Cd	Hg
M. pt. (°C)	419.5	320.9	-38.4
B. pt. (°C)	907	765	357

These metals are volatile in nature and easily come into vapour state.

atomic radii are fairly large, *i.e.*, more than coinage metals but less than alkaline earth metals. Atomic radii, atomic volume and density gradually increases from Zn to Hg.

Element	Zn	Cd	Hg
Atomic radii	1.25	1.41	1.44
Atomic volume	9.20	13.10	14.80
Density	7.10	8.60	13.60

(d) Ionisation energy and oxidation potential: These metals have fairly high values of ionisation energies. The values indicate that these metals should be less reactive. In fact, they are even more reactive than the coinage metals. This is due to their high values of oxidation potentials which are positive for Zn and Cd. The ionisation potential does not follow the regular trend. The electropositive nature and the chemical activity decreases from Zn to Hg. Hg is somewhat noble in nature.

Element	Zn	Cd	Hg
First ionisation potential (eV)	9.40	9.00	10.40
Oxidation potential (volt)	0.76	0.40	-0.85

(e) Other physical properties: All the three metals are good conductors of electricity. These are greyish white lustrous metals. These are malleable and ductile. The malleability and ductility decreases from Zn to Cd. Except Hg, other two metals are moderately hard.

# 5. Chemical nature of the metals and their compounds

(a) Action of air and water: The effect of atmosphere decreases from Zn to Hg. Zinc is slowly coated with a bluish white protective film of oxide in moist air, cadmium is much less affected while mercury is not affected at all.

Zinc decomposes boiling water slightly but at red heat, zinc decomposes steam easily. Cadmium resembles zinc but is much less reactive. Mercury is not affected under any conditions.

$$Zn + H_2O \longrightarrow ZnO + H_2$$

**(b) Action of oxygen:** All form oxides of the type *MO* when heated in air or oxygen. Basic properties increases. ZnO is amphoteric while CdO and HgO are basic in character. These are insoluble in water.

$$ZnO + 2HCl \longrightarrow ZnCl_2 + H_2O$$
 $ZnO + 2NaOH \longrightarrow Na_2ZnO_2 + H_2O$ 
Sodium zincate
 $HgO + H_2SO_4 \longrightarrow HgSO_4 + H_2O$ 

The stability of the oxides towards the action of heat decreases in the order of Zn, Cd, Hg. Zinc oxide and cadmium oxide sublime.HgO does not sublime because it decomposes on heating.

$$2HgO \longrightarrow 2Hg + O_2$$

The colours of these oxides are interesting. Zinc oxide is white at room temperature but turns yellow on heating. At high temperature metal excess non-stoichiometry is shown by ZnO. Cadmium oxide has chocolate brown colour but is white at liquid air temperature. Mercury oxide is known in two forms: yellow and red. The colour difference is due to particle size.

Both Zn and Cd form peroxides,  $ZnO_2$  and  $CdO_2$ , when their hydroxides are treated with  $H_2O_2$  solution. These peroxides are less stable. Hg does not form peroxide.

(c) Action of acids: Both zinc and cadmium dissolve in dilute hydrochloric acid and sulphuric acid with evolution of hydrogen but mercury remains unattacked.

$$Zn + 2HCl \longrightarrow ZnCl_2 + H_2$$
  
 $Cd + 2HCl \longrightarrow CdCl_2 + H_2$   
 $Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$   
 $Cd + H_2SO_4 \longrightarrow CdSO_4 + H_2$ 

Zinc and cadmium dissolve in dilute and concentrated nitric acid forming N<sub>2</sub>O, NO, NO<sub>2</sub> or NH<sub>3</sub> depending on the concentration of the acid. However, Hg with dilute HNO<sub>3</sub> forms mercurous nitrate and nitric oxide and with concentrated nitric acid it forms mercuric nitrate and nitrogen dioxide.

$$6$$
Hg +  $8$ HNO $_3$  (dil.)  $\longrightarrow 3$ Hg $_2$ (NO $_3$ ) $_2$  +  $2$ NO +  $4$ H $_2$ O  
Hg +  $4$ HNO $_3$  (conc.)  $\longrightarrow$ Hg(NO $_3$ ) $_2$  +  $2$ NO $_2$  +  $2$ H $_2$ O

Hot concentrated sulphuric acid dissolves all the metals with the evolution of sulphur dioxide.

$$M + 2H_2SO_4 \longrightarrow MSO_4 + SO_2 + 2H_2O$$
  
(Hot and conc.)

(d) Action of alkalies: Zinc dissolves in caustic alkalies with formation of zincates and evolution of hydrogen. Cadmium and mercury are not affected.

$$Zn + 2NaOH \longrightarrow Na_2ZnO_2 + H_2$$

(e) Halides: These metals directly react with halogens.  $M + X_2 \longrightarrow MX_2$ 

The nature of the bond depends on the polarising power of the cation and the polarisability of the anion. It is observed that polarising power increases from Zn to Hg and from F to I. The covalent nature of halides increases from Zn to Hg and from F to I. All the halides except  $HgI_2$  are white solids, they have low melting points and are easily volatile.  $HgI_2$  is red but it becomes yellow on heating at  $126^{\circ}$ C. All the halides, except fluorides, form halo complexes of the type  $MX_3^-$  and  $MX_4^{2-}$  with halide ions.

(f) Sulphides: All form sulphides of the type MS, which can be precipitated by passing  $H_2S$  through their salts solutions.

The solubility products of the sulphides decrease from Zn to Hg. ZnS is soluble in dilute acids, CdS is soluble in concentrated acids but HgS is insoluble even in concentrated acids. HgS is soluble in aqua-regia.

**(g) Oxysalts:** The sulphates, nitrates, acetates and perchlorates of these metals are soluble in water. The carbonates and oxalates are insoluble. Various salts are thermally less stable. The ease of decomposition increases from zinc to mercury. Mercury salts yield mercury in some cases.

$$ZnCO_3 \longrightarrow ZnO + CO_2$$
  
 $2ZnSO_4 \longrightarrow 2ZnO + 2SO_2 + O_2$ 

$$2Zn(NO_3)_2 \longrightarrow 2ZnO + 4NO_2 + O_2$$

$$Hg_2CO_3 \longrightarrow HgO + Hg + CO_2$$

$$3HgSO_4 \longrightarrow Hg_2SO_4 + Hg + 2SO_2 + 2O_2$$

$$2Hg(NO_3)_2 \longrightarrow 2HgO + 4NO_2 + O_2$$

All the three elements form double sulphates crystallising with six molecules of water, for example, K<sub>2</sub>SO<sub>4</sub>·2nSO<sub>4</sub>·6H<sub>2</sub>O.

**(h) Complexes:** All the three elements form complexes particularly with cyanide ions, ammonia, halide ions and many other ligands. The complexes of  $Hg^{2+}$  are much more stable than  $Zn^{2+}$  and  $Cd^{2+}$ . The most common coordination number of Zn and Cd in the complexes is four. Quite a few six coordinated complexes are also known. Some examples are given below:

$$[Zn(NH_3)_4]SO_4 \qquad [Cd(NH_3)_4]SO_4$$

$$K_2Zn(CN)_4 \qquad K_2Cd(CN)_4$$

$$[Zn(en)_3]^{2+} \qquad [Cd(en)_3]^{2+}$$

$$(en = ethylene diamine)$$

The common coordination numbers of mercury are 2 and 4. For example, Hg(NH<sub>2</sub>)Cl and K<sub>2</sub>HgI<sub>4</sub>.

(i) Alloys and amalgams: Zinc forms a number of alloys with other metals. Cadmium is used for making low melting alloys with lead, bismuth and tin. Mercury forms a series of combinations with other metals known as amalgams.

# 14.21 ZINC

**Occurrence:** Zinc is usually found in the combined state although traces of the metal in the native state have been reported from Melbourne (Australia). Its chief ores are:

- 1. Zinc blende, ZnS. It is found in Burma, Belgium, Silesia and Oklahoma.
  - 2. Calamine or zincspar, ZnCO<sub>3</sub>
  - 3. Zincite, ZnO
  - 4. Willemite, Zn<sub>2</sub>SiO<sub>4</sub>

Traces of zinc in the form of organo-metallic compounds have been reported in the animal cells and in snake-poison. In India, zinc is mainly found at Zawar in Rajasthan.

**Extraction:** Zinc is extracted from its ores by two methods:

- 1. Reduction process
- 2. Electrolytic process.

#### 1. Reduction Process

It involves the following steps:

- (i) Concentration: When zinc blende is used, the powdered ore is concentrated by froth floatation process. In the case of calamine ore, the concentration is done by gravity process. If the ore contains iron oxide, the latter is removed by magnetic separation.
- (ii) Roasting: The concentrated ore is heated in excess of oxygen at about 900°C. Zinc sulphide is oxidised to zinc oxide. If some of the ore is oxidised to zinc sulphate, it also decomposes at 900°C into ZnO.

$$2ZnS + 3O_2 \longrightarrow 2ZnO + 2SO_2$$
  
 $ZnS + 2O_2 \longrightarrow ZnSO_4$   
 $2ZnSO_4 \longrightarrow 2ZnO + 2SO_2 + O_2$ 

When the ore is calamine, it shall decompose into oxide with evolution of carbon dioxide.

$$ZnCO_3 \longrightarrow ZnO + CO_2$$

For roasting, a reverberatory furnace may be used.

(iii) Reduction: The principal reaction that takes place during reduction is the conversion of the oxide into the metal with the help of carbon.

$$ZnO + C \longrightarrow Zn + CO$$

There are different types of reducing furnaces for the reduction of the oxide. All make use of the same principle but differ only in the details of construction and method by which the metal is separated.

(a) Belgian process: It is an old process. The roasted ore is heated with coke to about 1100°C in a small fireclay retorts. The heating is often done by producer gas. Each retort

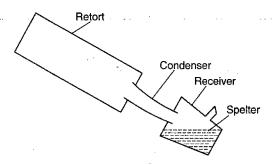

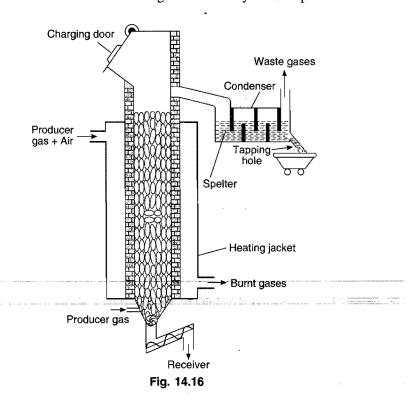

Fig. 14.15

is filled with a mixture of 2 parts ore and one part coke. The retorts are about 1.5 metre long and 25 cm in diameter. Each retort is circular or elliptical in shape and closed at one end. The mouth of each retort is provided with an earthenware condenser. The temperature is raised to about 1100°C, the CO formed during the process burns at the mouth of the retorts and when the colour of the flame changes from blue to greenish white, the condensers are fitted there on. These condensers are cooled by air and the metal condenses in these partly as a fused metal (spelter) and partly as a powder (zinc dust).

There are number of such retorts which are arranged in three or four rows one above the other.

**(b) Vertical retorts process :** This is a continuous process and is largely used these days. It is economical also.

In this process the vertical retorts of about 7.5 metre height are used. Each is connected with an arrangement for continuous

feeding of roasted ore and powdered coke. Retorts are made of highly refractory silicon carbide bricks capable of withstanding high temperature 1300°C. The retorts are heated externally by producer gas. There is an extension at the bottom through which ash can be removed. The open end of the retort is connected with condensers. Zinc vapour and carbon monoxide pass into the condensers when zinc liquefies. Molten zinc is periodically taped off from the condensers and carbon monoxide is used as fuel for heating the furnace.

(iv) Purification: The zinc obtained above is impure containing 97.8% zinc and rest impurities of lead, iron, cadmium, arsenic, etc. This impure zinc is known as spelter. This is put to further purification by distillation. The distillation is carried around 950–1000°C when only zinc (b. pt. 907°C) and cadmium (b. pt. 767°C) distil over. From this sample, cadmium is removed at 800°C.

The impure zinc can also be purified electrolytically. The impure metal is made anode and cathode consists of sheets of pure aluminium. A solution of zinc sulphate acts as an electrolyte. Zinc dissolves from anode and deposits on cathode when electric current is passed. Zinc is scraped off from the aluminium sheets.

## 2. Electrolytic Process

This method is gradually replacing the reduction process. The roasted ore is dissolved in dilute sulphuric acid and the solution is filtered. The solution is freed from iron, aluminium, silica, etc., by treatment with calcium hydroxide. Copper and cadmium are removed by precipitation with zinc dust at 75°C.

$$FeSO_4 + Ca(OH)_2 \longrightarrow Fe(OH)_2 + CaSO_4$$

$$CdSO_4 + Zn \longrightarrow Cd + ZnSO_4$$

$$CuSO_4 + Zn \longrightarrow Cu + ZnSO_4$$

The filtered solution is subjected to electrolysis by using a sheet of pure aluminium as cathode and pure lead plate as anode. The zinc is removed from cathode by melting. The zinc obtained is 99.95% pure.

Granulated zinc is made by melting the metal in a crucible and pouring the drops in water. Zinc sheet is formed by heating the metal at 150°C when it becomes soft and then can be rolled into sheets.

### Properties

**Physical:** (a) It is a bluish white metal. It acquires grey colour when exposed to moist atmosphere. (b) It melts at 419.5°C and boils at 907°C. (c) It has specific gravity 7.1. (d) It is malleable and ductile. (e) It is good conductor of heat and electricity.

Chemical: (a) Action of air: It is not affected by dry air. In moist air, a protective thin film of basic carbonate is formed on its surface. When heated in air strongly, it burns forming a white smoke which settles down to soft wooly flocks of zinc oxide called the *philosopher's wool* or *pompholyx*.

$$2Zn + O_2 \longrightarrow 2ZnO$$

(b) Action of water: Pure zinc is not affected by water. The commercial zinc decomposes boiling water. At red heat, the metal decomposes steam evolving hydrogen.

$$Zn + H_2O \longrightarrow ZnO + H_2$$

(c) Action of acids: Pure zinc is attacked slowly by acids but commercial zinc reacts readily with all acids. It dissolves in HCl (dilute and conc.) and dilute H<sub>2</sub>SO<sub>4</sub> evolving hydrogen.

$$Zn + 2HCl \longrightarrow ZnCl_2 + H_2$$
  
 $Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$ 

It dissolves in concentrated H<sub>2</sub>SO<sub>4</sub> with evolution of SO<sub>2</sub>.

$$H_2SO_4 \longrightarrow H_2O + SO_2 + O$$

$$Zn + H_2SO_4 + O \longrightarrow ZnSO_4 + H_2O$$

$$Zn + 2H_2SO_4 \longrightarrow ZnSO_4 + SO_2 + 2H_2O$$

Dilute nitric acid gives nitrous oxide or ammonium nitrate depending on the strength of the acid.

$$[Zn + 2HNO_3 \longrightarrow Zn(NO_3)_2 + 2H] \times 4$$
  
 $2HNO_3 + 8H \longrightarrow NH_4NO_3 + 3H_2O$ 

$$4Zn + 10HNO_3 \longrightarrow 4Zn(NO_3)_2 + NH_4NO_3 + 3H_2O$$

Dilute HNO<sub>3</sub>: Nitrous oxide is evolved.

$$[Zn + 2HNO_3 \longrightarrow Zn(NO_3)_2 + 2H] \times 4$$

$$2HNO_3 + 8H \longrightarrow N_2O + 5H_2O$$

$$4Zn + 10HNO_3 \longrightarrow 4Zn(NO_3)_2 + N_2O + 5H_2O$$

Conc. HNO<sub>3</sub>: Nitrogen dioxide is evolved.

$$Zn + 2HNO_3 \longrightarrow Zn(NO_3)_2 + 2H$$
 $[HNO_3 + H \longrightarrow NO_2 + H_2O] \times 2$ 
 $Zn + 4HNO_3 \longrightarrow Zn(NO_3)_2 + 2NO_2 + 2H_2O$ 

(d) Action of alkalies: Zinc dissolves in hot caustic alkali solutions forming alkali zincate and evolving hydrogen.

$$Zn + 2KOH \longrightarrow K_2ZnO_2 + H_2$$
  
Pot. zincate

(e) Electropositive nature: Zinc displaces many metals such as lead, copper, silver, gold, etc., from their salt solutions as it is highly electropositive.

$$Zn + CuSO_4 \longrightarrow ZnSO_4 + Cu$$
  
 $Zn + 2AgNO_3 \longrightarrow Zn(NO_3)_2 + 2Ag$ 

(f) Action of ammonia: Zinc decomposes ammonia at red heat.

$$3Zn + 2NH_3 \longrightarrow Zn_3N_2 + 3H_2$$

(g) Action of halogens: It reacts with halogens directly.

$$\operatorname{Zn} + X_2 \longrightarrow \operatorname{Zn} X_2$$

(h) Action of sulphur: When heated with sulphur, it forms zinc sulphide.

$$Zn + S \longrightarrow ZnS$$

#### Uses

- (i) Zinc is used in the manufacture of various important alloys such as brass, german silver, etc.
- (ii) Zinc is used in Parkes process for the extraction of silver from argentiferous lead. Zinc dust is used for the extraction of Ag and Au by cyanide process.
  - (iii) Zinc dust is used in the laboratory as a reducing agent.
  - (iv) Zinc rods are used in making electric batteries.
- (v) The most important use of zinc is for the galvanising of iron. Galvanising is a process of depositing a thin layer of zinc over the surface of iron. The zinc coating protects the iron from corrosion. The iron articles to be galvanised are first cleaned by means of a sand blast and then dipped in dilute  $H_2SO_4$  and finally washed with water. The galvanisation is done either by spraying the molten zinc or dipping in molten zinc or electrolytically.

## 14.22 COMPOUNDS OF ZINC

**Zinc oxide, ZnO:** Zinc oxide is also called zinc white or chinese white or philosopher's wool. It occurs in nature as the mineral zincite or red zinc ore.

#### Preparation

It is obtained by the combustion of zinc or by the calcination of zinc carbonate, zinc nitrate or zinc hydroxide.

$$2Zn + O_2 \longrightarrow 2ZnO$$

$$ZnCO_3 \longrightarrow ZnO + CO_2$$
  
 $2Zn(NO_3)_2 \longrightarrow 2ZnO + 4NO_2 + O_2$   
 $Zn(OH)_2 \longrightarrow ZnO + H_2O$ 

Very pure zinc oxide is prepared by mixing a solution of zinc sulphate with sodium carbonate. The basic zinc carbonate thus, precipitated on heating gives pure zinc oxide.

$$4ZnSO_4 + 4Na_2CO_3 + 3H_2O \longrightarrow ZnCO_3 \cdot 3Zn(OH)_2$$

$$ppt.$$

$$+ 4Na_2SO_4 + 3CO_2$$

$$ZnCO_3 \cdot 3Zn(OH)_2 \xrightarrow{\text{Heat}} 4ZnO + 3H_2O + CO_2$$

## Properties

(i) It is a white powder. It becomes yellow on heating and again turns white on cooling. (ii) It is very light. It is insoluble in water. It sublimes at 400°C. (iii) It is an amphoteric oxide and dissolves readily in acids forming corresponding zinc salts and alkalies forming zincates.

$$ZnO + H_2SO_4 \longrightarrow ZnSO_4 + H_2O$$
  
 $ZnO + 2HCl \longrightarrow ZnCl_2 + H_2O$   
 $ZnO + 2NaOH \longrightarrow Na_2ZnO_2 + H_2O$   
Sodium zincate

(iv) When heated in hydrogen above 400°C, it is reduced to metal.

$$ZnO + H_2 \longrightarrow Zn + H_2O$$

It is also reduced by carbon into zinc.

$$ZnO + C \longrightarrow Zn + CO$$

(v) When zinc oxide is heated with cobalt nitrate, a green mass is formed due to formation of cobalt zincate which is known as **Rinmann's green.** 

$$2\text{Co}(\text{NO}_3)_2 \longrightarrow 2\text{CoO} + 2\text{NO}_2 + \text{O}_2$$
  
 $\text{ZnO} + \text{CoO} \longrightarrow \text{CoZnO}_2 \text{ or CoO·ZnO}$ 

## Uses

- (i) Zinc oxide is used as a white pigment (paint). No doubt its covering power is less than white lead but it is superior because it is not blackened in atmosphere of hydrogen sulphide. It can be used both as oil and water paint.
- (ii) It is used to prepare Rinmann's green which is employed as a green pigment.
- (iii) It finds use as a catalyst along with Cr<sub>2</sub>O<sub>3</sub> in the manufacture of methyl alcohol from water gas.
- (iv) It is used as a filler for soft rubber and as an absorbent in surgical dressing.
- (v) It is also used as zinc ointment in medicine and as a glaze in ceramics.
  - (vi) It is used for cosmetic powders and creams.

## Zinc Chloride, ZnCl<sub>2</sub>·2H<sub>2</sub>O

### Preparation

It is obtained by treating zinc oxide or zinc carbonate or zinc hydroxide with dilute hydrochloric acid. The solution on concentration and cooling gives hydrated zinc chloride crystals, ZnCl<sub>2</sub>·2H<sub>2</sub>O.

$$ZnO + 2HCl \longrightarrow ZnCl_2 + H_2O$$
  
 $ZnCO_3 + 2HCl \longrightarrow ZnCl_2 + CO_2 + H_2O$   
 $Zn(OH)_2 + 2HCl \longrightarrow ZnCl_2 + 2H_2O$ 

Anhydrous zinc chloride cannot be obtained by heating crystals of hydrated zinc chloride as hydrolysis occurs and basic chloride (zinc hydroxy chloride) is formed which on further heating gives zinc oxide.

$$ZnCl_2 \cdot 2H_2O \longrightarrow Zn(OH)Cl + HCl + H_2O$$
  
 $Zn(OH)Cl \longrightarrow ZnO + HCl$ 

The anhydrous zinc chloride is obtained by heating zinc in the atmosphere of dry chlorine or dry HCl gas.

$$Zn + Cl_2 \longrightarrow ZnCl_2$$
  
 $Zn + 2HCl \longrightarrow ZnCl_2 + H_2$ 

This can also be formed by distilling zinc pewder with mercuric chloride.

$$Zn + HgCl_2 \longrightarrow ZnCl_2 + Hg$$

## Properties

(a) Anhydrous zinc chloride is a white solid, deliquescent and soluble in water. It melts at 660°C and boils at 730°C. (b) Hydrated zinc chloride on heating forms zinc hydroxy chloride or zinc oxychloride.

$$ZnCl_2 \cdot 2H_2O \longrightarrow Zn(OH)Cl + HCl + H_2O$$
  
 $2ZnCl_2 \cdot 2H_2O \longrightarrow Zn_2OCl_2 + 2HCl + 3H_2O$   
Zinc oxychloride

(c) When H<sub>2</sub>S is passed through the solution, a white precipitate of zinc sulphide, is formed.

$$ZnCl_2 + H_2S \longrightarrow ZnS + 2HCl$$

(d) When NaOH is added, a white precipitate of zinc hydroxide appears which dissolves in excess of sodium hydroxide forming sodium zincate.

$$ZnCl_2 + 2NaOH \longrightarrow Zn(OH)_2 + 2NaCl$$
  
 $Zn(OH)_2 + 2NaOH \longrightarrow Na_2ZnO_2 + 2H_2O$ 

(e) On adding NH<sub>4</sub>OH solution, a white precipitate of zinc hydroxide appears which dissolves in excess of ammonia forming a complex salt.

$$ZnCl_2 + 2NH_4OH \longrightarrow Zn(OH)_2 + 2NH_4Cl \xrightarrow{3}$$
 $Zn(OH)_2 + 2NH_4OH + 2NH_4Cl \longrightarrow [Zn(NH_3)_4]Cl_2 + 4H_2O$ 
Tetrammine zinc chloride

Transition Elements or d-block Elements and f-block Elements

(f) When the solution of zinc chloride is treated with a solution of sodium carbonate, a white precipitate of basic zinc carbonate is formed.

But when a solution of sodium bicarbonate is used, a white precipitate of normal zinc carbonate is formed.

$$ZnCl_2 + 2NaHCO_3 \longrightarrow ZnCO_3 + 2NaCl + H_2O + CO_2$$

(g) Anhydrous zinc chloride absorbs ammonia gas and forms an addition compound.

$$ZnCl_2 + 4NH_3 \longrightarrow ZnCl_2 \cdot 4NH_3$$

- (h) Its syrupy solution dissolves cellulose.
- (i) Its syrupy solution when mixed with zinc oxide, ZnO, sets to a hard mass forming an oxychloride, ZnCl<sub>2</sub>·3ZnO.

#### **■** Uses

- (i) The concentrated solution of zinc chloride is used for impregnating timber to prevent its destruction from the action of micro-organisms.
- (ii) The mixture of syrupy zinc chloride solution and zinc oxide is used for dental filling.
  - (iii) It is used as dehydrating agent.
- (iv) Being acidic in aqueous solution, it is used for cleaning the surface of metals before soldering.
- (v) It is employed in making parchment paper; vulcanised fibre, cold water glues and adhesives. It is also used in the manufacture of dry cells.

# Zinc Sulphate (White vitriol), ZnSO4.7H2O

## Preparation

It is prepared by reacting zinc with dilute sulphuric acid. It can also be prepared by dissolving zinc oxide or carbonate in dilute sulphuric acid. The solution on concentration and crystallisation below 39°C gives colourless crystals of zinc sulphate,  $ZnSO_4 \cdot 7H_2O$ .

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$$
  
 $ZnO + H_2SO_4 \longrightarrow ZnSO_4 + H_2O$   
 $ZnCO_3 + H_2SO_4 \longrightarrow ZnSO_4 + H_2O + CO_2$ 

## Properties

- (a) It is a colourless, crystalline solid. It is an efflorescent substance. It is freely soluble in water.
  - (b) On heating, the following changes occur.

$$\begin{array}{c} ZnSO_4 \cdot 7H_2O \xrightarrow{Above \ 39^{\circ}C} ZnSO_4 \cdot 6H_2O \xrightarrow{Above \ 70^{\circ}C} ZnSO_4 \cdot H_2O \\ & Above \ 280^{\circ}C \bigcup \\ O_2 + SO_2 + ZnO \xrightarrow{(Anhydrous)} ZnSO_4 \end{array}$$

$$ZnSO_4 \xrightarrow{800^{\circ}C} ZnO + SO_3$$

$$\downarrow \qquad \qquad \downarrow \qquad \qquad \downarrow \qquad \qquad SO_2 + \frac{1}{2}O_2$$

(c) When sodium hydroxide is added to the solution of zinc sulphate, a white precipitate of zinc hydroxide appears which dissolves in excess of NaOH forming sodium zincate.

$$ZnSO_4 + 2NaOH \longrightarrow Zn(OH)_2 + Na_2SO_4$$
  
 $Zn(OH)_2 + 2NaOH \longrightarrow Na_2ZnO_2 + 2H_2O$ 

(d) When sodium carbonate solution is added to the solution of zinc sulphate, a white precipitate of basic zinc carbonate is formed.

$$4ZnSO_4 + 4Na_2CO_3 + 3H_2O \longrightarrow ZnCO_3 \cdot 3Zn(OH)_2 + 4Na_2SO_4 + 3CO_2$$

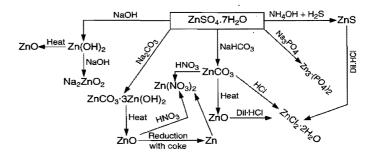

However, when the solution of sodium bicarbonate is added, normal zinc carbonate is formed.

$$ZnSO_4 + 2NaHCO_3 \longrightarrow ZnCO_3 + Na_2SO_4 + H_2O + CO_2$$

(e) With alkali metal sulphates and  $(NH_4)_2SO_4$ , it forms double sulphates such as  $K_2SO_4$ ·ZnSO<sub>4</sub>·6H<sub>2</sub>O.

#### Uses

- (i) A dilute solution of zinc sulphate is used as eye lotion.
- (ii) It is used for the preparation of lithopone (ZnS + BaSO<sub>4</sub>), a popular white paint.
  - (iii) It is employed as a mordant in dyeing and calicoprinting.
- (iv) The solution of zinc sulphate is used for zinc plating and in the electrolytic refining of zinc.
- (v) Zinc sulphate is used as a starting material for the preparation of other zinc compounds.

## 14.23 MERCURY

Occurrence: Mercury ores are rare. It occurs in small quantities in the native state. Cinnabar, HgS, is the most important ore and is found in Spain and Italy and small quantities in Russia, United States of America, Mexico, China and Japan.

**Extraction:** The extraction of mercury from cinnabar ore is comparatively simple and consists mainly the roasting and distillation. The extraction involves the following steps:

- (i) Crushing and concentration: The ore is crushed and finely powdered in ball mills and concentrated by froth floatation process.
- (ii) Combined roasting and distillation: There are two principal processes available which differ only in the type of furnace used.
- (a) Idrian furnace used in Almaden (Spain). This is the old process.
  - (b) Shaft furnace—This is the modern continuous process.

#### (a) Idrian Furnace

The concentrated ore is taken on the perforated arches and heated by the flame (Fig. 14.17).

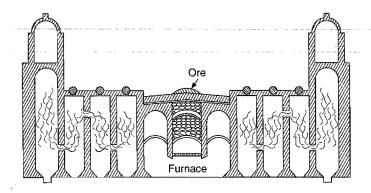

Fig. 14.17

The mercuric sulphide undergoes oxidation with evolution of sulphur dioxide. The mercuric oxide thus formed decomposes at 300°C to give mercury vapours.

$$2HgS + 3O_2 \longrightarrow 2HgO + 2SO_2$$
  
 $2HgO \longrightarrow 2Hg + O_2$ 

The vapours of mercury are condensed in a series of condensers on either side of the furnace. Most of the metal collects in the first three condensers and in the last condenser, the condensation is assisted by water spray or wet straw dust.

#### (b) The Shaft Furnace

The ore chamber is cylindrical, standing on a hexagonal base. The concentrated ore, mixed with charcoal is added to the furnace by a cup and cone arrangement. There are three fire places communicating with the chamber on the alternate sides of the hexagon. The furnace is heated to a red heat. Air is admitted along with the flames. Gases with mercury vapours, pass through iron pipes into watercooled condensers. There is an opening in the bottom of the furnace for the removal of spent ore.

The ore is sometimes mixed with lime before roasting. This helps in the oxidation of mercuric sulphide.

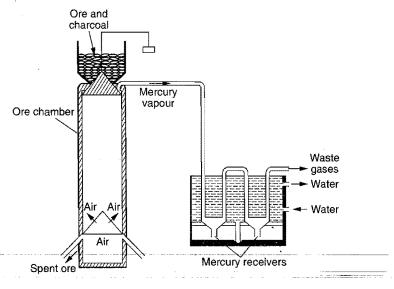

Fig. 14.18

$$HgS + CaO \longrightarrow HgO + CaS$$
  
 $2HgO \longrightarrow 2Hg + O_2$ 

- (iii) Purification: Commercial mercury is usually contaminated with other elements such as zinc, copper, lead, etc. It may be purified by the following methods.
- (a) To remove suspended particles mercury is squeezed through linen or chamois leather.
- (b) The more basic metals such as lead and zinc, which are easily oxidised, are removed as scum of their oxides when dust free air is passed through mercury at 150°C.
- (c) The mercury is dropped in a long tube filled with dilute nitric acid (about 5%). The base metals dissolve in dilute nitric acid as their nitrates.
  - (d) Further purification is done by vacuum distillation.

#### Properties

Mercury is a silvery white heavy liquid (Sp. gr. 13.6). It solidifies at -38.9°C to a white lustrous mass and boils at 357°C. Its vapour is very poisonous. It has a high surface tension and forms spherical drops easily.

It is not affected by air or oxygen at ordinary temperature but when heated at 340°C in air, it slowly combines with oxygen forming a red scum of HgO on the surface. When exposed to ozone, it gets superficially oxidised and loses its meniscus and sticks to the glass.

When rubbed with sulphur, it forms mercuric sulphide, HgS. It vigorously combines with chlorine, slowly with bromine and iodine.

It is not attacked by water and alkalies. Hydrochloric acid, dilute sulphuric acid and very dilute nitric acid have no action on mercury. Hot concentrated sulphuric acid, dilute and concentrated nitric acid dissolve it.

With conc. H<sub>2</sub>SO<sub>4</sub>:

$$H_2SO_4 \longrightarrow H_2O + SO_2 + O$$

$$Hg + H_2SO_4 + O \longrightarrow HgSO_4 + H_2O$$

$$Hg + 2H_2SO_4 \longrightarrow HgSO_4 + SO_2 + 2H_2O$$

With dilute HNO3:

$$2HNO_{3} \longrightarrow H_{2}O + 2NO + 3[O]$$

$$[2Hg + O \longrightarrow Hg_{2}O] \times 3$$

$$[Hg_{2}O + 2HNO_{3} \longrightarrow Hg_{2}(NO_{3})_{2} + H_{2}O] \times 3$$

$$6Hg + 8HNO_{3} \longrightarrow 3Hg_{2}(NO_{3})_{2} + 2NO + 4H_{2}O$$

With conc. HNO<sub>3</sub>:

$$2HNO_{3} \longrightarrow H_{2}O + 2NO_{2} + O$$

$$Hg + 2HNO_{3} + O \longrightarrow Hg(NO_{3})_{2} + H_{2}O$$

$$Hg + 4HNO_3 \longrightarrow Hg(NO_3)_2 + 2NO_2 + 2H_2O$$

Mercury is acted upon by HI on account of the formation of a complex ion  $[HgI_4]^{2-}$ .

$$Hg + 2HI \longrightarrow HgI_2 + H_2$$
  
 $HgI_2 + 2HI \longrightarrow H_2HgI_4$ 

Mercury dissolves many metals and the combinations are called amalgams. Gold, silver, tin, lead, magnesium, copper, sodium, potassium, etc., when rubbed with mercury form amalgams. Iron, cobalt and nickel do not form amalgams directly.

#### ■ Uses

Mercury is used (i) in thermometers, barometers, and other physical apparatus (ii) in the extraction of Ag and Au (iii) in the manufacture of caustic soda by the electrolytic process (iv) in the form of amalgams as reducing agents. (v) in mercury vapour lamps which give out bluish light. (vi) in making dental plastic (vii) in the manufacture of vermilon (HgS).

#### 14.24 COMPOUNDS OF MERCURY

#### Mercurous Chloride, Hg<sub>2</sub>Cl<sub>2</sub> (Calomel)

#### Preparation

(i) By adding dilute hydrochloric acid or sodium chloride solution to a mercurous salt solution, usually mercurous nitrate, a white precipitate of mercurous chloride is formed.

$$Hg_2(NO_3)_2 + 2HCl \longrightarrow Hg_2Cl_2 + 2HNO_3$$
  
 $Hg_2(NO_3)_2 + 2NaCl \longrightarrow Hg_2Cl_2 + 2NaNO_3$ 

(ii) Metallic mercury is boiled with concentrated sulphuric acid and the product, mercuric sulphate is then ground thoroughly with common salt and metallic mercury. The mixture is sublimed to separate  $Hg_2Cl_2$ .

$$\begin{aligned} & \text{Hg} + 2\text{H}_2\text{SO}_4 & \longrightarrow \text{HgSO}_4 + \text{SO}_2 + 2\text{H}_2\text{O} \\ & \text{HgSO}_4 + 2\text{NaCl} + \text{Hg} & \longrightarrow \text{Hg}_2\text{Cl}_2 + \text{Na}_2\text{SO}_4 \end{aligned}$$

(iii) It can be obtained by passing sulphur dioxide through the solution of mercuric chloride.

$$2HgCl_2 + 2H_2O + SO_2 \longrightarrow Hg_2Cl_2 + H_2SO_4 + 2HCl$$

(iv) Mercurous chloride for medicinal purposes is prepared by heating a mixture of mercuric chloride and mercury in an iron pot. The sublimate is ground and boiled with water to remove traces of mercuric chloride.

$$HgCl_2 + Hg \longrightarrow Hg_2Cl_2$$

#### Properties

- (i) It is an amorphous, tasteless, odourless white powder. It is sparingly soluble in water. It sublimes at 373°C. It is non-poisonous.
- (ii) It dissolves in hot concentrated nitric acid forming mercuric chloride and mercuric nitrate.

$$3Hg_2Cl_2 + 8HNO_3 \longrightarrow 3HgCl_2 + 3Hg(NO_3)_2 + 4H_2O + 2NO_3$$

(iii) It dissolves in chlorine water, aqua-regia or a mixture of KClO<sub>3</sub> and concentrated HCl.

$$Hg_2Cl_2 + 2Cl \longrightarrow 2HgCl_2$$

(iv) On heating, it decomposes into mercuric chloride and mercury.

$$Hg_2Cl_2 \longrightarrow Hg + HgCl_2$$

(v) When caustic soda solution is added in excess to a mercurous chloride solution in HCl, a black precipitate of mercurous oxide is formed which is decomposed under the action of light.

$$Hg_2Cl_2 + 2NaOH \longrightarrow Hg_2O + 2NaCl + H_2O$$
  
 $Hg_2O \longrightarrow HgO + Hg$ 

(vi) It turns black when treated with ammonium hydroxide. The black substance is a mixture of mercury and mercuric amino chloride.

$$Hg_2Cl_2 + 2NH_4OH \longrightarrow Hg \stackrel{NH_2}{\longleftarrow} + Hg + NH_4Cl + 2H_2O$$

(vii) It is reduced to mercury with stannous chloride.

$$SnCl_2 + Hg_2Cl_2 \longrightarrow 2Hg + SnCl_4$$

(viii) It absorbs ammonia gas and forms an addition compound.

$$Hg_2Cl_2 + 2NH_3 \longrightarrow Hg_2Cl_2 \cdot 2NH_3$$

#### ■ Uses

- (i) As a purgative in medicine.
- (ii) For making calomel electrodes.

### Mercuric Chloride (Corrosive sublimate), HgCl<sub>2</sub>

#### Preparation

(i) The compound was formerly prepared on commercial

scale by heating a mixture of mercuric sulphate with common salt. A little manganese dioxide was added to prevent the formation of any mercurous chloride. Mercuric chloride sublimes off and condenses on the cooler parts of the vessel.

$$HgSO_4 + 2NaCl \longrightarrow HgCl_2 + Na_2SO_4$$

(ii) The compound is now commercially made by heating the metal in a current of chlorine.

$$Hg + Cl_2 \longrightarrow HgCl_2$$

(iii) It can be prepared by dissolving mercuric oxide in hydrochloric acid.

$$HgO + 2HCl \longrightarrow HgCl_2 + H_2O$$

(iv) It can also be prepared by dissolving Hg or Hg<sub>2</sub>Cl<sub>2</sub> in aqua-regia.

$$3HCl + HNO_3 \longrightarrow NOCl + 2H_2O + 2Cl$$

$$Hg + 2Cl \longrightarrow HgCl_2$$

$$Hg_2Cl_2 + 2Cl \longrightarrow 2HgCl_2$$

#### Properties

- (i) It is a white crystalline compound. It is less soluble in cold water but more soluble in hot water. It behaves like a covalent compound as it is soluble in organic solvents and very slightly ionised in water.
- (ii) It has corrosive action. It is highly poisonous. It sublimes on heating. It is, therefore, known as corrosive sublimate.
- (iii) It is reduced by stannous chloride first into mercurous chloride (white) and then into mercury (black).

$$\begin{array}{c} 2 \text{HgCl}_2 + \text{SnCl}_2 \longrightarrow \text{Hg}_2 \text{Cl}_2 + \text{SnCl}_4 \\ \text{White} \\ \text{Hg}_2 \text{Cl}_2 + \text{SnCl}_2 \longrightarrow 2 \text{Hg} + \text{SnCl}_4 \\ \text{Black} \end{array}$$

(iv) When aqueous ammonia is added to the solution of mercuric chloride, a white precipitate of mercuric amino chloride is formed.

$$HgCl_2 + 2NH_4OH \longrightarrow Hg \begin{cases} NH_2 \\ Cl \end{cases} + NH_4Cl + 2H_2O$$

(v) Mercuric chloride absorbs gaseous ammonia and forms a complex salt.

$$HgCl_2 + 2NH_3 \longrightarrow Hg(NH_3)_2Cl_2$$
Mercuric diamine chloride

(vi) When H<sub>2</sub>S is passed through its solution, it forms a black precipitate of mercuric sulphide.

$$HgCl_2 + H_2S \longrightarrow HgS + 2HCl$$

(vii) When heated with sodium carbonate or sodium hydroxide in solution, a yellow precipitate of mercuric oxide is formed.

$$HgCl_2 + Na_2CO_3 \longrightarrow HgO + 2NaCl + CO_2$$
  
 $HgCl_2 + 2NaOH \longrightarrow HgO + 2NaCl + H_2O$ 

(viii) Potassium iodide forms a scarlet precipitate of mercuric iodide when added to  $HgCl_2$  solution. The precipitate of mercuric iodide dissolves in excess of potassium iodide forming a complex,  $K_2HgI_4$ .

$$HgCl_2 + 2KI \longrightarrow 2KCl + HgI_2$$
  
 $HgI_2 + 2KI \longrightarrow K_2HgI_4$ 

The alkaline solution of this complex is known as Nessler's reagent. This reagent is used for testing ammonia. When ammonia or ammonium salts are present, the brown precipitate is obtained. This precipitate is said to be the iodide of Millon's base, probably having the composition:

$$\begin{bmatrix} IHg & H \\ IHg & N \end{bmatrix}^{+} I^{-} \text{ or } \begin{bmatrix} Hg & H \\ O & N \end{bmatrix} I \cdot 2H_{2}O$$

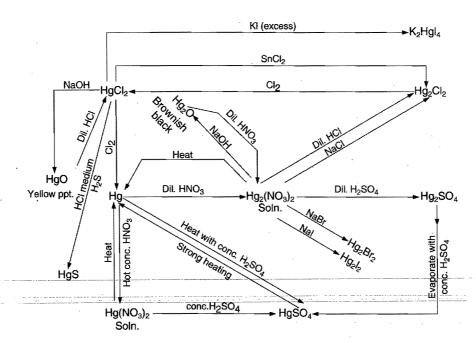

$$(B)$$

The formation of the iodide of Millon's base can be explained as follows:

#### ■ Uses

(i) It is highly poisonous and hence used as germicide. It is used as an antiseptic. A very dilute solution is employed for the sterilization of surgical instruments. (ii) For the preparation of Nessler's reagent which is used for the test of ammonia and ammonium compounds. (iii) It is used in dry cells and as a wood preservative.

**Note:** It is a strong poison, its antidote being the white of an egg which eliminates it from the system in the form of a coagulated mass.

### 14.25 PHOTOGRAPHY

The art of obtaining an exact impression of an object on a plate or paper by a chemical reaction initiated by light is called photography. It is based on the nature of silver halides. Except AgF, the silver halides are photosensitive. Silver halides, particularly silver bromide, undergo decomposition in light and turn black due to formation of free silver.

$$2AgBr \xrightarrow{Light} 2Ag + Br_2$$

The entire process of photography involves the following steps:

### 1. Preparation of photographic plate or film

An emulsion of silver bromide is prepared in a dark room by mixing silver nitrate solution with ammonium bromide solution containing gelatine with constant stirring.

$$NH_4Br + AgNO_3 \longrightarrow AgBr + NH_4NO_3$$

The emulsion is allowed to stand at about 45°C for some time so that the particles of silver bromide may grow in size. This treatment is termed as the *ripening of emulsion*. The emulsion is now cooled in ice as to solidify. It is washed with water in order to make it free from ammonium nitrate. It is warmed to melt it again.

The melted emulsion is applied uniformly on a celluloid film or smooth glass plate. Whole of this operation should be done in a dark and dust-free room.

#### 2. Exposure

The light-sensitive film or plate is loaded in a camera which is focussed on the object to be photographed. When the shutter of the camera is opened for a few seconds, the light from the object through the lens falls on the film or plate. The silver bromide is affected by light and gets activated. This is not a visible change but is called formation of *latent image*.

The light reduces silver bromide. The effect produced on the film or plate is directly proportional to the intensity of light.

$$2AgBr \rightleftharpoons 2Ag + Br_2$$

Bromine is absorbed by gelatine and helps in the decomposition of silver bromide. According to one theory (Gurney-Mott theory), the following sequence of events occur:

- (i) An incoming quantum of light hv kicks an electron out of Br to form Br and  $e^-$ .
- (ii) The electron wanders through the crystal of AgBr and eventually gets trapped at a surface defect.
- (iii) An interstitial  $Ag^+$ , such as is commonly found in AgBr, diffuses to the trap site where the  $Ag^+$  and the trapped  $e^-$  combine to give Ag.
- (iv) A second quantum of light energy hv comes along and ejects a second electron which migrates to Ag and converts it into Ag<sup>-</sup>.
- (v) A second interstitial  $Ag^+$  subsequently diffuses over and combines.

$$Ag^+ + Ag^- \longrightarrow Ag_2$$

(vi) The process repeats until a clump of about 50 silver atoms is built up. The AgBr grain is now "activated".

#### 3. Developing

The treatment of the exposed photographic film with reducing agents is called developing of the film. The chemicals used for developing as reducing agents are called developers. A developer is usually a weak reducing agent such as potassium ferrous oxalate or an alkaline solution of pyrogallol or an alkaline solution of quinol, etc.

The exposed film or plate is kept in a solution of a developer for some time. The parts activated by light are reduced to deposit more of black silver.

$$2 Ag Br + C_6 H_4 (OH)_2 \xrightarrow{} 2 Ag + 2 H Br + C_6 H_4 O_2$$

$$\underset{Quinone}{\text{Quinone}}$$

The developer does not affect those parts of the photographic film or plate which are not activated by light. On the developed film or plate the shades of the object are reversed, *i.e.*, the bright parts of the object appear dark and the dark parts appear bright. The plate or film is, therefore, called a *negative*. This operation is carried out in dark.

### 4. Fixing

In order to make the image permanent, it is necessary to remove the unreduced silver bromide from the surface of the developed film. This operation is called *fixing of image*. Fixing is done by dipping the developed film or plate in sodium thiosulphate (hypo) solution. The hypo solution dissolves the unreduced silver bromide by forming a complex.

This operation is also done in dark.

The plate is now thoroughly washed with water and dried. It can now be taken out of the dark room into light.

#### 羅 5. Printing

To get a positive image, the whole process is repeated. The Printing Out Paper (POP) or bromide paper is used. The POP has got a coating of silver bromide emulsion. The negative is placed over POP and then exposed to light for a fraction of a second. A negative of the *negative plate* or positive with respect to the actual object is obtained on the print paper. The print paper is then subjected to developing and fixing as usual. The positive print has shades exactly similar to those of the object.

#### 6. Toning

It is a technique by which different shades can be given to the printed photograph with the help of chemicals. The printed photograph obtained is black and white. This photograph is dipped in a solution containing the salt solution of either gold or platinum or selenium, etc. The dark silver particles are replaced by another metal. Thus, gold salt gives golden shade and platinum salt makes the shade bright grey.

$$\begin{array}{c} AuCl_3 + 3Ag \longrightarrow Au + 3AgCl \\ \hline \\ PtCl_4 + 4Ag \longrightarrow Pt + 4AgCl \\ \hline \\ \\ Steel \ grey \end{array}$$

The various steps involved in photography are shown in Fig. 14.19.

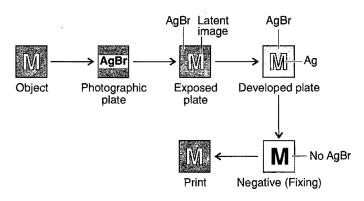

Fig. 14.19

### 14.26 f-Block Elements

28 elements from atomic number 58 to 71 (14 elements) and from atomic number 90 to 103 (14 elements) have been arranged in two horizontal rows below the periodic table. These elements are collectively called f-block elements as the last or differentiating electron in the atoms of these elements is accommodated on one of the seven f-orbitals of the antepenultimate (next to the penultimate) energy shell. These elements have also been called **inner transition elements** because the ante-penultimate energy shell, *i.e.*, (n-2)f-orbitals, lie comparatively deep within the kernel (being inner to the penultimate shell).

f-block consists of two series of elements known as Lanthanides or Lanthanons and Actinides or Actinons. The lanthanide series follows lanthanum (At. No. 57), a member of 5d-series. Similarly, actinide series comes after actinium (At. No. 89), a member of 6d-series. The 14 members of lanthanide series have been placed along with lanthanum in the third group and sixth period and similarly 14 members of the actinide series have been placed with actinium in the third group and seventh period. The justification for assigning one place to these elements has been given on the basis of their similar properties. The properties are so similar that the fifteen elements from La to Lu can be considered as equivalent to one element. The same explanation can be given in the case of actinides. In case, these elements are assigned different positions in order of their increasing atomic numbers, the symmetry of the whole arrangement would be disrupted. Due to this reason, the two series of elements, i.e., lanthanides and actinides are placed at the bottom of the periodic table and constitute one block of elements, i.e., f-block. The general electronic configuration of the f-block elements is:

$$(n-2)f^{1-14}(n-1)d^{0,1}ns^2$$
 or  $4f^{1-14}5d^{0,1}6s^2$ 

(a) 4f-series (Lanthanides): There are fourteen elements from cerium (At. No. 58) to lutetium (At. No. 71) in this series. 4f-orbitals are gradually filled up. In the past, these

elements were called **rare earths.** This name is not appropriate because many of the elements are not particularly rare. Promethium is artificial radioactive element.

**(b) 5**f-series (**Actinides**): There are fourteen elements from thorium (At. No. 90) to lawrencium (At. No. 103) in this series. 5f-orbitals are gradually filled up. The members of actinium are radioactive and majority of them are not found in nature. The elements from atomic number of 93 onwards are called transuranic elements and have been discovered by synthetic methods, *i.e.*, these are man made elements.

## 14.27

# GENERAL CHARACTERISTICS OF LANTHANIDES

The general characteristics are similar to transition metals, *i.e.*, *d*-block elements.

#### **1. Electronic configuration**

The energies of 5d- and 4f-orbitals are nearly similar and thus their fillings show certain irregularities. The electronic configurations of the atoms of the lanthanides in their ground state are given in the following table. These are the most commonly accepted configurations.

Name of the	Symbol	Atomic number	Electronic configuration	Oxidation states
Lanthanum	La	57	$[Xe]5d^16s^2$	+3
Cerium	Ce	58	$[Xe]4f^15d^16s^2$	+3, +4
Praseodymium	Pr	59	$[Xe]4f^36s^2$	+3, (+4)
Neodymium	Nd	60	$[Xe]4f^46s^2$	(+2), +3
Promethium	Pm	61	$[Xe]4f^56s^2$	(+2), +3
Samarium	Sm	62	$[Xe]4f^66s^2$	(+2), +3
Europium	Eu	63	$[Xe]4f^76s^2$	+2, +3
Gadolinium	Gd	64	$[Xe]4f^{7}5d^{1}6s^{2}$	+3
Terbium	Tb	65	$[Xe]4f^96s^2$	+3, +4
Dysprosium	Dy	66	$[Xe]4f^{10}6s^2$	+3, (+4)
Holmium	Но	67	$[Xe]4f^{11}6s^2$	+3
Erbium	Er	68	$[Xe]4f^{12}6s^2$	+3
Thulium	Tm	69	$[Xe]4f^{13}6s^2$	(+2), +3
Ytterbium	Yb	70	$[Xe]4f^{14}6s^2$	+2, +3
Lutetium	Lu	71	$[Xe]4f^{14}5d^{1}6s^{2}$	+3

The electronic configuration of lanthanum is  $[Xe]5d^16s^2$ . It is expected that 14 elements from cerium to lutetium would be formed by adding, 1, 2, 3,...14 electrons into the 4f level. However, it is energetically favourable to move the single electron on 5d into the 4f level in most of the elements but not in the cases of Ce, Gd and Lu. In Gd and Lu besides  $5d^1$ , the 4f-orbitals are half filled or fully filled. This gives extra stability to the core. The extra stability of half filled and fully filled f-orbitals is also seen in Eu( $4f^76s^2$ ) and Yb( $4f^{14}6s^2$ ).

#### 2. Oxidation states

The common stable oxidation state of all the lanthanides is +3. The oxidation states of +2 and +4 are also exhibited by some of the elements. These oxidation states are only stable in those cases where stable  $4f^0$ ,  $4f^7$  or  $4f^{14}$  configurations are achieved.

For example,  $Ce^{4+}(4f^0)$ ,  $Tb^{4+}(4f^7)$ ,  $Eu^{2+}(4f^7)$ ,  $Yb^{2+}(4f^{14})$  are stable. The oxidation states shown in parantheses in the above table are less stable. +2 or +4 oxidation states tend to revert to the more stable oxidation state of +3 by loss or gain of an electron  $Sm^{2+}$ ,  $Eu^{2+}$  and  $Yb^{2+}$  ions are thus good reducing agents in solutions while  $Ce^{4+}$ ,  $Tb^{4+}$  ions, etc., are good oxidising agents. The compounds of lanthanides are mainly ionic in nature.

# 3. Atomic and ionic radii(Lanthanide contraction)

In lanthanide series, there is a regular decrease in the atomic as well as ionic radii of trivalent ions  $(M^{3+})$  as the atomic number increases from cerium to lutetium. This decrease in size of atoms and ions is known as **Lanthanide contraction**. Although the atomic radii do show some irregularities but ionic radii decrease steadily from La to Lu. However, the decrease is very small. For example,

Element	Atomic radii (pm)	Ionic radii (pm) (M <sup>3+</sup> )
La	169	103
Ce	165	102
Pr	164	99
Nd	164	98.3
Pm		97
Sm	166	95.8
Eu	185	94.7
Gd	161	93.8
Tb	159	92.3
Dy	159	91.2
Но	158	90
Er	157	89
Tm	156	. 88
Yb	170	86.8
Lu	156	. 86

On moving from Ce to Lu, the decrease in atomic radii occurs from 165 to 156 pm, *i.e.*, the decrease is only 9 pm. Similarly, the decrease in ionic radii occurs from 102 (Ce<sup>3+</sup>) to 86 (Lu<sup>3+</sup>) pm, *i.e.*, the decrease is only 16 pm. Thus, for an increase of 14 in the atomic number, the decrease in atomic radii or ionic radii are very small in comparison to the elements of other groups and periods.

Cause of lanthanide contraction: As we proceed from one element to the next element in the lanthanide series, the nuclear charge, *i.e.*, atomic number increases by one unit and the addition of one electron occurs at the same time in 4f-energy shell. On account of the very diffused shapes of forbitals, the 4f electrons shield each other quite poorly from the nuclear charge. Thus, the effect of nuclear charge increase is somewhat more than the changed shielding effect. This brings the valence shell nearer to the nucleus and hence the size of atom or ion goes on decreasing as we move in the series. The sum of the successive reductions is equal to the total lanthanide contraction.

**Consequences of lanthanide contraction:** The main consequences of lanthanide contraction are the following:

- (i) Similar chemical properties: Since the change in the ionic radii in the lanthanide series is very small, their chemical properties are similar. Thus, it is very difficult to separate these elements in the pure state. However, lanthanide contraction brings some differences in properties like solubility, complex ion formation, hydration, etc. These differences help in the separation of lanthanide elements by fractional crystallisation or ion exchange methods.
- (ii) Basic strength of hydroxides: As the size of the lanthanide ions decreases from  $Ce^{3+}$  to  $Lu^{3+}$ , the covalent character of M—OH bond increases and hence the basic strength decreases. Thus,  $Ce(OH)_3$  is most basic while  $Lu(OH)_3$  is least basic.
- (iii) Similarity of second and third transition series: In vertical columns of transition elements, there is an increase in size from first member to second member as expected but from second member to third member, there is very small change in size and sometimes sizes are same. This is due to lanthanide contraction.

In each vertical column of transition elements, the elements of second and third transition series resemble each other more closely than the elements of first and second transition series on account of lanthanide contraction. The pairs of elements such as Zr-Hf, Mo-W, Nb-Ta, etc., possess almost the same properties.

#### 4. Physical properties

All the lanthanides are metals. They are soft, malleable and ductile in nature. They are not good conductors of heat and electricity. They are highly dense metals and their densities are in the range of 6.77 to 9.74 g cm<sup>-3</sup>. The densities and atomic

volumes, in general, increase with increase in atomic number. But a regular trend is not observed. They have fairly high melting points. However, no definite trend is observed.

#### 5. Ionisation energies

Lanthanides have fairly low ionisation energies.  $IE_1$  and  $IE_2$  values are quite comparable with the values of alkaline earth metals, particularly calcium. The sum of the first three ionisation energies in kJ mol<sup>-1</sup> for each element are given below. The values are low.

Due to low values of ionisation energies, lanthanides are highly electropositive in nature. These elements react with cold and hot water to liberate hydrogen. The reactions are, however, slow with cold water but fast with hot water.

The values of standard reduction potential ( $E^{\circ}$  values) increase from La to Lu.  $E^{\circ}$  values become less negative in the series. The values in volts are given.

All the lanthanides are, thus, strong **reducing agents.** The reducing power decreases from La to Lu.

#### **6.** Coloured ions

Many of the lanthanide ions are coloured in solid state as well as in solutions. The colour is due to partially filled f-orbitals which allow f-f transitions.  $M^{3+}$  ions having  $4f^{0}$ ,  $4f^{7}$  or  $4f^{14}$  configurations are colourless.

$$\left. \begin{array}{l} \text{La}^{3+}(4f^{\,0}) \\ \text{Gd}^{3+}(4f^{\,7}) \\ \text{Lu}^{3+}(4f^{\,14}) \end{array} \right\} \text{Colourless}$$

Pairs of  $M^{3+}$  ions having the same number of unpaired electrons in 4f-orbitals have the same colour.

$$\begin{array}{c} \Pr^{3+}(4f^2) \\ \operatorname{Tm}^{3+}(4f^{12}) \end{array} \text{ Green } \\ \operatorname{Sm}^{3+}(4f^{12}) \end{array} \begin{array}{c} \operatorname{Nd}^{3+}(4f^3) \\ \operatorname{Er}^{3+}(4f^{11}) \end{array} \text{ Pink } \\ \operatorname{Sm}^{3+}(4f^5) \\ \operatorname{Dy}^{3+}(4f^9) \end{array} \text{ Yellow } \\ \operatorname{Eu}^{3+}(4f^6) \\ \operatorname{Tb}^{3+}(4f^8) \end{array} \text{ Pale pink }$$

[Note: The cations namely  $Ce^{3+}(4f^1)$  and  $Yb^{3+}(4f^{13})$  are colourless inspite of the fact that these ions have one f-orbital singly occupied. These exceptions are difficult to explain.]

#### 7. Magnetic properties

Ions having unpaired electrons are paramagnetic while those having all the orbitals paired are diamagnetic. The lanthanide ions  $(M^{3+})$  except  $\operatorname{La}^{3+}(4f^0)$  and  $\operatorname{Lu}^{3+}(4f^{14})$  are paramagnetic since they contain 1, 2,...7 unpaired electrons.

#### 8. Chemical reactivity

All the lanthanides have almost similar chemical reactivity. The metals tarnish readily in air and on heating in  $O_2$  form oxides of the type  $M_2O_3$ . The one exception is cerium which forms  $CeO_2$  rather than  $Ce_2O_3$ . The oxides are ionic and basic.

The metals react with hydrogen but often require heating up to 300–400°C. The products are solids of formula  $MH_3$ . The hydrides are decomposed by water and react with  $O_2$ . The anhydrous halides,  $MX_3$ , can be made by heating the metal and halogen or by heating the metal oxide with the appropriate ammonium halide.

$$M_2O_3 + 6NH_4C1 \xrightarrow{300^{\circ}C} 2MCl_3 + 6NH_3 + 3H_2O$$

The fluorides are very insoluble. The chlorides are deliquescent and soluble. At elevated temperatures, lanthanides react with N, C, S, P, As, Sb and Bi. A wide variety of oxo salts are known. The carbonates, phosphates, chromates, oxalates, etc., are largely insoluble in water while nitrates, acetates, sulphates, etc., are soluble.

Because of their similar chemical reactivities, their separation from one another is very difficult.

#### 3 9. Complex formation

The lanthanides do not have much tendency to form complexes due to low charge density because of their large size. However, the tendency to form complexes and their stability increases with the increase of atomic number.

#### ■ Uses of Lanthanides

The metals are seldom used in pure state. As lanthanides do not differ much in their physical and chemical properties, these are mostly used in the form of alloys. Some common uses of lanthanides and their compounds are given below:

- (i) Misch metal (an alloy): Misch metal is an alloy consisting lanthanide metals (94–95%), iron (5%) and traces of sulphur, carbon, silicon, calcium and aluminium. The main lanthanide metals present are cerium (about 40%), lanthanum and neodymium (about 44%). These alloys are used for making ignition devices such as tracer bullets, shells and flints for lighters.
  - An alloy of magnesium and about 3% misch metal is used in making jet engine parts. Cerium-magnesium alloys are used in flash light powders.
- (ii) Cerium salts are used in dyeing cotton, in lead accumulators and as catalyst.

- (iii) Lanthanum oxide is used for polishing glass. Neodymium and praseodymium oxides are used for making coloured glasses for goggles. CeO<sub>2</sub> is used in gas mantles.
- (iv) Ceric sulphate is a well known oxidising agent in volumetric analysis.
- (v) Many lanthanide oxides are used as phosphorus in colour TV tubes.
- (vi) Various compounds of lanthanides are used as catalysts for hydrogenation, dehydrogenation, oxidation and petroleum cracking.
- (vii) The compounds of lanthanides are used in making magnetic and electronic devices for their paramagnetic and ferromagnetic properties.
- (viii) Neodymium oxide dissolved in selenium oxy-chloride is used these days as a powerful liquid laser.

# 14.28 GENERAL CHARACTERISTICS OF ACTINIDES

Excepting Ac, Th, Pa and U which occur in nature in uranium minerals, all the remaining actinides are unstable and synthetic elements. These have been made by artificial nuclear transmutations. All the actinides are radioactive. Actinides are analogous to lanthanides and involve the filling of 5f-orbitals. The following general characteristics are shown by actinides:

#### 1. Electronic configuration

In lanthanides, after lanthanum 4f-orbitals become appreciably lower in energy than the 5d-orbitals. Thus, in lanthanides the electrons fill the 4f-orbitals in a regular way with minor differences where it is possible to attain a half filled shell. Similarly, it might have been expected that after actinium the 5f-orbitals would become lower in energy than the 6d-orbitals. However, for the first four actinide elements, Th, Pa, U and Np the difference in energy between 5f and 6d-orbitals is small. Thus, in these elements (and their ions) electrons may occupy the 5f or the 6d levels or sometimes both. Later in the actinide series the 5f-orbitals do become appreciably lower in energy. Thus, from Pu onwards the 5f-shell fills in a regular way and the elements become very similar. The most widely accepted electronic configurations of actinides are tabulated below. The general electronic configurations of actinides may be written as:

$$[Rn]5f^{1-14}6d^{0,1}7s^2$$

Name of the element	Symbol	Atomic number	Electronic configuration	Oxidation states
Actinium	Ac	89	$[Rn]6d^{1},7s^{2}$	+3
Thorium	Th	90	$[Rn]6d^2,7s^2$	+3, +4
Protactinium	Pa	91	$[Rn]5f^2,6d^1,7s^2$	+3, +4, +5
Uranium	U	92	$[Rn]5f^3,6d^1,7s^2$	+3, +4, +5, +6
Neptunium	_ Np	93	$[Rn]5f^4,6d^1,7s^2$	+3, +4, +5, +6, +7

Plutonium	Pu	94	$[Rn]5f^6,7s^2$	+3, +4, +5, +6, +7
Americium	Am	95	$[Rn]5f^7,7s^2$	+2, +3, +4, +5, +6
Curium	Cm	96	$[Rn]5f^7,6d^1,7s^2$	+3, +4
Berkelium	Bk	97	$[Rn]5f^9,7s^2$	+3, +4
Californium	Cf	98	$[Rn]5f^{10},7s^2$	+2, +3
Einsteinium	Es	99	$[Rn]5f^{11},7s^2$	+2, +3
Fermium	Fm	100	$[Rn]5f^{12},7s^2$	+2, +3
Mendelevium	Md	101	$[Rn]5f^{13},7s^2$	+2, +3
Nobelium	No	102	$[Rn]5f^{14},7s^2$	+2, +3
Lawrencium	Lr	103	$[Rn]5f^{14},6d^1,7s^2$	+3

#### 2. Oxidation states

The known oxidation states of the actinide elements are shown in the above table. The actinides exhibit most common oxidation state of +3 like the lanthanides. However, this state is not always most stable as for the first four elements (Th, Pa, U and Np). For example, U<sup>3+</sup> is readily oxidised in air and in solution. +3 state is the most stable state for the later elements  $Am \rightarrow Lr$  (except No). The most stable oxidation states for the first four elements are Th (+4), Pa (+5) and U (+6). These high oxidation states involve using all the outer electrons including f electrons for bonding. Though Np shows +7 oxidation state but it is oxidising and the most stable state for Np is +5. Pu shows all the oxidation states from +3 to +7 but the most stable is +4. Am shows oxidation states from +2 to +6. Am<sup>2+</sup> has an  $f^7$  configuration. It is the analogue of Eu<sup>2+</sup> but it only exists in solid as fluoride. However, for Am and almost all the remaining elements +3 state is most stable.

+4 oxidation state exists for all the elements from Th to Bk.  $Cf^{2+}$ ,  $Es^{2+}$ ,  $Fm^{2+}$ ,  $Md^{2+}$  and  $No^{2+}$  exist as ions in solution. Their properties are like alkaline earth metals particularly  $Ba^{2+}$ . It is the most stable state for No and corresponds to an  $f^{14}$  configuration.

+5 oxidation state occurs for the elements  $Pa \to Am$ . A few solid compounds are known in +5 oxidation state but  $M^{5+}$  ions do not occur in solution. However,  $MO_2^+$  ions exist between pH 2-4. These ions disproportionate rapidly in solution.

$$2UO_{2}^{+} + 4H^{+} \longrightarrow U_{(+4)}^{4+} + UO_{2}^{2+} + 2H_{2}O$$

+6 oxidation state occurs as fluorides,  $MF_6$ , for the elements U, Np, Pu and Am. The +6 state is more widely found as the dioxoion,  $MO_2^{2+}$ . The ion is stable and exists both in solution and in crystals.

The 5f-orbitals extend into space beyond the 6s and 6p-orbitals and participate in bonding. This is in direct contrast to the lanthanides where the 4f-orbitals are buried deep inside in the atom, totally shielded by outer orbitals and thus unable to take part in bonding. The participation of the 5f-orbitals explains the higher oxidation states shown by earlier actinide elements.

The lower oxidation states tend to be ionic and the higher ones are covalent.  $M^{2+}$ ,  $M^{3+}$  and  $M^{4+}$  ions are known. Hydrolysis of these ions occurs quite readily but can be suppressed by using acid solutions. Hydrolysis of compounds in the higher oxidation states gives  $+5-MO_2^+$  ions and  $+6-MO_2^{2+}$  ions.

#### 3. Physical properties

The elements are all silvery metals. The melting points are moderately high but are considerably lower than those of transition elements. The size of the ions decreases gradually along the series because the extra charge on the nucleus is poorly screened by the f electrons. This results in an 'actinide contraction' similar to the lanthanide contraction. Actinides have high densities. Some properties of the actinides up to berkelium are tabulated below. Not much information is available about heavy actinides.

Element	Melting point (°C)	Density (g cm <sup>-3</sup> )	Radius M <sup>3+</sup> (pm)	Radius M <sup>4+</sup> (pm)
Thorium	1750	11.8	108	94
Protactinium	n 1552	15.4	104	90
Uranium	1130	19:1	102.5	89
Neptunium	640	20.5	101	87
Plutonium	640	19.9	100	86
Americium	1170	13.7	97.5	85
Curium	1340	13.5	97	85
Berkelium	986	14.8	96	83 .

#### 4. Colour of the ions

Actinide ions are generally coloured. The colour of the ions depends on the number of electrons present in 5f-orbitals. The ions having no electron in 5f-orbitals (*i.e.*, 5f<sup>0</sup>) or seven electrons in 5f-orbitals (*i.e.*, 5f<sup>7</sup>) are colourless. The ions having 2 to 6 electrons in 5f-orbitals are coloured both in the crystalline and in aqueous solution. The colour is due to f-f transition.

$${
m Th}^{4+}$$
  ${
m U}^{3+}$   ${
m Np}^{3+}$   ${
m Pu}^{3+}$   ${
m Am}^{3+}$   ${
m Cm}^{3+}$   ${
m U}^{4+}$   ${
m Np}^{4+}$   $(5f^0)$   $(5f^3)$   $(5f^4)$   $(5f^5)$   $(5f^6)$   $(5f^7)$   $(5f^2)$   $(5f^3)$  Colour- Red Purple Violet Pink Colour- Green Yellow less green

#### 5. Magnetic behaviour

Majority of the ions of the actinides possess unpaired electrons, thus they are paramagnetic in nature. Th<sup>3+</sup>(5 $f^1$ ), Pa<sup>4+</sup>(5 $f^1$ ), U<sup>3+</sup>(5 $f^3$ ), Np<sup>5+</sup>(5 $f^2$ ), Pu<sup>4+</sup>(5 $f^4$ ), Am<sup>5+</sup>(5 $f^4$ ), etc., are paramagnetic. Cations of actinides which contain only paired electrons are diamagnetic. Ac<sup>3+</sup>(5 $f^0$ ), Th<sup>4+</sup>(5 $f^0$ ), U<sup>6+</sup>(5 $f^0$ ), Lr<sup>3+</sup>(5 $f^{14}$ ), etc., are diamagnetic in nature.

#### 6. Formation of complexes

Actinides have somewhat higher tendency to form complex compounds in comparison to lanthanides. This is due to their higher charge and smaller size of their ions. Most of the halides of actinides form complex compounds with alkali metal halides. Actinides form chelates with organic compounds such as EDTA and oxine. The degree of complex formation for the ions  $M^{4+}$ ,  $MO_2^{2+}$ ,  $M^{3+}$  and  $MO_2^{+}$  decreases in the order

$$M^{4+} > MO_2^{2+} > M^{3+} > MO_2^{+}$$

#### 7. Chemical Reactivity

On account of low ionisation energies, the actinides are highly electropositive metals. They react with hot water and tarnish in air forming an oxide coating. The metals react readily with HCl but reactions with other acids are slower than expected. Concentrated HNO<sub>3</sub> makes Th, U and Pu passive. The metals react with oxygen, the halogens and hydrogen. Actinides act as strong reducing agents.

#### 8. Radioactivity

All the actinide elements are radioactive in nature.

#### **■** Uses of Actinides

Thorium, uranium and plutonium are three actinides which find uses as such or in the form of compounds.

- (i) Uses of thorium: (a) When thorium dioxide containing 1% CeO<sub>2</sub> is heated in a gas flame, it emits a brilliant white light. Because of this, it is used for making incandescent gas mantles. The mantle made from silk fibre is treated with a mixed solution of 99% thorium nitrate and 1% cerium nitrate. When this mantle is fixed in the lamp and ignited, the silk fibre burns away leaving behind a network of thoria (ThO<sub>2</sub>) and ceria (CeO<sub>2</sub>).
- (b) Naturally occurring thorium is almost entirely Th-232. This isotope is not fissionable but is converted into U-233 which is fissionable.

$$^{232}_{90}$$
Th +  $^{1}_{0}n$   $\longrightarrow$   $^{233}_{90}$ Th  $\stackrel{-\beta}{\longrightarrow}$   $^{233}_{91}$ Pa  $\stackrel{-\beta}{\longrightarrow}$   $^{233}_{92}$ U

Thus, thorium is used for the production of fissionable material needed for atomic reactors,

- (c) Thorium salts are used in medicines for the treatment of cancer.
- (ii) Uses of uranium: (a) The salts of uranium find use in glass industry (for imparting green colour), textile industry, ceramic industry and in medicines.
- (b) The U-235 isotope is used as nuclear fuel in atomic reactors and atom bombs.
- (iii) Uses of plutonium: Pu-239 is used as a nuclear fuel. It is obtained from U-238.

### 14.29

# COMPARISON OF LANTHANIDES AND ACTINIDES

Both lanthanides and actinides are f-block elements, *i.e.*, they involve filling of the f-subshell in the ante-penultimate shells of their atoms. Their general electronic configuration can be written as:

$$(n-2)f^{1-14}(n-1)d^{0,1}ns^2$$

where n = 6 for lanthanides and n = 7 for actinides. Due to similar electronic configuration, they show similarities in properties but differ also in some of their characteristics.

#### Similarities

- (i) In the atoms of the elements of both the series, three outermost shells are partly filled while the remaining innershells are completely filled. Two electrons are present in the outermost energy shell, 18 or 19 electrons are present in the penultimate energy shell  $[(n-1)s^2p^6d^{0,1}]$  and next to the penultimate shell contains 18 to 32 electrons  $[(n-2)s^2p^6d^{10}f^{1-14}]$ . However, in two elements lutetium and lawrencium the f-subshell is completely filled. These are the end members of the two series.
- (ii) The elements of both the series show mainly +3 oxidation state.
- (iii) The elements of both the series are electropositive in nature. They are reactive metals and act as strong reducing agents.
- (iv) In both the series, there is contraction in atomic and ionic  $(M^{3+}$  ions) size as the atomic number increases, *i.e.*, like lanthanide contraction, there is actinide contraction. These contractions are due to the poor shielding effect between the electrons residing in (n-2)f-orbitals.
- (v) Cations with unpaired electrons in both the series are paramagnetic.
- (vi) Most of the cations of lanthanides and actinides are coloured. The cations having same number of unpaired electrons have almost same absorption spectra. Sharp line like bands are observed in both the series. These are due to the jump of an electron from one energy level to another within (n-2)f-orbitals.
- (vii) The nitrates, perchlorates and sulphates of trivalent actinides as well as lanthanides are soluble while the hydroxides, carbonates, fluorides of the elements of both the series are insoluble.
- (viii) Ion exchange behaviour is exhibited by both actinides and lanthanides.

#### Dissimilarities

Differences in some of the characteristics of lanthanides and actinides are given in the table which is on next page.

S. No.	Lanthanides	Actinides
(i)	Except promethium, all the remaining lanthanides are non-radioactive.	All the actinides are radioactive.
(ii)	Besides +3 oxidation state, lan- thanides in some cases show +2 and +4 oxidation states.	Besides +3 oxidation state, actinides show a variety of oxidation states like +2, +4, +5, +6 and +7 also.
(iii)	anthanides do not form oxo-	Actinides form oxo-ions such as $UO_2^{2+}$ , $PuO_2^{2+}$ , $UO_2^{+}$ , $UO_2^{+}$ , etc. These ions are stable in acid and aqueous solutions.

(iv)	Oxides and hydroxides of lanthanides are less basic.	Oxides and hydroxides of actinides are more basic.
(v)		Actinides have more tendency to form complex compounds on account of high charge density.
(vi)	The magnetic nature (parama-	The magnetic nature (paramagnetic) cannot be explained easily. The observed values usually do not tally with expected values.
(vii)	Most of the tripositive ions are colourless.	Most of the tripositive and tetrapositive ions are coloured.

# 

**Example 1.** Give the number of unpaired electrons in the following:

(i) 
$$Cr^{2+}$$
 (Z = 24) (ii)  $Fe^{2+}$  (Z =

(iii) 
$$Mn^{2+}$$
 (Z = 25) (iv)  $Ti^{4+}$  (Z = 22)

llowing:  
(i) 
$$Cr^{2+}$$
 (Z = 24) (ii)  $Fe^{2+}$  (Z = 26)  
(iii)  $Mn^{2+}$  (Z = 25) (iv)  $Ti^{4+}$  (Z = 22)  
(v)  $La^{3+}$  (Z = 57) (vi)  $Zn^{2+}$  (Z = 30)  
**Solution:**

3 <i>d</i>
Electronic configuration of $Cr^{2+} = 3d^4$ $\uparrow$ $\uparrow$ $\uparrow$ $\uparrow$
Unpaired electrons = $4$ 3d
Electronic configuration of $Fe^{2+} = 3d^6$ $\uparrow \downarrow \uparrow \uparrow \uparrow \uparrow \uparrow$
Unpaired electrons = $4$ 3d
Electronic configuration of $Mn^{2+} = 3d^5$ $\uparrow$ $\uparrow$ $\uparrow$ $\uparrow$ $\uparrow$
Unpaired electrons = 5
Electronic configuration of $\text{Ti}^{4+} = 1s^2, 2s^2 2p^6, 3s^2 3p^6 3d^0, 4s^0$
Unpaired electrons = 0
Electronic configuration of $La^{3+} = 2, 8, 18, 18, 8+5d^0, 6s^0$
Unpaired electrons = 0
Electronic configuration of $Zn^{2+} = 2$ , 8, 8 + $3d^{10}$ 3d
Unpaired electrons = 0

**Example 2.** Why does Mn (II) show maximum paramagnetic character amongst the bivalent ions of the first transition series? Calculate the theoretical value of magnetic moment.

#### **Solution:**

The value of paramagnetic nature depends on the number of unpaired orbitals. Mn (II) possesses maximum number of unpaired orbitals amongst divalent ions of the first transition series and thus, possess maximum value of paramagnetic character.

Theoretical value of magnetic moment = 
$$\sqrt{n(n+2)}$$
  
=  $\sqrt{5 \times 7}$  as  $n = 5$   
=  $\sqrt{35}$  = 5.91 B.M.

#### **Example 3.** Answer the following:

- (i) Which one of  $Fe^{2+}$  and  $Fe^{3+}$  ions is more paramagnetic and why?
- (ii) Which of the following ions are expected to be coloured and why?

 $Cu^{+}$ ,  $Fe^{2+}$ ,  $Mn^{2+}$ ,  $Cr^{3+}$ ,  $Sc^{3+}$ ,  $Ti^{4+}$ 

- (iii) Name the two elements of first transition series which have abnormal electronic configuration and why?
- (iv) Name the lightest and heaviest elements in terms of density among the transition elements.
- (v) How many elements are present in each transition series? Why this number cannot be less or more?

#### **Solution:**

- (i) Fe<sup>3+</sup> is more paramagnetic than Fe<sup>2+</sup> as Fe<sup>3+</sup> consists five unpaired electrons while Fe<sup>2+</sup> possesses four unpaired electrons.
- (ii) Any ion of transition elements which possesses unpaired d electrons, i.e., d-d transition is possible shows a characteristic colour.  $(n-1)d^0$  or  $(n-1)d^{10}$  configuration does not involve d-d transition and hence, is colourless.

Fe<sup>2+</sup>, Mn<sup>2+</sup> and Cr<sup>3+</sup> are coloured, while Cu<sup>+</sup>, Sc<sup>3+</sup> and Ti<sup>4+</sup> are colourless.

Ion	Configuration	Ion	Configuration,
Cu <sup>+</sup>	$3d^{10}$ (colourless);	Cr <sup>3+</sup>	$3d^3$ (coloured)
Fe <sup>2+</sup>	$3d^6$ (coloured);	Sc <sup>3+</sup>	3d <sup>0</sup> (colourless)
Mn <sup>2+</sup>	$3d^5$ (coloured);	Ti <sup>4+</sup>	$3d^0$ (colourless)

(iii) Chromium and copper.

Chromium attains  $3d^5,4s^1$  configuration in which all the dorbitals are unpaired in order to get extra stability.

Copper attains  $3d^{10}.4s^1$  configuration in which all the dorbitals are paired in order to get extra stability.

(iv) Lightest element—Scandium; Heaviest element—Osmium

(v) Each transition series consists ten elements. This number cannot be 9 or 11 as the maximum capacity of *d*-orbitals is of 10 electrons which are gradually filled up.

1st Tr. series  $3d^{1-10}$  Ten elements 2nd Tr. series  $4d^{1-10}$  Ten elements 3rd Tr. series  $5d^{1-10}$  Ten elements

#### **Example 4.** What happens when?

- (i) Ferric chloride is added to potassium ferrocyanide.
- (ii) Iron reacts with cold dilute nitric acid. [LI.T. 1990]
- (iii) Potassium ferricyanide is added to ferrous sulphate.
- (iv) Excess of potassium iodide is added to mercuric chloride.
- (v) Green vitriol is strongly heated. [Roorkee 1990]
- (vi) Silver chloride is treated with aqueous sodium cyanide and the product thus formed is allowed to react with zinc in alkaline medium. [M.L.N.R. 1996]
- (vii)Zinc oxide is treated with excess of sodium hydroxide solution.
- (viii) Ammonium thiocyanate is added to ferric chloride solution.

#### Solution:

(i) Prussian blue is formed.

$$4\text{FeCl}_3 + 3\text{K}_4\text{Fe}(\text{CN})_6 \longrightarrow \text{Fe}_4[\text{Fe}(\text{CN})_6]_3 + 12\text{KCl}$$
Prussian blue
(Ferri ferrocyanide)

(ii) Ammonium nitrate is formed.

[Fe + 2HNO<sub>3</sub> 
$$\longrightarrow$$
 Fe(NO<sub>3</sub>)<sub>2</sub> + 2H] × 4  
HNO<sub>3</sub> + 8H  $\longrightarrow$  NH<sub>3</sub> + 3H<sub>2</sub>O  
NH<sub>3</sub> + HNO<sub>3</sub>  $\longrightarrow$  NH<sub>4</sub>NO<sub>3</sub>

$$4Fe + 10HNO_3 \longrightarrow 4Fe(NO_3)_2 + NH_4NO_3 + 3H_2O_3$$

(iii) Ferrous ion is first oxidised to ferric ion while ferricyanide ion is reduced to ferrocyanide ion. Then, ferric ions react with ferrocyanide ions to form potassium ferric ferrocyanide (Turnbull's blue).

$$Fe^{2+} + [Fe(CN)_{6}]^{3-} \longrightarrow Fe^{3+} + [Fe(CN)_{6}]^{4-}$$

$$K^{+} + Fe^{3+} + [Fe(CN)_{6}]^{4-} \longrightarrow K^{+}Fe^{3+}[Fe(CN)_{6}]^{4-}$$
Potassium ferricferrocyanide
(Turnbull's blue)

(iv) First scarlet precipitate is formed which then dissolves in excess of potassium iodide forming a complex.

$$HgCl_2 + 2KI \longrightarrow HgI_2 + 2KCl$$
 $HgI_2 + 2KI \longrightarrow K_2HgI_4$ 
Potassium tetraiodo mercurate
(colourless)

(v) When heated strongly, a mixture of gases consisting SO<sub>2</sub> and SO<sub>3</sub> is evolved and a red residue, Fe<sub>2</sub>O<sub>3</sub> is formed.

$$[FeSO_4 \cdot 7H_2O \longrightarrow FeSO_4 + 7H_2O] \times 2$$

$$2FeSO_4 \longrightarrow Fe_2O_3 + SO_2 + SO_3$$

$$SO_3 + H_2O \longrightarrow H_2SO_4$$

$$\begin{array}{c}
2\text{FeSO}_4.7\text{H}_2\text{O} \longrightarrow \text{Fe}_2\text{O}_3 + \text{SO}_2 + \text{H}_2\text{SO}_4 + 13\text{H}_2\text{O} \\
\text{Green vitriol} & \text{Red}
\end{array}$$

(vi) AgCl dissolves in KCN forming a complex, potassium argentocyanide. The addition of zinc precipitates silver.

$$\begin{array}{ccc} AgCl + 2KCN & \longrightarrow & KAg(CN)_2 + KCl \\ 2KAg(CN)_2 + Zn & \longrightarrow & K_2Zn(CN)_4 + 2Ag \\ & & Potassium \\ & zincocyanide \end{array}$$

(vii) ZnO dissolves in NaOH forming sodium zincate.

$$ZnO + 2NaOH \longrightarrow Na_2ZnO_2 + H_2O$$

(viii) Deep red colouration due to the formation of a complex is developed.

FeCl<sub>3</sub> + NH<sub>4</sub>CNS 
$$\longrightarrow$$
 Fe(CNS)Cl<sub>2</sub> + NH<sub>4</sub>Cl  
or FeCl<sub>3</sub> + 3NH<sub>4</sub>CNS  $\longrightarrow$  Fe(CNS)<sub>3</sub> + 3NH<sub>4</sub>Cl

#### **Example 5.** Explain the following:

- (i) Acidified  $K_2Cr_2O_7$  solution turns green when sodium sulphite is added to it.
- (ii) Partial roasting of sulphide ore is done in the metallurgy of copper.
  - (iii) Zinc becomes dull in moist air.
  - (iv) In the metallurgy of iron, limestone is added to the ore.
- (v) A little acid is always added in the preparation of aqueous ferrous sulphate solution.
- (vi) The addition of NaOH solution to a solution of zinc chloride produces a white precipitate which dissolves on further addition of NaOH.
- (vii) The addition of  $NH_4OH$  to  $ZnSO_4$  solution produces white precipitate but no precipitate is formed if it contains  $NH_4Cl$ .
- (viii) Mercuric chloride and stannous chloride cannot exist as such if present together in an aqueous solution.
- (ix) Zinc and not copper is used for the recovery of silver from complex  $[Ag(CN)_2]^-$ .
- (x) Why is chalcocite roasted and not calcined in the extraction of copper?
- (xi) Copper implements were known to mankind much earlier than iron implements.
- (xii) Copper sulphate dissolves in  $NH_4OH$  solution but  $FeSO_4$  does not.
  - (xiii) A ferrous salt turns brown in air.
  - (xiv) A ferrous salt decolourises acidified KMnO<sub>4</sub> solution.
  - (xv) Cadmium is used to extinguish nuclear fire.
- (xvi) Copper hydroxide is soluble in ammonium hydroxide but not in sodium hydroxide.

#### Solution:

(i) Na<sub>2</sub>SO<sub>3</sub> is a reducing agent. It reduces acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> to chromic sulphate which is green in colour.

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$
  
 $[Na_2SO_3 + [O] \longrightarrow Na_2SO_4] \times 3$ 

(ii) The concentrated ore is roasted in reverberatory furnace in a current of air. The volatile impurities such as free sulphur, arsenic and antimony are removed as volatile oxides and the ore is partially oxidised.

$$4As + 3O_2 \longrightarrow 2As_2O_3$$

$$4Sb + 3O_2 \longrightarrow 2Sb_2O_3$$

$$S + O_2 \longrightarrow SO_2$$

$$2CuFeS_2 + O_2 \longrightarrow Cu_2S + 2FeS + SO_2$$

$$2CuFeS_2 + 4O_2 \longrightarrow Cu_2S + 2FeO + 3SO_2$$

$$2Cu_2S + 3O_2 \longrightarrow 2Cu_2O + 2SO_2$$

A mixture of sulphides and oxides is formed. The Cu<sub>2</sub>O so formed reacts with unconverted Cu<sub>2</sub>S to form copper.

$$Cu_2S + 2Cu_2O \longrightarrow 6Cu + SO_2$$

(iii) When zinc is exposed to moist air, the surface is affected with the formation of a film of basic zinc carbonate on it. Due to this zinc becomes dull.

$$\begin{array}{c} [2Zn + 2H_2O + O_2 \longrightarrow 2Zn(OH)_2] \times 2 \\ Zn(OH)_2 + CO_2 \longrightarrow ZnCO_3 + H_2O \\ ZnCO_3 + 3Zn(OH)_2 \longrightarrow ZnCO_3 \cdot 3Zn(OH)_2 \\ \hline 4Zn + 3H_2O + CO_2 + 2O_2 \longrightarrow ZnCO_3 \cdot 3Zn(OH)_2 \\ Basic zinc carbonate \\ \end{array}$$

(iv) Limestone is added as a flux. It is decomposed in the furnace into CaO and CO<sub>2</sub>. CaO reacts with gangue silica and forms infusible slag, CaSiO<sub>3</sub>.

$$\begin{array}{c} \text{CaCO}_{3} \longrightarrow \text{CaO} + \text{CO}_{2} \\ \text{CaO} + \text{SiO}_{2} \longrightarrow \text{CaSiO}_{3} \\ \text{Slag} \end{array}$$

(v) Ferrous sulphate is a salt of a weak base and a strong acid. Thus, its hydrolysis occurs when it is dissolved in water and solution becomes turbid due to formation of ferrous hydroxide.

$$FeSO_4 + 2H_2O \implies Fe(OH)_2 + H_2SO_4$$

Addition of a small amount of acid shifts the equilibrium towards left and thus prevents hydrolysis.

(vi) On addition of NaOH, a white precipitate of Zn(OH)<sub>2</sub> is formed which dissolves in excess of NaOH forming sodium zincate.

$$\begin{split} ZnCl_2 + 2NaOH &\longrightarrow Zn(OH)_2 + 2NaCl \\ Zn(OH)_2 + 2NaOH &\longrightarrow Na_2ZnO_2 + 2H_2O \\ &\quad Soluble \end{split}$$

(vii) NH<sub>4</sub>OH is a weak hydroxide. It ionises slightly furnishing OH<sup>-</sup> ions. However, the OH<sup>-</sup> ions are sufficient to cause the precipitation of Zn(OH)<sub>2</sub> as its solubility product is exceeded.

$$ZnSO_4 + 2NH_4OH \longrightarrow Zn(OH)_2 + (NH_4)_2SO_4$$
 White ppt.

In presence of NH<sub>4</sub>Cl, the ionisation of NH<sub>4</sub>OH is further suppressed and sufficient OH<sup>-</sup> ions are not available to cause precipitation as the solubility product is not exceeded.

(viii) HgCl<sub>2</sub> is an oxidising agent while SnCl<sub>2</sub> is a reducing agent. When both are present, a redox reaction occurs forming Hg and stannic chloride as final products.

$$\begin{array}{c} SnCl_2 + 2HgCl_2 \longrightarrow Hg_2Cl_2 + SnCl_4 \\ White \\ Hg_2Cl_2 + SnCl_2 \longrightarrow 2Hg + SnCl_4 \\ Black \ or \ grey \end{array}$$

(ix) Zinc is cheaper as well as stronger reducing agent in comparison to copper.

$$Zn + 2[Ag(CN)_2]^- \longrightarrow 2Ag + [Zn(CN)_4]^{2-}$$

(x) Air is necessary to convert impurities such as sulphur, arsenic and antimony into volatile oxides and for partial oxidation of the pyrite ore. Calcination does not use oxygen while roasting is done in presence of air. Thus, roasting and not calcination is done in the metallurgy of copper.

See reactions in answer (ii).

- (xi) Copper occurs in nature also as a free metal but iron is always found in nature in combined state. The technology to manufacture iron was developed much later. Hence iron implements were used later than copper implements as copper was known in the early times.
- (xii) Copper sulphate dissolves in the ammonium hydroxide due to formation of a copper complex. Ferrous sulphate reacts with NH<sub>4</sub>OH to form insoluble Fe(OH)<sub>2</sub>. It does not form any complex with NH<sub>4</sub>OH.

$$\begin{array}{c} CuSO_4 + 4NH_4OH \longrightarrow [Cu(NH_3)_4]SO_4 + 4H_2O \\ & \text{Deep blue solution} \end{array}$$
 
$$FeSO_4 + 2NH_4OH \longrightarrow Fe(OH)_2 + (NH_4)_2SO_4$$
 Insoluble

(xiii) A ferrous salt turns brown in air due to oxidation to ferric salt.

(xiv) Ferrous salt acts as a reducing agent. It reduces acidified KMnO<sub>4</sub> into K<sub>2</sub>SO<sub>4</sub> and MnSO<sub>4</sub> which form colourless solution, *i.e.*, decolourisation of KMnO<sub>4</sub> solution takes place.

$$\begin{array}{c} 2KMnO_4 + 3H_2SO_4. \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O] \\ \underline{ [2FeSO_4 + H_2SO_4 + [O] \longrightarrow Fe_2(SO_4)_3 + H_2O] \times 5} \\ \hline 2KMnO_4 + 10FeSO_4 + 8H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 \\ + 5Fe_2(SO_4)_3 + 8H_2O \\ \end{array}$$

(xv) Cadmium absorbs neutrons, stops nuclear fission reaction and extinguishes nuclear fire.

(xvi)  $Cu(OH)_2$  dissolves in  $NH_4OH$  by forming a complex.  $Cu(OH)_2 + 4NH_4OH \longrightarrow [Cu(NH_3)_4](OH)_2 + 4H_2O$  $Cu(OH)_2$  is insoluble in NaOH as no such complex is formed.

#### **Example 6.** Explain the following:

- (i) Magnesium oxide is used for lining of steel making furnace.
  - (ii) Cast iron is hard but pure iron is soft in nature.
  - (iii)  $Fe^{3+}$  is more stable than  $Fe^{2+}$ .

- (iv) Anhydrous FeCl<sub>3</sub> cannot be obtained by heating hydrated ferric chloride.
  - (v) The compounds of iron are coloured and paramagnetic.
  - (vi) Mercuric chloride is called corrosive sublimate.
- (vii) The colour of mercurous chloride changes from white to black when treated with ammonia solution.
  - (viii) Excess of carbon is added in the zinc metallurgy.
- (ix) Zinc readily liberates hydrogen from cold dilute  $H_2SO_4$  but not from cold concentrated  $H_2SO_4$ .
  - (x) The compounds of Zn, Cd and Hg are usually white.
- (xi) A dark blue precipitate is formed when sodium hydroxide solution is added to copper sulphate solution. The precipitate darkens on heating.
- (xii) Cuprous chloride is insoluble in water and dilute HCl but dissolves in concentrated HCl.
- (xiii) CuS is not precipitated by passing  $H_2S$  through copper sulphate solution containing KCN.
  - (xiv) Silver nitrate solution is kept in dark coloured bottles. **Solution:**
- (i) MgO is basic in nature. It removes acidic impurities present in cast iron used for making steels.

$$MgO + SiO_2 \longrightarrow MgSiO_3$$
  
 $Slag$   
 $3MgO + P_2O_5 \longrightarrow Mg_3(PO_4)_2$ 

MgO is also a refractory material as it can tolerate very high temperature of the furnace.

- (ii) Cast iron consists carbon 2.5 to 5% which is responsible for its hardness.
- (iii) Fe<sup>3+</sup> has the configuration [Ar] $3d^5$ , *i.e.*, all the five d-orbitals are singly occupied which is a stable configuration in accordance to Hund's rule of maximum multiplicity while the configuration of Fe<sup>2+</sup> is [Ar]  $3d^6$  in which one orbital is doubly occupied and rest of the four orbitals are singly occupied. It is not so stable configuration as it is unsymmetrical in nature.
- (iv) On heating hydrated ferric chloride, anhydrous ferric chloride is not formed as water of crystallisation reacts to form  $Fe_2O_3$  and HCl.
- (v) Iron compounds either has  $Fe^{2+}$  or  $Fe^{3+}$  ions and each contains unpaired orbitals which show paramagnetic character. d-d transition is possible. Hence, the compounds are coloured.
- (vi) HgCl<sub>2</sub> is poisonous (corrosive) in nature. It undergoes sublimation. Due to these properties, it is called corrosive sublimate.
- (vii) Hg<sub>2</sub>Cl<sub>2</sub> reacts with NH<sub>3</sub> to form a mixture of mercury and mercuric amino chloride which is a black substance.

$$\begin{array}{ccc} Hg_2Cl_2 + NH_3 & \longrightarrow & \underbrace{Hg + Hg(NH_2)Cl}_{Black} + HCl \end{array}$$

- (viii) Carbon has to play a double role,
  - (a) It reduces zinc oxide to zinc.

. 
$$ZnO + C \longrightarrow Zn + CO$$
  
 $ZnO + CO \longrightarrow Zn + CO_2$ 

- (b) It reduces  $CO_2$  into CO which is used as a fuel  $CO_2 + C \longrightarrow 2CO$
- (ix)  $H_2SO_4$  is a covalent compound. Conc.  $H_2SO_4$  does not contain  $H_3O^+$  ions while dilute  $H_2SO_4$  consists  $H_3O^+$  ions which react with zinc to liberate hydrogen.

$$H_2SO_4 + 2H_2O \implies 2H_3O^+ + SO_4^{2-}$$
  
 $Zn + 2H_3O^+ \longrightarrow Zn^{2+} + H_2 + 2H_2O$ 

- (x) In the compounds of zinc metals,  $M^{2+}$  ions possess the penultimate *d*-orbitals doubly occupied, *i.e.*,  $(n-1)d^{10}$  configuration. There is no d-d transition. Hence, the compounds of zinc metals are colourless.
- (xi) NaOH reacts with CuSO<sub>4</sub> when dark blue precipitate of Cu(OH)<sub>2</sub> is formed. This precipitate on heating forms CuO which is black in colour. Hence, the colour darkens on heating.

$$\begin{array}{c} \text{CuSO}_4 + 2\text{NaOH} & \longrightarrow \text{Cu(OH)}_2 + \underbrace{\text{Na}_2\text{SO}_4}_{\text{Blue}} \\ \text{Cu(OH)}_2 & \longrightarrow \text{CuO}_{\text{Black}} + \text{H}_2\text{O} \end{array}$$

(xii) Cu<sub>2</sub>Cl<sub>2</sub> dissolves in conc. HCl due to the formation of a copper complex.

$$Cu_2Cl_2 + 2HCl \longrightarrow 2H[CuCl_2]$$

(xiii) CuSO<sub>4</sub> forms a complex with KCN.

$$CuSO_4 + 2KCN \longrightarrow Cu(CN)_2 + K_2SO_4$$

$$2Cu(CN)_2 \longrightarrow Cu_2(CN)_2 + (CN)_2$$

 $Cu_2(CN)_2+6KCN \longrightarrow 2K_3Cu(CN)_4 \Longrightarrow 6K^++2[Cu(CN)_4]^{3-}$  $K_3Cu(CN)_4$  complex does not furnish  $Cu^{2+}$  ions. Hence, no precipitate of CuS is formed when  $H_2S$  is passed through

solution.

(xiv) AgNO<sub>3</sub> is photosensitive. It decomposes in presence of light. To prevent its decomposition, it is kept in coloured bottles as these do not permit light to pass through.

#### **Example 7.** Explain the following:

- (i) Copper (I) salts are not known in aqueous solutions.
- (ii) Ferric iodide is very unstable but ferric chloride is not.
- (iii) Silver bromide is used in photography.
- (iv) Anode mud in copper refining contains silver and gold.
- (v) Silver fluoride is fairly soluble in water while other silver halides are insoluble.
- (vi) Copper is regarded as transition metal though it has completely filled d-orbital (d<sup>10</sup>). [M.L.N.R. 1994]
- (vii) Out of cobalt and zinc salts, which is attracted in a magnetic field? [Roorkee 1995]
  - (viii) The species  $[CuCl_4]^{2-}$  exist but  $[Cul_4]^{2-}$  does not.
  - (ix) Copper is largely used in electrical wiring.
  - (x) A solution of  $K_2CrO_4$  changes colour on being acidified. **Solution:**
- (i) Cu (I) salts undergo disproportionation in aqueous solution.

$$2Cu^+ \longrightarrow Cu^{2+} + Cu$$

(ii) I<sup>-</sup> ion is a stronger reducing agent in comparison to Cl<sup>-</sup> ion. Fe<sup>3+</sup> is easily reduced by iodide ion.

$$2Fe^{3+} + 2I^{-} \longrightarrow 2Fe^{2+} + I_{2}$$

- (iii) AgBr is sensitive to light. It is converted into metallic silver grains when light is incident on it.
- (iv) Silver and gold are less basic than copper. These are not ionised under the applied voltage and get deposited in the anodic mud.
- (v) The hydration energy of AgF is higher than its lattice energy. Hence, it is soluble in water. The hydration energy values of other halides are smaller than their lattice energy values. Hence, these halides are insoluble in water.
- (vi) Although copper has  $3d^{10}$  configuration yet it can lose one electron from this arrangement. Thus,  $Cu^{2+}$  ion has  $3d^9$  configuration. So, according to the definition that transition metal cations have partially filled (n-1)d-subshell, copper is regarded as a transition metal.
- (vii) Of cobalt and zinc salts, the cobalt salts are attracted in a magnetic field, because cobalt ion containing unpaired electrons is characterised by a permanent magnetic moment.  $Zn^{2+}$  ion contains  $3d^{10}$  configuration, *i.e.*, no unpaired electrons, so zinc salts are not attracted in magnetic field.
- (viii) I<sup>-</sup> ion is a stronger reducing agent than CI<sup>-</sup> ion. It reduces Cu<sup>2+</sup> ion into Cu<sup>+</sup> ion. Hence, cupric iodide is converted into cuprous iodide. Thus, the species [CuI<sub>4</sub>]<sup>2-</sup> does not exist.
- (ix) Copper is a very good conductor of electricity. Moreover, it is not easily affected by the atmosphere.
- (x) On being acidified, the chromate ions dimerise to form dichromate ions which are orange coloured. Thus,

**Example 8.** How the following conversions are made? Explain only by giving chemical equations.

- (i) Copper chloride from copper nitrate.
- (ii) Cuprous oxide from copper sulphate.
- (iii) Cuprous oxide from copper.
- (iv) Mercuric chloride from mercuric sulphate.
- (v) Anhydrous ZnCl<sub>2</sub> from white vitriol.
- (vi) Zinc carbonate from zinc oxide.
- (vii) Ferrous sulphate from ferrous ammonium sulphate.
- (viii) Prussian blue from K<sub>4</sub>Fe(CN)<sub>6</sub>.
- (ix) Lithopone from white vitriol.
- (x) Cuprous iodide from copper sulphate.

#### Solution:

(i) 
$$Cu(NO_3)_2 + 2NaOH \longrightarrow Cu(OH)_2 + 2NaNO_3$$

(ii) 
$$Cu(OH)_2 + 2HCI \longrightarrow CuCl_2 + 2H_2O$$
  
 $CuSO_4 + 2NaOH \longrightarrow Cu(OH)_2 + Na_2SO_4$ 

$$Cu(OH)_2 \xrightarrow{Strongly} CuO + H_2O$$

$$\begin{array}{cccc} \text{CuO} + \underset{\text{Powder}}{\text{Cu}} & \xrightarrow{\text{Heat}} & \text{Cu}_2\text{O} \\ \\ \text{or} & \text{CuSO}_4 & \longrightarrow & \text{Fehling's solution} \\ \text{C}_6\text{H}_{12}\text{O}_6 + & \text{Fehling's soln.} & \longrightarrow & \text{Cu}_2\text{O} + \text{C}_6\text{H}_{12}\text{O}_7 \\ \\ \text{Glucose} & \text{Red ppt. Gluconic acid} \\ \\ \text{(iii)}\text{Cu} + & \text{4HNO}_3 \text{ (conc.)} & \longrightarrow & \text{Cu}(\text{NO}_3)_2 + 2\text{NO}_2 + 2\text{H}_2\text{O} \\ \\ & & 2\text{Cu}(\text{NO}_3)_2 & \xrightarrow{\text{Heat}} & 2\text{CuO} + 4\text{NO}_2 + \text{O}_2^\circ \\ \\ & & \text{CuO} + \text{Cu} & \xrightarrow{\text{Heat}} & \text{Cu}_2\text{O} \end{array}$$

(iv) By heating a solid mixture of HgSO<sub>4</sub> and NaCl.

$$HgSO_4 + 2NaCl \xrightarrow{Heat} HgCl_2 + Na_2SO_4$$

(v) 
$$ZnSO_4.7H_2O \xrightarrow{Strongly} ZnSO_4 + 7H_2O$$
White vitriol  $\xrightarrow{heated} Anhydrous$ 

$$ZnSO_4 \xrightarrow{Heat} ZnO + SO_3 ...$$
  
 $ZnO + 2HCl \longrightarrow ZnCl_2 + H_2O$ 

$$ZnCl_2 + 2NH_4Cl \xrightarrow{\hspace*{1cm}} ZnCl_2 \cdot 2NH_4Cl \xrightarrow{\hspace*{1cm} Double \hspace*{1cm} salt}$$

$$ZnCl_2 \cdot 2NH_4Cl \xrightarrow{\text{Heat} \atop \text{HCl gas}} ZnCl_2 + 2NH_4Cl$$
Anhydrous

(vi) 
$$ZnO + H_2SO_4 \longrightarrow ZnSO_4 + H_2O$$
  
 $ZnSO_4 + 2NaHCO_3 \longrightarrow ZnCO_3 + Na2SO4 + H2O + CO2$ 

(vii) 
$$FeSO_4$$
·(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>·6H<sub>2</sub>O + 4NaOH  $\longrightarrow$   
 $Fe(OH)_2 + 2NH_3 + 2Na_2SO_4 + 8H_2O$ 
ppt.

$$Fe(OH)_2 + H_2SO_4 \longrightarrow FeSO_4 + 2H_2O$$

The solution is put to crystallisation when crystals of ferrous sulphate, FeSO<sub>4</sub>·7H<sub>2</sub>O, are obtained.

(viii) 
$$4\text{FeCl}_3 + 3\text{K}_4\text{Fe}(\text{CN})_6 \longrightarrow \text{Fe}_4[\text{Fe}(\text{CN})_6]_3 + 12\text{KCl}$$
  
Prussian blue

(ix) 
$$ZnSO_4 + BaS \longrightarrow ZnS + BaSO_4$$
  
Lithopone

$$(x) \qquad \qquad 2CuSO_4 + 4KI \longrightarrow Cu_2I_2 + 2K_2SO_4 + I_2$$
 White ppt.

**Example 9.** A metal chloride (x) shows the following reactions:

- (a) When  $H_2S$  is passed in an acidified solution of (x) a black precipitate is obtained.
- (b) The black precipitate is not soluble in ammonium sulphide.
- (c) The solution of stannous chloride is added to an aqueous solution of (x), a white precipitate is obtained which turns grey on addition of more stannous chloride.
- (d) When aqueous solution of KI is added to an aqueous solution of (x), a red precipitate is obtained which dissolves on addition of excess of KI.

Identify (x) and write down the equations for the reactions.

[Roorkee 1991]

#### **Solution:**

The acidified solution of (x) gives a black sulphide with  $H_2S$  indicates that the chloride is of a basic cation of second group.

The sulphide is insoluble in ammonium sulphide, hence, the cation belongs to IIA group of mixture analysis.

It gives white precipitate with  $SnCl_2$  which turns to grey in excess of  $SnCl_2$  suggests that (x) is  $HgCl_2$ . It is further confirmed by the reaction with KI.

$$\begin{array}{c} \textbf{Reactions} \ : \ HgCl_2 + H_2S \longrightarrow \underset{Black}{HgS} + 2HCl \\ & Black \\ \\ 2HgCl_2 + SnCl_2 \longrightarrow \underset{White}{Hg_2Cl_2} + SnCl_4 \\ & White \\ \\ Hg_2Cl_2 + SnCl_2 \longrightarrow 2Hg + SnCl_4 \\ & Grey \\ \\ HgCl_2 + 2KI \longrightarrow \underset{Red \ ppt.}{HgI_2} + 2KCl \\ & Red \ ppt. \\ \\ HgI_2 + 2KI \longrightarrow \underset{Soluble}{K_2HgI_4} \\ & Soluble \\ \end{array}$$

**Example 10.** A certain inorganic compound (A) on heating loses its water of crystallisation. On further heating, a blackish brown powder (B) and two oxides of sulphur (C and D) are obtained. The powder (B) on boiling with hydrochloric acid gives a yellow solution (E). When H<sub>2</sub>S is passed in (E), a white turbidity (F) and apple green solution (G) are obtained. The solution (E) on treatment with thiocyanate ions gives a blood red coloured compound (H). Identify the compounds from (A) to (H).

#### **Solution:**

The compound (A) on strong heating gives two oxides of sulphur, it may be a sulphate. The solution (E) on treatment with thiocyanate ions gives blood red coloured compound (H) indicates that the solution (E) consists  $Fe^{3+}$  ions. Thus, the compound (A) is ferrous sulphate,  $FeSO_4.7H_2O$ .

#### Reactions:

$$\begin{array}{c} \text{FeSO}_4 \cdot 7\text{H}_2\text{O} \xrightarrow{-7\text{H}_2\text{O}} \text{FeSO}_4 \xrightarrow{\text{Heat}} \text{Fe}_2\text{O}_3 + \text{SO}_2 + \text{SO}_3 \\ (B) & (C) & (D) \\ & & \text{Blackish} \\ & \text{brown powder} \end{array}$$
 
$$\begin{array}{c} \text{Fe}_2\text{O}_3 + 6\text{HCl} \longrightarrow 2\text{FeCl}_3 + 3\text{H}_2\text{O} \\ (B) & (E) \\ & \text{Yellow solution} \end{array}$$
 
$$2\text{FeCl}_3 + \text{H}_2\text{S} \longrightarrow 2\text{FeCl}_2 + 2\text{HCl} + \text{S} \\ (G) & (F) \\ & \text{Apple} & \text{White} \\ & \text{green solution} & \text{turbidity} \end{array}$$
 
$$\begin{array}{c} \text{FeCl}_3 + 3\text{CNS}^- \longrightarrow \text{Fe}(\text{CNS})_3 + 3\text{Cl}^- \\ & \text{Blood red} \\ & \text{coloured solution} \end{array}$$

**Example 11.** (i) A black mineral (A) on treatment with dilute sodium cyanide solution in presence of air gives a clear solution of (B) and (C).

- (ii) The solution (B) on reaction with zinc gives precipitate of a metal (D).
- (iii) (D) is dissolved in dilute  $HNO_3$  and the resulting solution gives a white precipitate (E) with dilute HCl.
  - (iv) (E) on fusion with sodium carbonate gives (D).

(v) (E) dissolves in ammonia solution giving a colourless solution of (F). Identify (A) to (F) and give chemical equations for reactions at steps (i) to (v). [Roorkee 1995]

#### **Solution:**

On the basis of the given data, the black mineral (A) is silver glance, Ag<sub>2</sub>S. It is confirmed by the following:

(i) It dissolves in sodium cyanide solution in presence of air.

$$\begin{array}{c} \operatorname{Ag_2S} + 4\operatorname{NaCN} + 2\operatorname{O}_2 \longrightarrow 2[\operatorname{NaAg}(\operatorname{CN})_2] + \operatorname{Na_2SO_4} \\ \operatorname{Sodium} \\ \operatorname{argento\ cyanide} \\ \operatorname{(B)} \\ \operatorname{(C)} \\ \operatorname{Sodium} \\ \operatorname{sulphate} \\ \operatorname{(C)} \\ \operatorname{Sodium} \\ \operatorname{sulphate} \\ \operatorname{(C)} \\ \operatorname{(E)} \\ \operatorname{(D)} \\ \operatorname{AgR}(\operatorname{CN})_2] + \operatorname{Zn} \longrightarrow \operatorname{Na_2Zn}(\operatorname{CN})_4 + 2\operatorname{Ag} \\ \operatorname{(D)} \\ \operatorname{AgR}(\operatorname{CN})_2] + \operatorname{Zn} \longrightarrow \operatorname{Na_2Zn}(\operatorname{CN})_4 + 2\operatorname{Ag} \\ \operatorname{(D)} \\ \operatorname{AgR}(\operatorname{CN})_2] + \operatorname{Zn} \longrightarrow \operatorname{AgR}(\operatorname{CN})_4 + 2\operatorname{Ag} \\ \operatorname{(D)} \\ \operatorname{AgR}(\operatorname{CN})_2 + \operatorname{AgR}(\operatorname{CN})_3 + \operatorname{NO} + 2\operatorname{H_2O} \\ \operatorname{(D)} \\ \operatorname{AgCl} + \operatorname{Na_2CO_3} \longrightarrow \operatorname{AgCl} + \operatorname{HNO_3} \\ \operatorname{(E)} \\ \operatorname{(D)} \\ \operatorname{AgCl} + \operatorname{2NH_4OH} \longrightarrow \operatorname{Ag}(\operatorname{NH_3})_2\operatorname{Cl} + 2\operatorname{H_2O} \\ \operatorname{(E)} \\ \operatorname{(E)} \\ \operatorname{(Colourless\ solution} \\ \end{array}$$

- (A) = Silver glance, Ag<sub>2</sub>S
- (B) = Sodium argentocyanide, NaAg(CN)<sub>2</sub>
- (C) = Sodium sulphate, Na<sub>2</sub>SO<sub>4</sub>
- (D) = Silver metal, Ag
- (E) = Silver chloride, AgCl
- (F) = Diamminosilver (I) chloride,  $Ag(NH_3)_2Cl$

**Example 12.** (i) A black coloured compound (B) is formed on passing hydrogen sulphide through the solution of a compound (A) in  $NH_4OH$ .

- (ii) (B) on treatment with HCl and potassium chlorate gives A.
- (iii) (A) on treatment with potassium cyanide gives a buff coloured precipitate which dissolves in excess of this reagent forming a compound (C).
- (iv) The compound (C) is changed into a compound (D) when its aqueous solution is boiled.
- (v) The solution of (A) was treated with excess of sodium bicarbonate and then with bromine water. On cooling and shaking for sometime, a green coloured compound (E) is formed. No change is observed on heating. Identify (A) to (E) and give chemical equations at steps (i) to (v). [Roorkee 1996]

#### **Solution:**

The formation of a black coloured precipitate on passing  $H_2S$  in alkaline medium indicates that the salt is either of cobalt or nickel. However, the reaction (iii) suggests that (A) is a cobalt salt (CoCl<sub>2</sub>). This is confirmed by the following reactions:

(i) 
$$CoCl_2+H_2S+2NH_4OH \longrightarrow CoS + 2NH_4Cl + 2H_2O$$
(B)
(B)

(ii) 
$$CoS + 2HCl + [O] \longrightarrow CoCl_2 + H_2O$$
  
(B) From  $KClO_3$  (A)

(iii) 
$$CoCl_2 + 2KCN \longrightarrow 2KCl + Co(CN)_2$$
 $Buff coloured$ 
 $Co(CN)_2 + 4KCN \longrightarrow K_4Co(CN)_6$ 
(iv)  $2K_4Co(CN)_6 + H_2O + [O] \longrightarrow 2K_3Fe(CN)_6 + 2KOH$ 
 $CO \longrightarrow From \ air \ (D)$ 
Pot. cobaltocyanide Pot. cobalticyanide
(v)  $CoCl_2 + 2NaHCO_3 \longrightarrow Co(HCO_3)_2 + 2NaCl$ 
 $Co(HCO_3)_2 + 4NaHCO_3 \longrightarrow Na_4Co(CO_3)_3 + 3CO_2 + 3H_2O$ 
 $Br_2 + H_2O \longrightarrow 2HBr + [O]$ 
 $2Na_4Co(CO_3)_3 + H_2O + [O] \longrightarrow 2Na_3Co(CO_3)_3 + 2NaOH$ 

(E) is stable towards heat.

Example 13. When the ore haematite is burnt in air with coke around 2000°C along with lime, the process not only produces steel but also produces a silicate slag that is useful in making building materials such as cement. Discuss the same and show through balanced chemical equations. [I.I.T. 1998] [Hint: Haematite (Fe<sub>2</sub>O<sub>3</sub>) on burning with coke and lime at 2000°C results in the following:

Green coloured solution

$$\begin{array}{c} C + O_2 \longrightarrow CO_2 \\ CO_2 + C \longrightarrow 2CO \\ \end{array}$$

$$Fe_2O_3 + 3CO \longrightarrow 2Fe + 3CO_2 \\ Steel \\ SiO_2 + CaO \longrightarrow CaSiO_3 \\ Lime & Slag \end{array}$$

(used as a building material)]

Example 14. An aqueous solution containing 1 mole of  $HgI_2$  and 2 moles of NaI is orange in colour. On addition of excess of NaI the solution becomes colourless. The orange colour reappears on subsequent addition of NaOCl. Explain with equations. [I.I.T. 1999]

[Hint: HgI<sub>2</sub> is sparingly soluble in water and gives orange solution. On addition of excess of NaI, the colourless soluble complex Na<sub>2</sub>HgI<sub>4</sub> is formed.

$$HgI_2 + 2NaI \longrightarrow Na_2HgI_4$$

The complex reacts with NaOCl with formation of again HgI<sub>2</sub>, *i.e.*, orange colour is restored.

 $3 \text{Na}_2 \text{HgI}_5 + 2 \text{NaOCl} + 2 \text{H}_2 \text{O} \longrightarrow 3 \text{HgI}_2 + 2 \text{NaCl} + 4 \text{NaOH} + 2 \text{NaI}_3]$ 

#### Example 15. Explain:

- (i) Why are Sm<sup>2+</sup>, Eu<sup>2+</sup> and Yb<sup>2+</sup> good reducing agents?
- (ii) Can lanthanum (Z = 57) exhibit +4 oxidation state?
- (iii) Why are +3 oxidation state of gadolinium (Z = 64) and lutetium (Z = 91) especially stable?
  - (iv) Why do Zr and Hf exhibit similar properties?

#### **Solution:**

(i) The most stable oxidation state of lanthanides is +3. Hence, ions in +2 state tend to change to +3 oxidation state by loss of electron and act as reducing agents.

- (ii)  $La^{3+}$  has a stable configuration of an inert gas  $[(Xe)5d^06s^0]$ , *i.e.*, xenon (54—2, 8, 18, 18, 8). To obtain +4 oxidation state, the stable configuration is to be disturbed which is not possible under ordinary conditions and hence  $La^{4+}$  does not exist.
- (iii) This is because gadolinium in +3 state has half filled 4f-subshell  $(4f^7)$  and lutetium in +3 state has completely filled 4f-subshell which are very stable configurations.
- (iv) Due to lanthanide contraction, the atomic radii of both Zr and Hf are same. Hence, their properties are similar.

**Example 16.** Why is dilute sulphuric acid and not dilute HCl or HNO<sub>3</sub> used to acidify a permanganate solution in volumetric analysis?

#### **Solution:**

Volumetric titrations involving potassium permanganate solution are carried out only in presence of dilute H<sub>2</sub>SO<sub>4</sub> but not in presence of dilute HCl or dilute HNO<sub>3</sub>. This is because oxygen produced from KMnO<sub>4</sub> + dil. H<sub>2</sub>SO<sub>4</sub> is used only for oxidising the reducing agent. Moreover, H<sub>2</sub>SO<sub>4</sub> does not give any oxygen of its own to oxidise the reducing agent.

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[\Theta] -$$

Reducing agent + [O] → Oxidised product

In case HCl is used, the oxygen produced from KMnO<sub>4</sub> is partly used upto oxidise HCl and Cl<sub>2</sub> is produced.

$$2KMnO_4 \longrightarrow K_2O + 2MnO + 5[O]$$

$$K_2O + 2HC1 \longrightarrow 2KC1 + H_2O$$

$$[MnO + 2HC1 \longrightarrow MnCl_2 + H_2O] \times 2$$

$$[2HCl + [O] \longrightarrow H_2O + Cl_2] \times 5$$

$$2KMnO_4 + 16HCl \longrightarrow 2KCl + 2MnCl_2 + 8H_2O + 5Cl_2$$

In case HNO<sub>3</sub> is used, it itself acts as an oxidising agent and partly oxidises the reducing agent.

**Example 17.** What is the equivalent mass of  $KMnO_4$  when it acts as an oxidising agent in acidic medium (molecular mass  $KMnO_4 = 158$ )?

#### Solution:

Oxidising action of KMnO<sub>4</sub> acidic medium is represented as:

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$
  
 $2 \times 158 \text{ g}$   $5 \times 16 = 80 \text{ g}$ 

Eq. mass of KMnO<sub>4</sub> = 
$$\frac{2 \times 158}{80} \times 8 = 31.6$$

or Eq. mass of KMnO<sub>4</sub>

 $= \frac{\text{Molecular mass}}{\text{Number of electrons gained per molecule}}$  $= \frac{158}{5} = 31.6$ 

or 
$$MnO_4^- \longrightarrow Mn^{2+}$$
  
Oxidation state  $+7 \longrightarrow +2$ 

Eq. mass of KMnO<sub>4</sub>

$$= \frac{\text{Molecular mass}}{\text{Change in oxidation state per molecule}}$$
$$= \frac{158}{5} = 31.6$$

**Example 18.** Explain the following giving suitable reason:

- (i) Yellow coloured aqueous solution of sodium chromate changes to orange red when CO<sub>2</sub> under pressure is passed.
- (ii) Green solution of potassium manganate,  $K_2MnO_4$ , turns purple when  $CO_2$  is circulated.

#### Solution:

(i) Yellow coloured aqueous solution of sodium chromate changes to orange red on passing CO<sub>2</sub> as H<sup>+</sup> ions are formed which are responsible for conversion of chromate into dichromate.

$$CO_2 + H_2O \Longrightarrow H^+ + HCO_3^-$$

$$2CrO_4^{2-} + 2H^+ \longrightarrow Cr_2O_7^{2-} + H_2O$$
Yellow Orange red

(ii) CO<sub>2</sub> gives H<sup>+</sup> ions which are responsible for conversion of manganate (green) to permanganate (purple).

$$CO_2 + H_2O \Longrightarrow H^+ + HCO_3^-$$
  
 $3MnO_4^{2-} + 4H^+ \longrightarrow 2MnO_4^- + MnO_2 + 2H_2O$   
Green Purple

**Example 19.** Assign reason for each of the following:

- (i)  $Ce^{3+}$  can be easily oxidised to  $Ce^{4+}$ .
- (ii)  $E^o$  for  $Mn^{3+}/Mn^{2+}$  couple is more positive than for  $Fe^{3+}/Fe^{2+}$  couple.
  - (iii) Lu(OH)3 is a weaker base than La(OH)3.

#### **Solution:**

(i)  $Ce^{3+}$  has the configuration  $4f^15d^06s^0$ . It can easily lose an electron to acquire more stable configuration  $(4f^05d^06s^0, i.e., configuration of an inert gas, xenon 2, 8, 18, 18, 8), i.e., <math>Ce^{3+}$  can be easily oxidised to  $Ce^{4+}$ .

$$Ce^{3+} \longrightarrow Ce^{4+} + e^{-1}$$

(ii)  $E^{\circ}$  for  $Mn^{3+}/Mn^{2+}$  couple is more positive than for  $Fe^{3+}/Fe^{2+}$  couple because  $Mn^{2+}$  state is more stable than  $Mn^{3+}$  state. Thus, the reduction is spontaneous.

$$Mn^{3+}(3d^4,4s^0) + e \longrightarrow Mn^{2+}(3d^5,4s^0)$$

For Fe<sup>3+</sup>/Fe<sup>2+</sup> couple, Fe<sup>3+</sup>( $3d^5$ , $4s^0$ ) is more stable than Fe<sup>2+</sup>( $3d^6$ , $4s^0$ ). Thus, the reduction is not spontaneous.

(iii) In the lanthanide series, the size of the  $M^{3+}$  ion decreases from  $La^{3+}$  to  $Lu^{3+}$ . Thus, the covalent nature of  $Lu(OH)_3$  increases (Fajan's rule). Hence,  $Lu(OH)_3$  is weaker than  $La(OH)_3$ .

**Example 20.** Transition metals of 3d-series do not react readily with dilute acids to liberate hydrogen although they have high negative reduction potential values. Explain.

#### Solution:

Most of the transition metals have the tendency to form a protective layer of their oxides on the surface. This oxide layer is somewhat inert and does not permit the metals to react with dilute acids to liberate hydrogen.

**Example 21.** The atomic radii of the elements in a transition series do not vary much while they do vary in the case of s and p-block elements. Explain.

#### **Solution:**

There are operating two effects namely nuclear charge effect and screening effect which oppose each other. Due to increase in nuclear charge from member to member in a transition series, the atomic radii tend to decrease. At the same time, the addition of extra electrons one by one to (n-1)d-orbitals provides the screening effect. As the number of d electrons increases, the screening effect increases and this tends to increase size. Due to these opposing tendencies, there is a very small change in the atomic radii in a transition series. In s and p-block elements, the extra electron is added to same s or p-subshell-which does not exert screening effect and hence, the atomic radii decreases considerably in a period due to increase in nuclear charge.

**Example 22.** The second and third members in each group of the transition elements have similar atomic radii. Explain.

#### Solution:

This is due to lanthanide contraction by the members of 4f-series which occupy a position between lanthanum (Z = 57, a first member of third transition series) and hafnium (Z = 72, second member of 3rd transition series).

The pairs of elements such as Zr-Hf, Nb-Ta, Mo-W, etc., possess nearly the same atomic radii and almost the same properties.

**Example 23.** (a) Chromium is a typical hard metal while mercury is a liquid. Explain.

- (b) The melting and boiling points of Zn, Cd and Hg are low. Why?
- (c) Though copper, silver and gold have completely filled sets of d-orbitals, yet they are considered as transition metals. Why?

#### **Solution:**

- (a) In chromium, the interatomic bonding is very strong due to presence of five unpaired electrons in 3d-subshell  $(3d^54s^1)$ . Therefore, it is a hard metal. In mercury, on the contrary, the 3d-subshell is filled to maximum capacity  $(5d^{10}6s^2)$ , i.e., these electrons are not available for interatomic bonding and thus, bonding is very weak in mercury. Therefore, mercury is a liquid at room temperature.
- (b) In Zn, Cd and Hg, the (n-1) *d*-orbitals are filled to their maximum capacity. These *d*-electrons do not take part in metallic bonding. Thus, metallic bonding is weak in Zn, Cd and Hg. That is why, they have low melting and boiling points.
- (c) Copper, silver and gold in their common oxidation states have partially filled (n-1) *d*-orbitals.

$$Cu^{2+}(3d^9)$$
;  $Ag^{2+}(4d^9)$ ;  $Au^{3+}(5d^8)$ 

**Example 24.** (a) Of the ions  $Ag^+$ ,  $Co^{2+}$  and  $Ti^{4+}$  which ones will be coloured in aqueous solution?

(b) If each one of the above ionic species is in turn placed in a magnetic field, how will it respond and why?

#### **Solution:**

- (a) The ionic species which possesses unpaired electron or electrons in (n-1) d-subshell will show colour. Of the ions  $Ag^+(4d^{10})$ ,  $Co^{2+}(3d^7$ —three unpaired electrons) and  $Ti^{4+}(3d^0)$ ,  $Co^{2+}$  will be coloured as it contains three unpaired electrons and  $Ag^+$  and  $Ti^{4+}$  will be colourless.
- (b) When placed in magnetic field, Co<sup>2+</sup> will be attracted because it is paramagnetic due to unpaired electrons. Ag<sup>+</sup> and Ti<sup>4+</sup> ions will be repelled by the magnetic field as they are diamagnetic due to presence of paired orbitals.

**Example 25.** Give examples and suggest reasons for the following features of the transition metal chemistry:

- (i) The lowest oxide of transition metal is basic, the highest is amphoteric/acidic.
- (ii) A transition metal exhibits highest oxidation state in oxides and fluorides.
- (iii) The highest oxidation state is exhibited in oxoanions of a metal.

#### **Solution:**

- (i) In case a metal forms a number of oxides, the acidic strength increases with the increase in oxidation state of the metal, *i.e.*, acidic strength increases with the increase in percentage of oxygen in the oxide. For example, MnO is a basic oxide while  $Mn_2O_7$  is an acidic oxide.
- (ii) A metal exhibits higher oxidation states in oxides and fluorides as oxygen and fluorine are highly electronegative elements and small in size, *i.e.*, act as strong oxidising agents. For example, chromium shows an oxidation state of +6 in  $CrF_6$  and osmium shows an oxidation state of +8 in  $OsO_4$ .
- (iii) This is also because of high electronegativity of oxygen. For example, chromium shows oxidation state of +6 in  ${\rm Cr_2O_7^{2-}}$  and manganese shows oxidation state of +7 in  ${\rm MnO_4^{-}}$ .

**Example 26.** (a) Actinide contraction is greater from element to element than lanthanide contraction. Why?

(b) The outer electronic configuration of two members of the lanthanide series are as follows:

$$4f^{1}5d^{1}6s^{2}$$
 and  $4f^{7}5d^{0}6s^{2}$ 

What are their atomic numbers? Predict the oxidation states exhibited by these elements in their compounds.

#### **Solution:**

- (a) This is due to poor shielding by 5f electrons in the actinides than that of 4f electrons in the lanthanides.
- (b) Complete E.C. of 1st element : [Xe]  $4f^15d^16s^2 = 58$ , *i.e.*, the element is cerium.

Complete E.C. of 2nd element : [Xe]  $4f^75d^06s^2 = 63$ , *i.e.*, the element is europium.

The expected oxidation states of 1st element = +3, and +4 and of 2nd element = +2, +3.

**Example 27.** Which is the most common oxidation state of lanthanides and how is it formed? Give its configuration. Solution:

The most common oxidation state of lanthanides is +3. This oxidation state of the lanthanide ions arises due to the loss of two 6s electrons and the lone 5d electron, if present from the atom of the elements. If no electron is present in the 5d orbital, than one of electrons from 4f shell is lost. The lanthanides in this state have the general configuration [Xe]  $4f^{1-14}$ .

# **SUMMARY AND IMPORTANT POINTS TO REMEMBER**

1. The elements belonging to groups 3 to 12 of the extended form of the periodic table are called d-block elements. They are present between s-block and p-block elements and belong to 4th, 5th, 6th and 7th periods of periodic table. They are also called transition elements (elements having incomplete (n-1)d-orbitals in their atoms or in their simple ions). Their general electronic configuration is:

$$(n-1)d^{1-10}ns^{0, 1 \text{ or } 2}$$

All transition elements are d-block elements but all d-block elements are not transition metals. For example, the elements of group 12, namely Zn, Cd, Hg and Uub, though belong to d-block but are not considered as transition metals because they contain completely filled (n-1)d-orbitals.

2. There are four transition series which involve the filling of (n-1)d-subshell. Each series consists ten elements. Each series starts from a member of third group and ends with a member of group 12.

First series (3*d*-series) Sc 
$$(3d^1,4s^2)$$
 — Zn  $(3d^{10},4s^2)$  (21) (30)  
Second series (4*d*-series) Y  $(4d^1,5s^2)$  — Cd  $(4d^{10},5s^2)$  (39) (48)  
Third series (5*d*-series) La  $(5d^1,6s^2)$  — Hg  $(5d^{10},6s^2)$  (57) (80)  
Fourth series (6*d*-series) Ac  $(6d^1,7s^2)$  — Uub  $(6d^{10},7s^2)$  (89) (112)

Certain elements show exceptional electronic configuration. In the first transition series Cr  $(3d^5,4s^1)$  and Cu  $(3d^{10},4s^1)$  have exceptional configuration.

The elements of first transition series are:
 Sc (21), Ti (22), V (23), Cr (24), Mn (25), Fe (26),
 Co (27), Ni (28), Cu (29) and Zn (30).

4. All the transition elements are metals. Iron is the most

abundant transition metal in the earth's crust. Technetium and all the members of fourth transition series are radioactive. Technetium is the first synthetic element. The elements after uranium are termed transuranic elements. These elements have been obtained artificially by nuclear transmutation. Transition elements have high density, hardness, high tensile strength, malleability, ductility, high thermal and electrical conductivity, high energy of atomisation, high melting and boiling points. Larger the number of unpaired electrons, stronger is the metallic bond and hence higher is the energy of atomisation and the melting point. That is why melting points increase in each series up to the fourth member, i.e., Cr, Mo and W (W—highest melting point 3410°C). However, the melting point of manganese in 3d-series is lower than its neighbours. This is due to stable configuration of manganese  $(3d^5, 4s^2)$ , i.e., metallic bonding is less. Among the transition metals, the lightest is Sc (density 3.0 g cm<sup>-3</sup>) and heaviest osmium (22.59 g cm<sup>-3</sup>) and iridium (22.61 g cm<sup>-3</sup>). Hg is known in liquid form under ordinary conditions.

į

- 5. Generally, the atomic radii of *d*-block elements in a series decrease with increase in atomic number but the decrease in atomic size is small after midway. In the first series, the atomic radii decrease upto Cr but after that it remains almost the same. The atomic radii of second and third transition series in the same vertical columns are almost the same. This is due to lanthanide contraction. The atomic radii of the pairs such as Zr-Hf, Nb-Ta, Mo-W, Ag-Au, etc., are almost same.
- 6. The ionisation energy gradually increases with increase in atomic number along a given transition series. The ionisation energies of 3d and 4d elements are irregular. The first ionisation energy of 5d elements is higher than 3d and 4d elements belonging to same group due to lanthanide contraction.
- 7. Transition metals show variable oxidation states (except first and last member of the series). The most common oxidation state of the first transition series is +2 except scandium. The maximum oxidation state increases with atomic number upto manganese in the first transition series. This is due to the involvement of 4s electrons and unpaired electrons of 3d-subshell. Manganese  $(3d^54s^2)$  shows maximum oxidation state of +7. Lower states are ionic while higher states are covalent.

The highest oxidation state shown by transition metal is +8 (by Ru and Os). Ions with the metal in a high oxidation state tend to be good oxidising agents ( $Cr_2O_7^{2-}$ ,  $MnO_4^-$ ) and ions with the metal in low oxidation state are good reducing agents ( $V^{2+}$ ,  $Cr^{2+}$ ).

- 8. Most of the transition metals and their compounds exhibit paramagnetism. Substances containing unpaired electrons are paramagnetic. Those containing no unpaired electron are diamagnetic. (Zn, Cd, Hg, Zn<sup>2+</sup>, Cd<sup>2+</sup>, Hg<sup>2+</sup>, Cu<sup>+</sup>, Sc<sup>3+</sup>, Ti<sup>4+</sup>, V<sup>5+</sup>, etc., are diamagnetic.) Magnetic moment is given as  $\mu = \sqrt{n(n+2)}$  B.M., where n = number of unpaired electrons. In the first transition series Cr has maximum paramagnetism and amongst ions Mn<sup>2+</sup> has maximum magnetic moment.
- 9. Most of the transition metal compounds (ionic as well as covalent) are coloured both in solid state and in aqueous solution. Colour is due to the presence of incomplete d-subshell, i.e., there is d-d transition. The ions with  $(n-1)d^0$  or  $(n-1)d^{10}$  configuration are colourless.  $Sc^{3+}$ ,  $Te^{4+}$ ,  $Cu^+$ ,  $Zn^{2+}$ , etc., are colourless because they have either  $3d^0$  or  $3d^{10}$  configuration. The following colours are observed for the common ions.

Ti<sup>3+</sup> V<sup>3+</sup> Mn<sup>3+</sup> Fe<sup>3+</sup> Fe<sup>2+</sup> Cu<sup>2+</sup> Co<sup>2+</sup> Ni<sup>2+</sup> Purple Green Violet Yellow Green Blue Pink Green

- 10. Transition metals have the tendency to form complex compounds, interstitial compounds and alloys. They and their compounds act as good catalysts.
- 11. Iron, cobalt and nickel are termed ferrous metals. Copper, silver and gold are called coinage metals. Zinc, cadmium and

mercury are called zinc metals. Principal ores of iron, copper, silver, zinc and mercury are:

Iron		Copper	,
Haematite	Fe <sub>2</sub> O <sub>3</sub>	Copper glance	Cu <sub>2</sub> S
Magnetite	Fe <sub>3</sub> O <sub>4</sub>	Copper pyrites or Chalcopyrites	CuFeS <sub>2</sub>
Limonite	Fe <sub>2</sub> O <sub>3</sub> ·3H <sub>2</sub> O	Malachite	Cu(OH)2·CuCO3
Siderite	FeCO <sub>3</sub>	Azurite	Cu(OH) <sub>2</sub> ·2CuCO <sub>3</sub>
Iron pyrite	FeS <sub>2</sub>	Cuprite	Cu <sub>2</sub> O
Silver		Zinc	•
Argentite or silver glance	Ag <sub>2</sub> S	Zinc blende	ZnS
Hom silver	AgCl	Calamine	$ZnCO_3$
	_	Zincite	ZnO
Mercury			
Cinnabar	HgS		

- 12. There are three commercial varieties of iron:
  - (i) Pig iron or cast iron: This is the most impure form. It contains about 2-5% carbon along with varying amounts of Mn, Si, S, P, etc. It is hard and brittle. It cannot be welded. It is used for casting purposes.
  - (ii) Wrought iron: It is the purest form. It contains not more than 0.5% impurities including carbon. It is soft, malleable and ductile. It can be welded. It can be easily magnetised.
  - (iii) Steel: The carbon content is between 0.5 to 1.5%. It contains small amounts of other metals such as Cr, Ni, Mn, etc.
- **13.** Cast iron or pig iron is usually extracted from the oxide ore. It involves the following steps:
  - (i) Concentration by gravity process; (ii) Calcination in reverberatory furnace; (iii) Smelting in blast furnace. The calcined ore is mixed with coke and limestone and smelted in the blast furnace where CO produced as a result of combustion of coke reduces  $Fe_2O_3$  into Fe.

$$\begin{split} \text{Fe}_2\text{O}_3 + \text{CO} &\longrightarrow 2\text{FeO} + \text{CO}_2 \\ \text{FeO} + \text{CO} &\longrightarrow \text{Fe} + \text{CO}_2 \\ \text{CaCO}_3 &\longrightarrow \text{CaO} + \text{CO}_2 \\ \text{CaO} + \text{SiO}_2 &\longrightarrow \text{CaSiO}_3 \\ \text{Slag} \end{split}$$

- 14. Steel is manufactured from cast iron or pig iron by Bessemer process, open hearth process or electric process. Spiegeleisen—an alloy of Fe, Mn and C is added during manufacture. Steel is given heat treatment in order to impart special properties.
  - (i) Annealing: It involves heating of steel much below red heat and then cooled slowly. It makes steel soft.
  - (ii) Quenching: It involves heating of steel to red heat followed by sudden cooling by plunging into water or oil. It makes steel hard and brittle.
  - (iii) Tempering: It involves heating of steel which has already been quenched to a temperature 230-300°C and then allowed to cool slowly. It makes steel hard but brittleness disappears.

Some special steels are:

(i) Stainless steel (Fe, Cr, Ni, C). It is resistant to corrosion

- and is used for making utensils, cutlery and ornamental pieces.
- (ii) Invar (Fe, Ni). It has small coefficient of expansion and is used for making metre rods, pendulum rods and springs for watches.
- (iii) Manganese steel (Fe, Mn, C). It is very hard. It is used for making rock drills, almirah, etc.
- (iv) Tungsten steel (Fe, W, C). It is hard and is used for making high speed cutting tools.
- (v) Alnico (Fe, Al, Ni, Co). It is highly magnetic and is used for making permanent magnets.
- 15. Copper is extracted from chalcopyrites. The ore is concentrated by froth floatation process, roasted in reverberatory furnace and then smelted in a blast furnace when molten 'matte' containing Cu<sub>2</sub>S + FeS (little) is obtained. It is transferred to Bessemer converter and heated with a blast of hot air, when blister copper is obtained.

$$Cu_2S + 2Cu_2O \longrightarrow 6Cu + SO_2$$

Blister copper contains 96–98% copper along with small amounts of Ag, Au, Ni, Zn, Pb, Sn, etc. It is further purified by poling process and electrolytic process.

Copper is used for making electrical wires, electroplating, coins and many useful alloys such as brass (Cu and Zn), bronze (Cu and Sn), german silver (Cu, Zn and Ni), constantan (Cu and Ni), rolled gold (Cu and Al), etc.

16. Silver is extracted from argentite. It is concentrated by froth floatation process. The concentrated ore is ground to fine powder. This is treated with dilute solution (0.4 to 0.6%) of sodium cyanide and a current of air is circulated. Silver present in the ore dissolves.

$$Ag_2S + 4NaCN \Longrightarrow 2NaAg(CN)_2 + Na_2S$$

$$4Na_2S + 5O_2 + 2H_2O \longrightarrow 2Na_2SO_4 + 4NaOH + 2S$$

Silver is precipitated from the solution by addition of zinc powder.

$$2NaAg(CN)_2 + Zn \longrightarrow Na_2Zn(CN)_4 + 2Ag$$

The precipitated silver is dried and fused with KNO<sub>3</sub> in a crucible. Liquid silver on cooling appears as a compact mass. The main impurities are lead, copper and gold. These are removed by cupellation and electrolytic processes. Silver is used, for making coins, ornaments, silverware and in electroplating. Silver salts are used in photography, silvering of mirrors and for making marking inks and medicine.

17. Zinc is extracted either from zinc blende or calamine. When zinc blende is used the powdered ore is concentrated by froth floatation process. In case of calamine, the ore is concentrated by gravity process. The concentrated ore is heated in excess of oxygen at about 900°C. Zinc sulphide is oxidised to zinc oxide.

$$2ZnS + 3O_2 \longrightarrow 2ZnO + 2SO_2$$

Reduction of oxide is done by carbon.

$$ZnO + C \longrightarrow Zn + CO$$
,  $ZnO + CO \longrightarrow Zn + CO_2$ 

Zinc is also recovered by electrolytic process. The roasted ore is dissolved in dilute sulphuric acid. The solution is freed from iron, aluminium and silica, etc. The solution is then electrolysed by using a sheet of pure Al as cathode and pure lead plate as anode. The zinc is removed from cathode by melting. The zinc obtained is 99.95% pure.

The impure zinc obtained by reduction process is known as **spelter.** Granulated zinc is made by melting the metal in a crucible and pouring the drops in water. Zinc dust is made by melting zinc and then atomising it with a blast of air. Zinc is used in the manufacture of various important alloys such as brass, german silver, etc. The most important use of zinc is for galvanising iron. It is also used for extraction of Ag and Au, as a reducing agent in laboratory and zinc rods in making electric batteries.

**18.** Mercury is extracted from cinnabar. It is concentrated by froth floatation process. The concentrated ore is then roasted in excess of air when mercury is obtained.

$$HgS + O_2 \longrightarrow Hg + SO_2$$

The mercury is refined by first passing it through dilute HNO<sub>3</sub> and then distilled. Mercury forms alloys (amalgams) with all metals except Fe and Pt. Hg is used in thermometers, manometers and barometers.

(i) Copper sulphate (CuSO<sub>4</sub>·5H<sub>2</sub>O) is called blue vitriol. It
is prepared by dissolving cupric oxide, cupric hydroxide
or copper carbonate in dilute H<sub>2</sub>SO<sub>4</sub>.

In  $CuSO_4.5H_2O$ , the four water molecules are coordinated to control  $Cu^{2+}$  ion while fifth one is attached to  $SO_4^{2-}$  ion by H-bonding.

With KI, it gives white Cu<sub>2</sub>I<sub>2</sub> and free iodine.

$$[2CuSO_4 + 4KI \longrightarrow Cu_2I_2 + 2K_2SO_4 + I_2]$$

With excess of NH<sub>4</sub>OH, CuSO<sub>4</sub> gives deep blue solution due to complex formation.

$$CuSO_4 + 4NH_4OH \longrightarrow Cu(NH_3)_4SO_4 + 4H_2O$$

A mixture of CuSO<sub>4</sub> and Ca(OH)<sub>2</sub> is used as a fungicide under the name of **Bordeaux mixture**.

- (ii) Silver nitrate (AgNO<sub>3</sub>) is called **lunar caustic.** It is obtained by dissolving silver in dilute nitric acid. On coming in contact with organic matter like skin or cloth it is reduced to silver giving a black stain. It gives different coloured precipitates with acidic radicals such as Cl<sup>-</sup>, Br<sup>-</sup>, I<sup>-</sup>, CrO<sub>4</sub><sup>2</sup>, S<sup>2</sup>-, S<sub>2</sub>O<sub>3</sub><sup>2</sup>-, PO<sub>4</sub><sup>3</sup>-, etc.
  - It is used for making silver halides, as a laboratory reagent, silvering mirrors and for making marking ink.
- (iii) Out of AgCl, AgBr and AgI, AgBr is most sensitive to light and is used in photography.
- (iv) Hg forms two chlorides. Mercury (I) chloride, i.e., mercurous chloride (Hg<sub>2</sub>Cl<sub>2</sub>) is also called calomel. It is nonpoisonous. It turns black when treated with ammonia due to deposition of Hg. The oxidation state of Hg is +1 but valency is 2, e.g., in Hg<sub>2</sub><sup>2+</sup> (—Hg—Hg—) two atoms are joined together by a covalent bond. It is used for making calomel electrode and as a purgative in medicine.

Mercury(II) chloride, *i.e.*, mercuric chloride (HgCl<sub>2</sub>) is also called **corrosive sublimate.** It is highly poisonous (corrosive) and undergoes sublimation. Its antidote is

the white of an egg. It is less soluble in cold water but soluble in hot water and in organic solvents. It is a covalent compound. It is reduced by SnCl<sub>2</sub> and copper. Its very dilute solution (0.1%) is used as antiseptic.

- (v) HgI<sub>2</sub> dissolves in excess of KI to form K<sub>2</sub>HgI<sub>4</sub>. An alkaline solution of K<sub>2</sub>HgI<sub>4</sub> is called Nessler's reagent. It is used for the test of NH<sub>3</sub> or NH<sub>4</sub><sup>+</sup> ion.
- (vi) K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is prepared from the chromite ore (FeO·Cr<sub>2</sub>O<sub>3</sub>). The finely powdered ore is mixed with sodium carbonate and the mixture is fused in reverberatory furnace in excess of air. The roasted mass is extracted with water and the solution is treated with conc. H<sub>2</sub>SO<sub>4</sub>·Na<sub>2</sub>SO<sub>4</sub>·10H<sub>2</sub>O being less soluble crystallises our and is filtered. Hot solution of Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is treated with calculated amount of KCl when K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> crystals are obtained.

$$4\text{FeO}\cdot\text{Cr}_2\text{O}_3 + 8\text{Na}_2\text{CO}_3 + 7\text{O}_2 \longrightarrow$$

$$8Na_2CrO_4 + 2Fe_2O_3 + 8CO_2$$
Soluble Insoluble ==
$$2Na_2CrO_4 + H_2SO_4 \longrightarrow Na_2Cr_2O_7 + Na_2SO_4 + H_2O$$

$$Na_2Cr_2O_7 + 2KCl \longrightarrow K_2Cr_2O_7 + 2NaCl$$

It is an orange crystalline compound. It decomposes on heating to give  $K_2CrO_4$ ,  $Cr_2O_3$  and  $O_2$ . Its acidic solution contains dichromate ions while alkaline solution contains chromate ions. It is a strong oxidising agent. Acidified solution is used as a primary standard in volumetric analysis for the estimation of reducing agents such as ferrous sulphate, oxalic acid, etc. On heating with a chloride (NaCl) and conc.  $H_2SO_4$ , red vapours of  $CrO_2Cl_2$  (chromyl chloride) are evolved. Its equivalent mass in acidic medium is mol. mass/6 = 49.

finely powdered ore is fused with KOH or K<sub>2</sub>CO<sub>3</sub> in presence of air or oxidising agent when K<sub>2</sub>MnO<sub>4</sub> (manganate) is formed. It is oxidised chemically by using H<sub>2</sub>SO<sub>4</sub>, CO<sub>2</sub> or Cl<sub>2</sub> or electrolytically.

It is a deep purple crystalline compound, moderately soluble in water. It decomposes when heated giving O<sub>2</sub>. It acts as a strong oxidising agent in neutral, alkaline and acidic media. The acidified KMnO<sub>4</sub> (dil. H<sub>2</sub>SO<sub>4</sub>) is used as a volumetric reagent. It is not a primary standard, *i.e.*, it is first standardised and then used. Its equivalent mass in acidic medium is mol. mass/5 = 31.6. Alkaline KMnO<sub>4</sub> solution is called **Baeyer's reagent** used in organic analysis. It has tetrahedral structure.

(vii) KMnO<sub>4</sub> is prepared from pyrolusite ore (MnO<sub>2</sub>). The

**20.** The *f*-block elements (inner transition elements) are placed outside the periodic table. Their general configuration is :

$$(n-2)f^{1-14}(n-1)d^{0,1}ns^2$$

There are two series:

- (a) **4f-series:** 4f-orbitals are gradually filled up. These are 14 elements from Ce (58) to Lu(71) and are called lanthanides as these show similarities with La(57).
- **(b) 5***f***-series:** 5*f*-orbitals are gradually filled up. These are also 14 elements from Th (90) to Lr (103) and are called **actinides** as these show similarities with actinium,

Ac (89). These are radioactive elements. Most of these are man-made.

- 21. There is gradual decrease in the atomic and ionic sizes of these metals along the series. These are called lanthanide contraction and actinide contractions. Lanthanide contraction is responsible for various changes in chemical properties of the elements succeeding them.
- 22. All the lanthanides are rather soft white metals. They react easily with water to give solutions giving +3 ions. The principal oxidation state is +3 although +4, +2 oxidation states are also exhibited. Those having +2 (i.e., Sm<sup>2+</sup>, Eu<sup>2+</sup> and Yb<sup>2+</sup>) change to +3, and act as reducing agents. Those having +4 tend to change to +3 and act as oxidising agents. The maximum oxidation state shown by actinides is +7. U, Np and Pu show oxidation state of +6. However, all the actinides also show +3 oxidation state.
- 23. Paramagnetism is shown by the positive ions of lanthanides except  $La^{3+}(4f^0)$  and  $Lu^{3+}(4f^{14})$ . Most of the trivalent lanthanide ions are coloured. This is due to f-f transition. Actinide cations are also generally coloured. The cations having  $5f^0$  or  $5f^7$  or  $5f^{14}$  configuration are colourless.
- 24. La(OH)<sub>3</sub> is most basic while Lu(OH)<sub>3</sub> is least basic.
- 25. The inertness exhibited by certain metals under conditions when chemical activity is to be expected is called passivity. Iron is rendered passive by oxidising agents like conc. HNO<sub>3</sub>, conc. H<sub>2</sub>SO<sub>4</sub>, KMnO<sub>4</sub>, chromic acid, etc. The passivity of iron is believed to be due to formation of an extremely thin film of oxide on the surface. Passive iron can be made active by scratching or removing oxide film chemically.
- 26. There are many compounds of transition metals which are used as catalysts. For example:

Adam's catalyst

- Pt/PtO

Brown's catalyst

Nickel boride

Zeigler-Natta catalyst

- TiCl<sub>4</sub> + (C<sub>2</sub>H<sub>5</sub>)<sub>3</sub>Al

Wilkinson's catalyst

— [Ph<sub>3</sub>P]RhCl

27. There are many compounds of transition elements which are used as reagents in laboratory or industry. For example,

Baeyer's reagent

Dilute alkaline soln. of KMnO<sub>4</sub>

Tollen's reagent

AgNO<sub>3</sub> soln. + NaOH soln.

+ NH₄OH

Schweitzer's reagent ---

[Cu(NH<sub>3</sub>)<sub>4</sub>]SO<sub>4</sub>

Nessler's reagent

Alk. soln. of K2HgI4

Benedict's solution

CuSO<sub>4</sub> soln. + sod. citrate

+ Na<sub>2</sub>CO<sub>3</sub>

Fehling's solution

CuSO<sub>4</sub> soln. + sodium potassium

tartrate

Fenton's reagent

 $FeSO_4 + H_2O_2$ 

Etard's reagent

CrO<sub>2</sub>Cl<sub>2</sub>

Bordeaux mixture

— CuSO<sub>4</sub> soln. + lime

Lucas reagent

— Conc. HCl + anhydrous ZnCl<sub>2</sub>

Barfoed's reagent — Cu(CH<sub>3</sub>COO)<sub>2</sub>+CH<sub>3</sub>COOH

28. Some of the substances having compounds of transition metals are given special names.

Paris green — Cu(CH<sub>3</sub>COO)<sub>2</sub>·3Cu(AsO<sub>2</sub>)<sub>2</sub>

Rinnmann's green ZnO·CoO or CoZnO<sub>2</sub> (Cobalt zincate)

Verdigris — Cu(CH<sub>3</sub>COO)<sub>2</sub>·Cu(OH)<sub>2</sub>

Fulminating gold

Calomel — Hg<sub>2</sub>Cl<sub>2</sub> Corrosive sublimate — HgCl<sub>2</sub> Lunar caustic — AgNO₃ Philospher's wool - ZnO

or pompholyx

Blue vitriol — CuSO<sub>4</sub>·5H<sub>2</sub>O (Nila Thotha) Green vitriol — FeSO<sub>4</sub>·7H<sub>2</sub>O (Hara kasis)

Horn silver - AgCl

Mohr's salt — FeSO<sub>4</sub>·(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>·6H<sub>2</sub>O

Prussian blue - Fe<sub>4</sub>[Fe(CN)<sub>6</sub>]<sub>3</sub> White vitriol — ZnSO₄·7H₂O

Vermilion --- HgS

Purple of cassius -- Colloidal gold solution

Fool's gold — FeS<sub>2</sub> or CuFeS<sub>2</sub> Titanox - TiO<sub>2</sub> + BaSO<sub>4</sub> --- ZnS + BaSO<sub>4</sub> Lithophone

Vaska's compound — Trans IrCl (CO) (PPh<sub>3</sub>)<sub>2</sub>

- 29. Finely reduced form of platinum in the form of velvety black powder is called platinum black.
- 30. Titanium has been called 'The wonder metal' because of its useful properties. It is very hard, very light and has high melting point.
- 31. Mischmetal, an alloy which contains rare earth elements (94– 95%), iron (5%) and traces of sulphur, carbon, silicon, calcium and aluminium. It is pyrophoric and is used in cigarette and gas lighters, tracer bullets and shells. The main rare earth elements present in this alloy are cerium (≈ 40%), lanthanum and neodymium ( $\approx 44\%$ ).

An alloy containing magnesium and about 3% mischmetal is used in jet engine parts.

32. Technitium (Z = 43) does not occur in nature. It is a synthetic element. It was discovered, in 1937, by Segre.

Promethium (Z = 61) does not occur in nature also.

- 33. (a) Rolled gold is an alloy of Cu (95%) and Al (5%) and is used for artificial jewellery.
  - (b) Impure zinc is called spelter.
  - (c) German silver does not contain silver. It is an alloy of Cu (56%), Zn (24%) and Ni (20%).
  - (d) Iron does not form amalgam with mercury.
  - (e) Sterling silver is an alloy of Ag (80%) and Cu (20%).
  - **Permalloy** (Fe 21%, Ni 78% + C) is strongly magnetised by electric current but loses magnetism when electric current is cut off.
  - (g) Alnico (Fe = 60%, Al = 12%, Ni = 20% and Co = 8%) is highly magnetic and is used for permanent magnets.

# -\*••- PRACTICE PROBLEMS -•••-

### Subjective Type Questions

- 1. How do the following properties vary in the transition elements?
  - (a) Atomic size
  - (b) Stability of various oxidation states
  - (c) Ionisation energy
- 2. Explain the following:
  - (a) Mercury is a liquid.
  - (b) Why CuSO<sub>4</sub> is blue while ZnSO<sub>4</sub> is white.
  - (c) Why zinc and cadmium are soft metals.
- 3. (a) Which one out of the each of following pairs is more stable?
  - (i)  $Cr^{2+}$ ,  $Cr^{3+}$  (ii)  $Fe^{3+}$ ,  $Fe^{2+}$  (iii)  $Mn^{2+}$ ,  $MnO_4^-$
  - (b) Which one of the following-tend to be an oxidising or reducing agent?
    - (i)  $Cr^{2+}$  (ii)  $Cr_2O_7^{2-}$  (iii)  $MnO_4^-$  (iv)  $Ti^{2+}$
- 4. Predict the spin only megnetic moment for:
  - (a)  $Fe^{2+}$  (b)  $Mn^{2+}$  (c)  $Cr^{6+}$  (d)  $Cu^{+}$
- 5. Answer the following:
  - Name the lightest and heaviest elements in terms of density among the transition elements.
  - (ii) Name the transition element which does not show variable oxidation states.
  - (iii) Name the member of lanthanide series which is well known to exhibit +4 oxidation state.
  - (iv) The +3 oxidation state of lanthanum (Z = 57), gadolinium (Z = 64) and lutetium (Z = 71) are especially stable.
  - (v) Why lanthanides are paramagnetic in nature?
- 6. What happens when?
  - (i) Hot and concentrated nitric acid reacts with copper.
  - (ii) Copper sulphate reacts with potassium iodide.
  - (iii) Ammonia solution is added to copper sulphate solution.
    [M.L.N.R. 1991]
  - (iv) Cupric chloride is heated with concentrated HCl and copper turnings.
  - (v) Copper is heated with concentrated H<sub>2</sub>SO<sub>4</sub>.
  - (vi) Potassium iodide is added first and then sodium thiosulphate to a solution of copper sulphate.
  - (vii) Sulphur dioxide is circulated through a solution of copper sulphate containing sodium chloride.
  - (viii) Silver chloride is treated with excess of ammonium hydroxide.
  - (ix) Gold is dissolved in aqua-regia.
  - (x) Sodium thiosulphate solution is added to silver bromide.
- 7. What happens when?
  - (i) Excess of caustic soda solution is added slowly to zinc chloride solution.
  - (ii) Excess of ammonium hydroxide solution is added to zinc chloride solution.
  - (iii) Mercuric chloride is treated with NH4OH.

- (iv) Mercurous chloride is treated with NH<sub>4</sub>OH.
- (v) Potassium iodide is added in excess to the solution of ferric sulphate.
- (vi) Potassium permanganate solution is added to ferrous sulphate solution in presence of sulphuric acid.
- (vii) Potassium nitrite reacts with cobalt chloride in presence of acetic acid.
- (viii) H<sub>2</sub>S is circulated through acidic solution of ferric chloride.
- 8. What happens when the following chemical compounds are heated?
  - (i) Silver nitrate
- (ii) Blue vitriol
- (iii) White vitriol
- (iv) Green vitriol
- (v) Hydrated zinc chloride
- (vi) Mercurous chloride
- (vii) Zinc carbonate (ix) Zinc nitrate
- (viii) Mercuric nitrate(x) Mercuric oxide
- (ix) Zinc initale
- (xi) Hydrated ferric chloride (xii) Cupric nitrate
- 9. Complete and balance the following equations:
  - (i)  $CuSO_4 + Na_2CO_3 + H_2O \longrightarrow ... + Na_2SO_4 + ...$ 
    - [I.I.T. 1992]
  - (ii)  $CuSO_4 + NH_4OH \longrightarrow ... + ...$
  - (iii) AgBr + Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>  $\longrightarrow \dots + \dots$
- [L.I.T. 1993]

- (iv)  $CuSO_4 + KI \longrightarrow ...$
- (v)  $CuSO_4 + KCN \longrightarrow ...$
- (vi)  $Ag^+ + AsH_3 + \dots \rightarrow H_3AsO_3 + H^+ + \dots$
- (vii)  $Ag + CN^- + O_2 + \dots \longrightarrow OH^- + \dots$  [Roorkee 1996]
- (viii)  $HgCl_2 + SnCl_2 \longrightarrow ...$
- (ix)  $CdSO_4 + NH_4OH \longrightarrow ...$
- (x)  $HgCl_2 + SO_2 + ... \longrightarrow ...$
- (xi)  $[Fe(H_2O)_6]^{2+} + NO_3^- + H^+ \longrightarrow \dots + [Fe(H_2O)_6]^{3+} + H_2O$  $[Fe(H_2O)_6]^{2+} + \dots \longrightarrow \dots + H_2O$  [L.T. 1993]
- (xii)  $FeCl_3 + H_2S \longrightarrow ...$
- (xiii)  $MnO_4^- + Fe^{2+} \longrightarrow Mn^{2+} + Fe^{3+} + H_2O$ (Acidic medium) [Roorkee 1996]
- (xiv)  $Fe^{2+} + NO_3^- + H^+ \longrightarrow Fe^{3+} + ... + H_2O$  [Roorkee 1996]
- (xv)  $FeCl_3 + KI \longrightarrow ...$
- (xvi)  $Ag_2S + 2CuCl_2 + 2Hg \longrightarrow ... + ... + S + 2Ag$ [Roorkee 1998]
- (xvii) Au + HCl + HNO<sub>3</sub>  $\longrightarrow$  ... + ... + H<sub>2</sub>O [Roorkee 1999]
- (xviii)  $Cu(OH)_2 + NH_4NO_3 + NH_4OH \longrightarrow ... + H_2O$

[Roorkee 1999]

- 10. How will you obtain the following?
  - (i) Cuprous chloride from copper sulphate.
  - (ii) Silver nitrate from silver.
  - (iii) Silver from silver nitrate.
  - (iv) Mercury from corrosive sublimate.
  - (v) Zinc chloride from zinc sulphate.
  - (vi) Anhydrous ferric chloride from iron.
  - (vii) Ferric chloride from ferrous sulphate.

- 11. Give the balanced equations for the:
  - (i) Reaction of argentite with KCN. Name the products in solution. [L.I.T. 1996]
  - (ii) Recovery of silver from silver coin.
  - (iii) Extraction of copper from copper pyrites by self reduction. [I.I.T. 1990]
  - (iv) Extraction of zinc from zinc blende.
  - (v) Reactions occurring in blast furnace in the extraction of iron.
- 12. Name two principal ores of each of the following metals:
  - (i) Copper (ii) Silver (iii) Zinc (iv) Mercury (v) Iron
- 13. Give the constituents of following alloys:
  - (i) Brass (ii) German silver (iii) Bronze (iv) Rolled gold
  - (v) Constantan (vi) Invar (vii) Stainless steel (viii) Gun metal

#### 14. Answer the following:

- (i) What are d-block elements?
- (ii) What is the general electronic configuration of *d*-block elements?
- (iii) Name three characteristic properties of d-block elements.
- (iv) Name the first and last element of 3d-series.
- (v) Name the two elements of 3*d*-series which show anomalous electronic configuration.
- (vi) Transition elements form alloys easily. What is the reason?
- (vii) Which ions of first transition series show highest paramagnetism?
- (viii) Why the compounds of transition elements are coloured?
- (ix) Why Fe<sup>3+</sup> compounds are more stable?
- (x) Why most of the compounds of transition elements are paramagnetic?
- (xi) What is the maximum oxidation state of manganese?
- (xii) What is the maximum oxidation state of chromium?
- 15. Write short notes on the following:
  - (i) Refining of blister copper (ii) Silver plating
  - (iii) Silvering of mirrors
- (iv) Poling process
- (v) Cupellation process
- (vi) Galvanisation
- (vii) Lithopone
- (viii) Nessler's reagent
- (ix) Passivity
- (x) Heat treatment of steel
- (xi) Corrosion of iron
- (xii) Types of iron
- 16. Explain the following giving proper reason.
  - Anhydrous ferric chloride cannot be obtained by heating hydrated ferric chloride.

[Hint: On heating, it reacts with water of crystallisation and converted into  $Fe_2O_3$  with evolution of HCl.

$$2[FeCl_3·6H_2O] \xrightarrow{Heat} Fe_2O_3 + 6HCl + 9H_2O]$$

(ii) ZnO is used as a white paint inspite of the fact that it has less covering power than white lead.

[Hint: ZnO is not blackened in atmosphere of hydrogen sulphide. It can be used both as oil and water paint. It is non-poisonous in nature.]

(iii) CuSO<sub>4</sub> is paramagnetic while ZnSO<sub>4</sub> is diamagnetic.

[Hint:  $Cu^{2+}$  ion has  $3d^9$  configuration, *i.e.*, one unpaired orbital while  $Zn^{2+}$  ion has  $3d^{10}$  configuration, *i.e.*, all orbitals doubly occupied.]

(iv) Hydrated zinc chloride cannot be dehydrated on heating?
 [Hint: On heating it reacts with water of crystallisation and forms zinc oxychloride.

$$2ZnCl_2 \cdot 2H_2O \longrightarrow Zn_2OCl_2 + 2HCl + 3H_2O$$

(v) Zinc is used in the galvanisation of iron.

[Hint: Zinc coating protects the iron from corrosion as zinc is not affected by oxygen and water.]

(vi) Poling process is used in the purification of copper.

[Hint: The oxide of copper which remains in the copper (blister) is reduced by introducing poles of green wood. The gas (hydrocarbons, CO, H<sub>2</sub>, etc.) bubbles originating from the wood act as reducing agents. The mass is stirred with these green poles vigorously.]

(vii) A solution of ferric chloride gives a brown precipitate on standing.

[Hint: Hydrolysis of ferric chloride occurs giving finally brown precipitate.

FeCl<sub>3</sub> + 
$$3H_2O \rightleftharpoons Fe(OH)_3 + 3HCl$$

$$2Fe(OH)_3 \longrightarrow Fe_2O_3 + 3H_2O]$$
Brown

(viii) Transition metals and their compounds act as catalysts.
 [Hint: Because of the availability of d-orbitals they can easily form intermediate products which are activated. The

sizes of transition metal atoms and ions are also favourable for transitory complex formation with the reactants.]

(ix) In moist air copper corrodes to produce a green layer on the surface. [I.I.T. 1998]

[Hint: Copper in presence of moisture oxygen and carbon dioxide of atmosphere is converted into basic carbonate which is deposited as green layer on surface.

$$2Cu + CO_2 + H_2O + O_2 \longrightarrow Cu(OH)_2CuCO_3$$

- 17. Due to lanthanide contraction which properties are expected to be similar in the same vertical columns of the second and third row transition elements besides atomic radii?
- **18.** Calculate magnetic moments of  $M^{2+}$  ions of Ti(Z=22), Cr(Z=24), Mn(Z=25) and Cu(Z=29) and arrange them in increasing order.
- 19. Explain by giving suitable reason.
  - (i) Yellow coloured aqueous solution of sodium chromate changes to orange-red when CO<sub>2</sub> under pressure is passed.

[Hint: CO<sub>2</sub> gives H<sup>+</sup> ions which are responsible for the conversion of chromate into dichromate (orange-red).

$$CO_2+H_2O \rightleftharpoons HCO_3^2+H^+$$
  
 $2CrO_4^{2^-} + 2H^+ \longrightarrow Cr_2O_7^{2^-}+H_2O]$ 

(ii) CO<sub>2</sub> is evolved when NaHCO<sub>3</sub> is added to FeCl<sub>3</sub> solution.

[Hint: FeCl<sub>3</sub> undergoes hydrolysis giving HCl which reacts with NaHCO<sub>3</sub> to form CO<sub>2</sub>.

$$\begin{aligned} & \text{FeCl}_3 + 3\text{H}_2\text{O} \longrightarrow \text{Fe(OH)}_3 + 3\text{HCl} \\ & \text{NaHCO}_3 + \text{HCl} \longrightarrow \text{NaCl} + \text{H}_2\text{O} + \text{CO}_2 ] \end{aligned}$$

(iii) Green solution of potassium manganate, K<sub>2</sub>MnO<sub>4</sub>, turns purple when CO<sub>2</sub> is circulated.

[Hint:  $CO_2$  gives  $H^+$  ions which are responsible for conversion of  $MnO_4^{2-}$  into  $MnO_4^{-}$  (purple).

$$\begin{array}{c} CO_2\text{+}H_2O \iff H^+\text{+}HCO_3^-\\ 3MnO_4^{2^-} + 4H^+ & \longrightarrow 2MnO_4^- + MnO_2 + 2H_2O]\\ \text{Green} \end{array}$$

(iv)  $Hg^{2+}$  and  $Hg_2^{2+}$  salts are colourless.

[Hint:  $Hg^{2+}$  and  $Hg_2^{2+}$  salts have  $5d^{10}$  configuration, i.e., there is no d-d transition, hence colourless.]

(v) Cu2+ salts are paramagnetic while Cu+ salts are diamagnetic in nature.

[Hint:  $Cu^{2+}$  configuration is  $3d^{9}$ (one orbital is singly occupied)—Paramagnetic;  $Cu^{+}$  configuration is  $3d^{10}$ (all orbitals are doubly occupied)—Diamagnetic.]

#### 20. Explain:

(a) Why is K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> generally preferred to Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in volumetric analysis?

[Hint: K2Cr2O7 is not hygroscopic and can be used as primary standard.]

(b) Which divalent metal ion has maximum paramagnetic character among the first transition metals? Why?

[Hint: Mn<sup>2+</sup>. It has maximum number of unpaired electrons.]

(c) HgCl<sub>2</sub> and SnCl<sub>2</sub> cannot exist together in an aqueous solution. Why?

[Hint: SnCl2 is a strong reducing agent. It reduces HgCl2 to

$$2HgCl_2 + SnCl_2 \longrightarrow Hg_2Cl_2 + SnCl_4$$
  
 $Hg_2Cl_2 + SnCl_2 \longrightarrow 2Hg + SnCl_4$ 

(d) Why does AgNO<sub>3</sub> produce a black stain on the skin? [Hint: In the presence of organic matter and light, AgNO3 decomposes to give a black stain of metallic silver.

$$2AgNO_3 \longrightarrow 2Ag + 2NO_2 + O_2$$

(e) How the colour of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution does depend on pH of the solution?

[Hint: In the solution, the following equilibria exists:

$$Cr_2O_7^{2-} + H_2O \rightleftharpoons 2CrO_4^{2-} + 2H^+$$

In acidic medium (pH < 7), it exists as  $Cr_2O_7^{2-}$  ions and has orange colour while in basic medium (pH>7), it exists as CrO<sub>4</sub> ions and has yellow colour.]

## tuswers

#### **Answers:** Subjective Type Questions

- 1. See the trends in properties.
- (a) No metallic bond formation is present.
  - (b)  $Cu^{2+}$  in  $CuSO_4$  has [Ar]  $3d^94s^0$  configuration. It can undergo d-d transition. It absorbs red region of the visible light and hence CuSO<sub>4</sub> appears blue as blue is complimentary colour of red. In  $ZnSO_4$ ,  $Zn^{2+}$  has  $3d^{10}4s^0$  configuration. It cannot undergo d-d transition, hence it appears colourless.
  - (c) Zn and Cd have no unpaired electron and thus there is no metallic bonding. Hence, they are soft in nature.
- (a) (i)  $Cr^{3+}$  (ii)  $Fe^{3+}$  (iii)  $Mn^{2+}$ 
  - (b) (i) reducing agent (ii) oxidising agent (iii) oxidising agent (iv) reducing agent.

<b>.</b>	Ion	Electronic Configuration	No. of unpaired electrons	Magnetic moment
	(a) Fe <sup>2+</sup>	[Ar] $3d^64s^0$	4	4.90 BM
	(b) $Mn^{2+}$		. 5	5.96 BM

### QUESTIONS BASED ON THE PROPERTIES

- 1. An unknown inorganic compound (A) gave the following reactions:
  - (a) The compound (A) on heating gave a residue and a gaseous mixture of NO<sub>2</sub> and oxygen.
  - (b) The compound (A) with tap water gave a turbidity which did not dissolve in conc. HNO<sub>3</sub>.
  - (c) The aqueous solution of (A) gave a white precipitate with sodium chloride solution. The precipitate dissolves in excess of ammonium hydroxide.

Identify the compound (A) and give the balanced equations. [Ans. The compound (A) is AgNO<sub>3</sub>

(a) 
$$2AgNO_3 \longrightarrow 2Ag + 2NO_2 + O_2$$
  
(b)  $AgNO_3 + Cl \longrightarrow AgCl + NO_3$   
(c)  $AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$   
 $AgCl + 2NH_4OH \longrightarrow Ag(NH_3)_2Cl + 2H_2O]$ 

2. A black coloured compound (A) on reaction with dilute H<sub>2</sub>SO<sub>4</sub> gives a gas (B) which on passing in a solution of acid (C) gives a white turbidity (D). Gas (B) when passed in an acidified solution of compound (E) gives a precipitate (F) soluble in dil. HNO<sub>3</sub>. After boiling this solution when an excess of NH<sub>4</sub>OH is added, a blue coloured compound (G) is formed. To this solution on addition of acetic acid and aqueous potassium ferrocyanide a chocolate precipitate (H) is obtained. On addition of an aqueous solution of barium chloride to an aqueous solution of (E), a white precipitate insoluble in HNO<sub>3</sub> is obtained. Identify from (A) to (H).

$$[\textbf{Hint}: \quad \text{FeS} + \text{H}_2\text{SO}_4 \longrightarrow \text{FeSO}_4 + \text{H}_2\text{S} \\ (A) \qquad \qquad (B) \\ \\ \text{H}_2\text{S} + [O] \longrightarrow \text{H}_2\text{O} + \text{S} \\ \text{From acid} \qquad (D) \\ (\text{HNO}_3) \\ \\ \text{H}_2\text{S} + \text{CuSO}_4 \longrightarrow \text{CuS} + \text{H}_2\text{SO}_4 \\ (E) \qquad \qquad (F) \\ \text{Soluble in HNO}_3 \\ \\ \text{2HNO}_3 \longrightarrow \text{H}_2\text{O} + 2\text{NO}_2 + [O] \\ \\ \text{CuS} + 2\text{HNO}_3 + [O] \longrightarrow \text{Cu}(\text{NO}_3)_2 + \text{H}_2\text{O} + \text{S} \\ \\ \text{Cu}(\text{NO}_3)_2 + 4\text{NH}_4\text{OH} \longrightarrow \text{Cu}(\text{NH}_3)_4(\text{NO}_3)_2 + 4\text{H}_2\text{O} \\ \\ \text{Cu}(\text{NH}_3)_4(\text{NO}_3)_2 + 4\text{CH}_3\text{COOH} \longrightarrow \text{Cu}(\text{NO}_3)_2 + 4\text{CH}_3\text{COONH}_4 \\ \\ \text{2Cu}(\text{NO}_3)_2 + \text{K}_4\text{Fe}(\text{CN})_6 \longrightarrow \text{Cu}_2[\text{Fe}(\text{CN})_6] + 4\text{KNO}_3 \\ \\ \text{(E)} \qquad \qquad \text{CuCl}_2 + \text{BaSO}_4 \\ \\ \text{Insoluble in HNO}_3 \end{bmatrix}$$

- 3. An aqueous solution of an inorganic compound (X) gives the following reactions:
  - (a) When an aqueous solution of barium chloride is added, a precipitate insoluble in dil. HCl is obtained.
  - (b) Addition of excess of KI gives a brown precipitate which turns white on addition of excess of hypo.
  - (c) With an aqueous solution of potassium ferrocyanide a chocolate coloured precipitate is formed.

Identify (X) and give equations for the above reactions.

[Hint: The compound (X) is 
$$CuSO_4 \cdot 5H_2O$$
(a)  $CuSO_4 + BaCl_2 \longrightarrow BaSO_4 + CuCl_2$ 
Insoluble
(b)  $2CuSO_4 + 4KI \longrightarrow Cu_2I_2 + 2K_2SO_4 + I_2$ 
White
$$I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6$$
(c)  $2CuSO_4 + K_4Fe(CN)_6 \longrightarrow Cu_2Fe(CN)_6 + 2K_2SO_4$ 

$$Chocolate ppt.$$

**4.** A certain metal (A) is boiled in dilute nitric acid to give a salt (B) and an oxide of nitrogen (C). An aqueous solution of (B) with brine solution gives a precipitate (D) which is soluble in ammonium hydroxide. On adding aqueous solution of (B) to hypo solution, a white precipitate (E) is obtained. (E) on standing turns to a black compound (F). Identify (A) to (F).

[Ans. (A) = Silver; (B) = AgNO<sub>3</sub>; (C) = NO; (D) = AgCl;

$$(E) = Ag_2S_2O_3; (F) = Ag_2S.$$
**Reactions:**  $3Ag + 4HNO_3 \longrightarrow 3AgNO_3 + NO + 2H_2O$ 

$$(A) \qquad (B) \qquad (C)$$

$$AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$$

$$(D)$$

$$AgCl + 2NH_4OH \longrightarrow Ag(NH_3)_2Cl + 2H_2O$$
Soluble
$$2AgNO_3 + Na_2S_2O_3 \longrightarrow Ag_2S_2O_3 + 2NaNO_3$$

$$(E) \text{ White ppt.}$$

$$Ag_2S_2O_3 + H_2O \longrightarrow Ag_2S + H_2SO_4 ]$$

$$(F) \text{ Black}$$

5. A pale blue crystalline substance (X) when heated upto 300°C gives a white solid (Y) which can restore blue colour with moisture. Solution of either (X) or (Y) forms (Z) with excess of ammonia which imparts deep blue colour to solution. Write formulae for (X), (Y) and (Z).

[Ans. 
$$(X) = \text{CuSO}_4.5\text{H}_2\text{O}; (Y) = \text{CuSO}_4; (Z) = \text{Cu}(\text{NH}_3)_4\text{SO}_4$$
]

- **6.** (i) A white amorphous powder (A) on strong heating gives a colourless non-combustible gas (B) and solid (C).
  - (ii) The gas (B) turns lime water milky and turbidity disappears with the passage of excess of gas.
  - (iii) The solution of (C) in dil. HCl gives a white precipitate with an aqueous solution of  $K_4$ Fe $(CN)_6$ .
  - (iv) The solution (A) in dilute HCl gives a white precipitate
     (D) on passing H<sub>2</sub>S in presence of excess of NH<sub>4</sub>OH.
     Identify (A) to (D) and give chemical equations for the reactions.

    [Roorkee 1993]

$$[\textbf{Hint}: ZnCO_3 \longrightarrow CO_2 + ZnO \atop (A) \qquad (B) \qquad (C) \atop (B) \qquad (C) \qquad CO_2 + Ca(OH)_2 \longrightarrow CaCO_3 \qquad \frac{CO_2}{Milky} \qquad Ca(HCO_3)_2 \atop Soluble \qquad Soluble \qquad ZnO + HCl \longrightarrow ZnCl_2 \qquad \frac{K_4Fe(CN)_6}{White \ ppt.} \qquad ZnCO_3 + HCl \longrightarrow ZnCl_2 \atop Solution \qquad ZnCl_2 + NH_4OH + H_2S \longrightarrow ZnS \qquad ] \\ White \ ppt. \qquad (D)$$

- 7. A white substance when heated in a test tube, produced a colourless, odourless gas leaving a residue, yellow when hot and white on cooling. The residue was dissolved in dil. HCl, made alkaline with ammonium chloride and ammonium hydroxide and H<sub>2</sub>S gas passed through it. A white precipitate was obtained.
  - (i) What was the original substance?
  - Write the equation for the action of heat.
  - (iii) What was the white precipitate formed with H<sub>2</sub>S? [Ans. (i)  $ZnCO_3$ ; (ii)  $ZnCO_3 \longrightarrow ZnO + CO_2$ ; (iii) ZnS]
- **8.** (i) An aqueous solution of a white coloured compound (A) on reaction with HCl gives a white precipitate of compound (B).
  - (ii) (B) becomes soluble in chlorine water with formation of
  - (iii) (C) reacts with KI to give a precipitate which becomes soluble in excess of it forming a compound (D). The compound (D) is used for detecting ammonium salts.
  - (iv) (B) and (C) both on treatment with SnCl<sub>2</sub> gives a grey precipitate of (E).
  - (v) When conc. H<sub>2</sub>SO<sub>4</sub> is added slowly into a mixture of cold solution of (A) and FeSO<sub>4</sub>, a brown ring compound (F) is formed.

Identify (A) to (F) and give chemical equations for the reactions at steps (i) to (v). [Roorkee 1997] [Ans.  $(A) = Hg_2(NO_3)_2$ ;  $(B) = Hg_2Cl_2$ ;  $(C) = HgCl_2$ ;  $(D) = K_2HgL_4$ ;  $(E) = \text{Hg}; (F) = \text{FeSO}_4 \cdot \text{NO}.$ 

**Reactions :** (i)  $Hg_2(NO_3)_2 + 2HCl \longrightarrow Hg_2Cl_2 + 2HNO_3$ 

(ii)  $Hg_2Cl_2 + 2Cl(Chlorine water) \longrightarrow 2HgCl_2$ 

(iii) 
$$HgCl_2 + 4KI \longrightarrow K_2HgI_4 + 2KCl$$

(iv) 
$$\begin{array}{ccc} \text{Hg}_2\text{Cl}_2 + \text{SnCl}_2 & \longrightarrow & 2\text{Hg} + \text{SnCl}_4 \\ \text{(B)} & \text{(E)} & \text{(E)} \\ \text{HgCl}_2 + \text{SnCl}_2 & \longrightarrow & \text{Hg} + \text{SnCl}_4 \\ \text{(C)} & \text{(E)} & \text{(E)} \end{array}$$

(v) 
$$Hg_2(NO_3)_2 + H_2SO_4 \longrightarrow Hg_2SO_4 + 2HNO_3$$
  
 $2HNO_3 \longrightarrow H_2O + 2NO + 3[O]$   
 $2FeSO_4 + [O] + H_2SO_4 \longrightarrow Fe_2(SO_4)_3 + H_2O$   
 $FeSO_4 + NO \longrightarrow FeSO_4 NO \quad (Brown ring)]$ 

- 9. (i) A blue coloured compound (A) on heating gives two products, (B) and (C).
  - A metal (D) is deposited on passing hydrogen through heated (B).
  - (iii) The solution of (B) in HCl on treatment with K<sub>4</sub>Fe(CN)<sub>6</sub> gives a chocolate brown coloured precipitate of compound (E).
  - (iv) (C) turns lime water milky which disappears on continuous passage of (C) forming a compound (F).

Identify (A) to (F) and give chemical equations for the reactions at steps (i) to (iv). [Roorkee 1997] [Ans. (A) =  $CuCO_3$ ; (B) = CuO; (C) =  $CO_2$ ; (D) = Cu;

 $(E) = \text{Cu}_2\text{Fe}(\text{CN})_6; \quad (F) = \text{Ca}(\text{HCO}_3)_2.$ Reactions: (i)

 $CuCO_3 \longrightarrow CuO + CO_2$ (A) (B)

(ii) 
$$CuO + H_2 \longrightarrow Cu + H_2O$$

$$(D)$$

(iii) 
$$\text{CuO} + 2\text{HCl} \longrightarrow \text{CuCl}_2 + \text{H}_2\text{O}$$
  
 $2\text{CuCl}_2 + \text{K}_4\text{Fe}(\text{CN})_6 \longrightarrow \text{Cu}_2\text{Fe}(\text{CN})_6 + 4\text{KCl}$   
(E)

(iv) 
$$\begin{array}{ccc} CO_2 + Ca(OH)_2 & \longrightarrow & CaCO_3 + H_2O \\ & & CaCO_3 + CO_2 + H_2O & \longrightarrow & Ca(HCO_3)_2 \end{array} ]$$

- **10.** (i) A black mineral (A) on heating in presence of air gives a gas (B).
  - The mineral (A) on reaction with dilute H<sub>2</sub>SO<sub>4</sub> gives a gas (C) and the solution of a compound (D).
  - (iii) On passing gas (C) into an aqueous solution of (B), a white turbidity is obtained.
  - (iv) The aqueous solution of compound (D) on reaction with potassium ferricyanide gives a blue compound (E).

Identify (A) to (E) and give chemical equation for reactions at steps (i) to (iv),

[**Hint**: (A) = FeS;  $(B) = \text{SO}_2$ ;  $(C) = \text{H}_2\text{S}$ ;  $(D) = \text{FeSO}_4$ ;  $(E) = K^{\dagger}Fe^{II}[Fe^{III}(CN)_{6}]$ 

(i) 
$$2\text{FeS} + 3\text{O}_2 \longrightarrow 2\text{FeO} + 2\text{SO}_2$$
(A) (B)

(ii) 
$$FeS + H_2SO_4 \longrightarrow FeSO_4 + H_2S$$
(D) (C)

(iii) 
$$2H_2S + SO_2 \longrightarrow 2H_2O + 3S$$
  
(C) (B) Turbidity

$$\begin{array}{ccc} \text{(iv)} & & \text{FeSO}_4 + \text{ } \text{K}_3\text{Fe}(\text{CN})_6 \longrightarrow \text{KFe}[\text{Fe}(\text{CN})_6] + \text{ } \text{K}_2\text{SO}_4] \\ & & \text{(\it{E}) Blue} \end{array}$$

11. A certain inorganic compound (A) on heating loses its water of crystallization. On further heating a blackish brown powder (B) and two oxides of sulphur, (C) and (D) are obtained. The powder (B) on boiling with hydrochloric acid gives a yellow solution (E). When  $H_2S$  is passed in (E) a white turbidity (F) and a apple green colour (G) are obtained. The solution (E) on treatment with thiocyanate ions gives a blood red coloured compound (H). Identify from (A) to (H).

[Ans. (A) =  $FeSO_4$ ·7H<sub>2</sub>O; (B) =  $Fe_2O_3$ ; (C) =  $SO_2$ ; (D) =  $SO_3$ ;  $(E) = \operatorname{FeCl}_3$ ; (F) = S;  $(G) = \operatorname{FeCl}_2$ ;  $(H) = \operatorname{Fe(SCN)}_3$ .

Reaction:

FeSO<sub>4</sub>7H<sub>2</sub>O 
$$\xrightarrow{\text{Heat}}$$
 FeSO<sub>4</sub>  $\xrightarrow{\text{Heat}}$  Fe<sub>2</sub>O<sub>3</sub> + SO<sub>2</sub> + SO<sub>3</sub>
(A) Fe<sub>2</sub>O<sub>3</sub> + 6HCl  $\longrightarrow$  2FeCl<sub>3</sub> + 3H<sub>2</sub>O

2FeCl<sub>3</sub> + H<sub>2</sub>S  $\longrightarrow$  2FeCl<sub>2</sub> + 2HCl + S
(G) (F)

FeCl<sub>3</sub> + 3SCN<sup>-</sup>  $\longrightarrow$  Fe(SCN)<sub>3</sub> + 3Cl<sup>-</sup>]

- **12.** Compound (A) is a light green solid. It gives following tests:
  - (a) It dissolves in dilute H<sub>2</sub>SO<sub>4</sub>. No gas is evolved.
  - (b) A drop of KMnO<sub>4</sub> is added to the above solution. The pink colour is decolourised.
  - (c) Compound (A) is heated strongly. Gases (B) and (C) with pungent smell come out and a brown residue (D) is left.
  - (d) The gaseous mixture is passed into a dichromate solution, it turns green.

- (e) The green solution from reaction 'd' gives a white precipitate (E) with a solution of barium nitrate.
- (f) The residue (D) from reaction 'c' on heating with charcoal in a reducing flame, gave a magnetic substance. Name the compounds (A), (B), (C), (D) and (E).

[Ans. (A) =  $FeSO_4 \cdot 7H_2O$ ; (B) =  $SO_2$ ; (C) =  $SO_3$ ; (D) =  $Fe_2O_3$ ; (E) =  $BaSO_4$ 

(a) (A) dissolves in dilute H<sub>2</sub>SO<sub>4</sub>. No gas is evolved.

(b)  $10\text{FeSO}_4 + 2\text{KMnO}_4 + 8\text{H}_2\text{SO}_4 \longrightarrow 5\text{Fe}_2(\text{SO}_4)_3 + \text{K}_2\text{SO}_4 + 2\text{MnSO}_4 + 8\text{H}_2\text{C}_4 + 8\text{H}_2\text{$ 

(c)  $2\text{FeSO}_4 \cdot 7\text{H}_2\text{O} \longrightarrow \text{Fe}_2\text{O}_3 + 2\text{SO}_2 + 2\text{SO}_3 + 14\text{H}_2\text{O}$ (A) (B) (C)

(d)  $SO_2$  reduces acidified  $K_2Cr_2O_7$ .  $K_2Cr_2O_7 + H_2SO_4 + 3SO_2 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O_4$ .

- (e)  $SO_4^{2-} + Ba(NO_3)_2 \longrightarrow BaSO_4 + 2NO_3^{-}$
- (f)  $Fe_2O_3 + 3C \longrightarrow 2Fe + 3CO$
- 13. Compound (A),
  - (i) On strong heating gives two oxides of sulphur.
  - (ii) On adding aqueous NaOH solution to its aqueous solution, a dirty green precipitate is obtained which starts turning brown on exposure to air.

Identify (A) and give chemical equations. [Roorkee 1993] [Hint:  $(A) = FeSO_4$ 

$$2FeSO_{4} \xrightarrow{Heat} Fe_{2}O_{3} + SO_{2} + SO_{3}$$

$$FeSO_{4} + 2NaOH \longrightarrow Fe(OH)_{2} + Na_{2}SO_{4}$$

$$Fe(OH)_{2} \xrightarrow{[O]} Fe(OH)_{3}]$$

- **14.** A light bluish green crystalline compound corresponds to the following tests:
  - (i) Its aqueous solution gives a brown precipitate or colouration with alkaline K<sub>2</sub>[HgI<sub>4</sub>].
  - (ii) Its aqueous solution gives a blue colour with K<sub>3</sub>Fe(CN)<sub>6</sub> solution.
  - (iii) Its solution in HCl gives a white precipitate with BaCl<sub>2</sub> solution.

Identify the ions present and suggest the formula of the compound. [I.I.T. 1992]

[Ans. The ions present are NH<sub>4</sub>, Fe<sup>2+</sup> and SO<sub>4</sub><sup>2-</sup>. The formula of the compound is (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>·FeSO<sub>4</sub>·6H<sub>2</sub>O]

- **15.** (i) The yellow coloured precipitate of compound (A) is formed on passing H<sub>2</sub>S through a neutral solution of a salt (B).
  - (ii) (A) is soluble in hot dilute HNO<sub>3</sub>, but insoluble in yellow ammonium sulphide.
  - (iii) The solution of (B) on treatment with small quantity of NH<sub>3</sub> gives white precipitate which becomes soluble in excess of it forming a compound (C).
  - (iv) The solution of (B) gives white precipitate with small concentration of KCN which becomes soluble in excess of this reagent forming a compound (D).
  - (v) The solution of (D) on treatment with  $H_2S$  gives (A).
  - (vi) The solution of (B) in dilute HCl on treatment with a solution of BaCl<sub>2</sub> gives white precipitate of compound (E) which is insoluble in conc. HNO<sub>3</sub>.

Identify (A) to (E) and give chemical equations for the reactions at steps (i) and (iii) to (vi). [Roorkee 1998] [Hint: (B) is CdSO<sub>4</sub> which gives a yellow compound by passing H<sub>2</sub>S through its solution. It gives a white ppt. with BaCl<sub>2</sub> soln. The ppt. is insoluble in conc. HNO<sub>3</sub>. It suggests that SO<sub>4</sub><sup>2-</sup> ion is present in the salt.

(i) 
$$CdSO_4 + H_2S \longrightarrow CdS + H_2SO_4$$
  
(ii)  $CdSO_4 + BaCl_2 \longrightarrow BaSO_4 + CdCl_2$ 

(a) 
$$CdSO_4 + BaCl_2 \longrightarrow BaSO_4 + CdCl_2$$
  
(B) (E) Insoluble in water  $CdS + 2HNO_3 \longrightarrow Cd(NO_3)_2 + H_2S$ 

$$\begin{array}{c} \text{Soluble} \\ \text{CdS} + (\text{NH}_4)_2 S_x \longrightarrow \text{Insoluble} \\ \text{Yellow ammonium} \\ \text{Sulphide} \end{array}$$

(iii) 
$$CdSO_4 + 2NH_4OH \longrightarrow Cd(OH)_2 + (NH_4)_2SO_4$$
  
 $Cd(OH)_2 + 4NH_4OH \longrightarrow Cd(NH_3)_4(OH)_2 + 4H_2O$   
(C) Soluble

(iv) 
$$CdSO_4 + 2KCN \longrightarrow Cd(CN)_2 + K_2SO_4$$
White ppt.
$$Cd(CN)_2 + 2KCN \longrightarrow K_2Cd(CN)_4$$
(D) Soluble

(v) 
$$K_2Cd(CN)_4$$
 +  $H_2S \longrightarrow CdS + 2KCN + 2HCN$ 

- **16.** (i) An aqueous solution of a compound (A) is acidic towards litmus and (A) is sublimed at about 300°C.
  - (ii) (A) on treatment with an excess of NH<sub>4</sub>CNS gives a red coloured compound (B) and on treatment with a solution of K<sub>4</sub>Fe(CN)<sub>6</sub> gives a blue coloured compound (C).
  - (iii) (A) on heating with excess of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in presence of conc. H<sub>2</sub>SO<sub>4</sub> gives deep red vapours of (D).
  - (iv) On passing vapours of (D) into a solution of NaOH and then adding the solution of acetic acid and lead acetate, a yellow precipitate of compound (E) is obtained.

Identify (A) to (E) and give chemical equations for the reactions at steps (ii) to (iv). [Roorkee 1998] [Hint: (A) is FeCl<sub>3</sub>. It gives red colour of Fe(CNS)<sub>3</sub> with NH<sub>4</sub>CNS

Hint: (A) is FeCl<sub>3</sub>. It gives red colour of Fe(CNS)<sub>3</sub> with NH<sub>4</sub>CN and chromyl chloride test for Cl<sup>-</sup> ion. The reactions are:

(i) 
$$FeCl_3 + 3H_2O \rightleftharpoons Fe(OH)_3 + 3HCl$$
(A) (Acidic)

(A) sublimes at 300°C

(ii) FeCl<sub>3</sub> + 3NH<sub>4</sub>CNS 
$$\longrightarrow$$
 Fe(CNS)<sub>3</sub> + 3NH<sub>4</sub>Cl  
(B) Red  
4FeCl<sub>3</sub> + 3K<sub>4</sub>Fe(CN)<sub>6</sub>  $\longrightarrow$  Fe<sub>4</sub>[Fe(CN)<sub>6</sub>]<sub>3</sub> + 12KCl  
(C) Blue

(iii)  $4\text{FeCl}_3 + 9\text{H}_2\text{SO}_4 + 3\text{K}_2\text{Cr}_2\text{O}_7 \longrightarrow 6\text{CrO}_2\text{Cl}_2 + 2\text{Fe}_2(\text{SO}_4)_3 + 3\text{K}_2\text{SO}_4 + 9\text{H}_2\text{O}_4$ (D) Red vapours

(iv) 
$$CrO_2Cl_2 + 4NaOH \longrightarrow 4Na_2CrO_4 + 2NaCI + 2H_2O$$
  
 $Na_2CrO_4 + (CH_3COO)_2Pb \longrightarrow PbCrO_4 + 2CH_3COONa]$   
(E) Yellow ppt.

- 17. Pyrolusite on heating with KOH in the presence of air gives a dark green compound (A). The solution of (A) on treatment with  $H_2SO_4$  gives a purple coloured compound (B), which gives following reactions.
  - (i) KI on reaction with alkaline solution of (B) changes into a compound (C).

- (ii) The colour of the compound (B) disappears on treatment with the acidic solution of FeSO<sub>4</sub>.
- (iii) With conc. H<sub>2</sub>SO<sub>4</sub> compound (B) gives (D) which can decompose to yield (E) and oxygen.

Identify (A) to (E) and write balanced chemical equations for the formation of (A) and (B) and for steps (i) to (iii).

[Roorkee 1999]

[Hint: 
$$2MnO_2 + 4KOH + O_2 \longrightarrow 2K_2MnO_4 + 2H_2O$$
(Air) (A) Dark green
$$3K_2MnO_4 + 2H_2SO_4 \longrightarrow 2KMnO_4 + MnO_2 + 2K_2SO_4 + 2H_2O$$
(B) Purple
(i)  $2KMnO_4 + H_2O + KI \longrightarrow KIO_3 + 2MnO_2 + 2KOH$ 
(ii)  $2KMnO_4 + 8H_2SO_4 + 10FeSO_4 \longrightarrow K_2SO_4 + 2MnSO_4$ 

$$(11) 2KVM1O_4 + 8H_2SO_4 + 10FeSO_4 \longrightarrow K_2SO_4 + 2VM1SO_4 + 5Fe_2(SO_4)_3 + 8H_2O_4$$

(iii) 
$$2\text{KMnO}_4 + \text{H}_2\text{SO}_4 \longrightarrow \text{Mn}_2\text{O}_7 + \text{K}_2\text{SO}_4 + \text{H}_2\text{O}_4$$

$$(D)$$

$$2\text{Mn}_2\text{O}_7 \longrightarrow 4\text{MnO}_2 + 3\text{O}_2$$

18. An aqueous blue coloured solution of a transition metal sulphate reacts with H<sub>2</sub>S in acidic medium to give a black precipitate (A) which is insoluble in warm aqueous solution of KOH. The blue solution on treatment with KI in weakly acidic medium turns yellow and produces a white precipitate (B). Identify the transition metal ion. Write the chemical reactions involved in the formation of (A) and (B).

[L.I.T. 2000]

[Hint: The transition metal ion is Cu<sup>2+</sup>.

$$\begin{array}{c} \text{CuSO}_4 + \text{H}_2\text{S} \longrightarrow \text{CuS} + \text{H}_2\text{SO}_4 \\ \text{Blue coloured} & (A) \\ \text{solution} & \text{Black ppt.} \\ \text{CuSO}_4 + 2\text{KI} \longrightarrow \text{CuI}_2 + \text{K}_2\text{SO}_4 \\ 2\text{CuI}_2 \longrightarrow \text{Cu}_2\text{I}_2 + \text{I}_2 \text{]} \\ & (B) \\ \text{White not} \end{array}$$

- 19. (i) An ore (A) on roasting with sodium carbonate and lime in the presence of air gives two compounds, (B) and (C).
  - (ii) The solution of (B) in conc. HCl on treatment with potassium ferrocyanide gives a blue colour or precipitate of compound (D).
  - (iii) The aqueous solution of (C) on treatment with conc.  $H_2SO_4$  gives a yellow coloured compound (E).
  - (iv) Compound (E) when treated with KCl gives an orangered compound (F) which is used as an oxidising reagent.
  - (v) The solution of (F) on treatment with oxalic acid and then with an excess of potassium oxalate gives blue crystals of compound (G).

Identify (A) to (G) and give balanced chemical equations for reactions at steps (i) to (v). [Roorkee 2000] [Hint: The ore is chromite,  $FeOCr_2O_3$ .

(i)  $^{4}\text{FeO Cr}_{2}\text{O}_{3} + ^{8}\text{Na}_{2}\text{CO}_{3} + ^{7}\text{O}_{2} \xrightarrow{\text{Lime}} ^{\text{Lime}} ^{2}\text{Fe}_{2}\text{O}_{3} + ^{8}\text{Na}_{2}\text{CrO}_{4}$   $^{(B)} \cdot ^{(C)} \cdot ^{(C)} + ^{8}\text{CO}_{2}$ 

(ii) 
$$Fe_2O_3 + 6HC1 \longrightarrow 2FeCl_3 + 3H_2O$$

$$\begin{array}{c} \text{4FeCl}_3 + 3\text{K}_4\text{Fe}(\text{CN})_6 \longrightarrow & \text{Fe}_4[\text{Fe}(\text{CN})_6]_3 + 12\text{KCl} \\ \text{Prussian blue} \end{array}$$

(iii) 
$$2Na_2CrO_4 + H_2SO_4 \longrightarrow Na_2Cr_2O_7 + Na_2SO_4 + H_2O$$

$$(C)$$
Yellow coloured

(iv) 
$$Na_2Cr_2O_7 + 2KCl \longrightarrow K_2Cr_2O_7 + 2NaCl$$

(F)

Orange-red

(v) 
$$K_2Cr_2O_7 + 4H_2SO_4 + 3H_2C_2O_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 6CO_2 + 7H_2O$$

$$Cr_2(SO_4)_3 + 6K_2C_2O_4 \longrightarrow 2K_3[Cr_2(C_2O_4)_3] + 3K_2SO_4]$$
(G)
Blue crystals

**20.** Complete the following by identifying (A) to (F).

(i) 
$$\text{CuSO}_4 \cdot 5\text{H}_2\text{O} \xrightarrow{100^{\circ}\text{C}} (A) \xrightarrow{230^{\circ}\text{C}} (B) \xrightarrow{800^{\circ}\text{C}} (C) + (D)$$

(ii) AgNO<sub>3</sub> 
$$\xrightarrow{\text{Red hot}}$$
 (E) + (F) + O<sub>2</sub> [Roorkee 2000]

  - (a) + 4

(b) + 6

(c) + 2

(d) + 3

Ans. (d)

[Hint:  $Sc^{3+}$  has  $3d^{0}$  configuration while  $Zn^{2+}$  has  $3d^{10}$  configuration. Hence, these ions are colourless.]

German silver Cu 56%,

Common metal is copper.]

11. Which of the following pairs of ions is colourless?

- 12. The lanthanide contraction relates to :
  - (a) atomic radii
- (b) atomic as well as  $M^{3+}$  radii

[E.A.M.C.E.T. (Engg.) 2004]

- (c) valence electrons
- (d) oxidation states

Ans. (b)

- 13. For successive members of the first row transition elements are listed below with their atomic numbers. Which one of them is expected to have the highest third ionisation enthalpy? [C.B.S.E. 2005]
  - (a) Vanadium (Z = 23)
- (b) Manganese (Z = 25)
- (c) Chromium (Z=24)
- (d) Iron (Z = 26)

Ans. (b)

[**Hint**: 
$$M^{2+} - e \xrightarrow{\text{3rd}} M^{3+}$$

 $Mn^{2+}$  has the most stable configuration, i.e.,  $3d^5$  (all the five d-orbitals are singly occupied). Hence, to remove electron from Mn<sup>2+</sup> ion requires more energy, *i.e.*, the third ionisation enthalpy of manganese is highest.]

- 14. Green vitriol is formed by:
  - (a)  $FeS_2 + CO$
- (b)  $FeS_2 + H_2O + CO_2$
- (c)  $FeS_2 + H_2O + O_2$
- (d)  $FeS_2 + CO + CO_2$

Ans. (c)

[Hint:  $2FeS_2 + 7O_2 + 2H_2O \longrightarrow 2FeSO_4 + 2H_2SO_4$ ]

- 15. Stainless steel does not rust because:
  - (a) nickel present in it does not rust
  - (b) chromium and nickel combine with iron
  - (c) chromium forms an oxide layer and protects iron from rusting
  - (d) iron forms a hard chemical compound with chromium present in it

Ans. (c)

- 16. Which of the following forms with an excess of CN, a complex having coordination number two? [A.I.I.M.S. 2004]
  - (a) Cu<sup>2+</sup>

(b) Ag<sup>+</sup>

(c) Ni<sup>2+</sup>

(d) Fe<sup>2</sup>

Ans. (b)

[Hint:  $AgCN + CN^{-} \longrightarrow [Ag(CN)_{2}]^{-}$ ]

- 17. Of the following outer electronic configurations of atoms, the highest oxidation state is achieved by which one of them?
  - (a)  $(n-1)d^8ns^2$
- (b)  $(n-1)d^5ns^1$
- (c)  $(n-1)d^3ns^2$
- (d)  $(n-1)d^5ns^2$

Ans. (d)

- **18.** The compound used in enrichment of uranium for nuclear power plant is: [A.I.I.M.S. 2006]
  - (a)  $U_3O_8$
- (b) UF<sub>6</sub>
- (c)  $UO_2(NO_3)_2$
- (d) UCl

Ans. (b)

- 19. Lanthanide contraction is caused due to : [A.I.E.E.E. 2006]
  - (a) the appreciable shielding on outer electrons by 4f electrons from the nuclear charge
  - (b) the appreciable shielding on outer electrons by 5d electrons from the nuclear charge

- (c) the same effective nuclear charge from Ce to Lu.
- (d) the imperfect shielding on outer electrons by 4f electrons from the nuclear charge

Ans. (d

**20.** The spin only magnetic moment [in units of Bohr magneton] of Ni<sup>2+</sup> in aqueous solution would be (At. No. 28):

[A.I.E.E.E. 2006]

(a) 2.84

(b) 4.90

(c) 0

(d) 1.73

Ans. (a)

[Hint: Ni<sup>2+</sup> has  $3d^8$  configuration, *i.e.*, 2 unpaired electrons are present. Thus, magnetic moment  $= \sqrt{n(n+2)} = \sqrt{2 \times 4}$ =  $\sqrt{8} = 2.84$  B.M.]

- 21. In which of the following pairs are both the ions coloured in aqueous solution? [C.B.S.E. 2006]
  - (a)  $Sc^{3+}$ ,  $Co^{2+}$
- (b) Ni<sup>2+</sup>, Cu<sup>+</sup>
- (c)  $Ni^{2+}$ ,  $Ti^{3+}$
- (d)  $Se^{3+}$ ,  $Ti^{3+}$

[At. Nos. Sc = 21, Ti = 22, Ni = 28 and Cu = 29]

Ans. (c

[Hint: Unpaired electrons are present in  $\mathrm{Ni}^{2+}$  and  $\mathrm{Ti}^{3+}$ 

- 22. Arrange the following ions in their magnetic moment:
  - (i)  $V^{4+}$  (ii)  $Mn^{4+}$  (iii)  $Fe^{3+}$  (iv)  $Ni^{2+}$

[At. Nos. V = 23, Mn = 25, Fe = 26, Ni = 28]

- (a) (ii) > (iii) > (i) > (iv)
- (b) (iii) > (iv) > (ii) > (i)
- (c) (iii) > (ii) > (iv) > (i)
- (d) (i) < (iv) < (iii) < (ii)

Ans. (c)

[**Hint**:  $V^{4+}$ [Ar]3 $d^{1}$ , Mn<sup>4+</sup>[Ar]3 $d^{3}$ , Fe<sup>3+</sup>[Ar]3 $d^{5}$ , Ni<sup>2+</sup>[Ar]3 $d^{8}$ ]

	ODSCOTTVC GOC		
Set :	I: This set contains questions with one answer.		
	Among d-block elements, the most abundant element	11.	Among the following outermost configurations of transition
1.	belongs to:	11.	metals, which shows the highest oxidation state:
	(a) first transition series		[C.B.S.E. (P.M.T.) 2009]
	(b) second transition series		(a) $3d^3, 4s^2$
	(c) third transition series		(c) $3d^5, 4s^2$
	(d) fourth transition series	10	
2.	Which of the following is not the characteristic of transition	12.	In the first transition series, the highest oxidation state is
	metals?		exhibited by:
	(a) They are all metals		(a) Mn
	(b) They show variable oxidation states which always differ	12	_ (-)
	by two units	15.	Which of the following ions is coloured in solution?
	(c) They are paramagnetic		(a) $Zn^{2+}$ $\Box$ (b) $Ti^{4+}$ $\Box$
	(d) They easily form complexes		(c) $Cu^+$ $\Box$ (d) $V^{3+}$ $\Box$
3.	The correct order of ionisation energy is:	14.	
٠.	(a) $Cu > Ag > Au$ $\Box$ (b) $Cu > Au > Ag$ $\Box$		ion of [CoCl <sub>4</sub> ] <sup>2-</sup> ?
	(c) $Au > Cu > Ag$		(a) 5
4.	The first transition element is:		(c) 3
	(a) scandium		[Hint : $Co^{2+}$ E.C. = 2, 8, 8 + 7 $\boxed{\uparrow\downarrow\uparrow\uparrow\downarrow\uparrow\uparrow\uparrow\uparrow}$ ]
	(c) nickel		3d
5.	The general electronic configuration of transition elements	15.	Which of the following has the maximum number of unpaired
٠.	is:		d electrons?
	(a) $(n-1)d^{1-5}$		(a) $Zn$ $\Box$ (b) $Fe^{2+}$ $\Box$
	(a) $(n-1)d^{1-5}$		(c) $Ni^{3+}$ $\square$ (d) $Cu^{+}$ $\square$
6.	The property, which is not characteristic of transition metals,	16.	Colour in transition metal compounds is attributed to:
0.	is: [V.I.T.E.E.E. 2008]		(a) small size of metal ions
	(a) variable oxidation states		(b) absorption of light in UV region
•	(b) tendency to form complexes		(c) moderate ionisation energy
	(c) formation of coloured compounds		(d) incomplete $(n-1)$ $d$ subshell
	(d) natural radioactivity	17.	
7.	in a contract of the contract		(a) $f$ -block element $\Box$ (b) $d$ -block element $\Box$
	above the element with atomic number 43 in the same		(c) $p$ -block element $\square$ (d) $s$ -block element $\square$
	periodic group is:	18.	
	(a) $1s^2, 2s^22p^6, 3s^23p^63d^5, 4s^2$		(a) $[Ar]3d^9, 4s^2$
			(c) $[Ar]3d^8, 4s^2$
	(b) $1s^2, 2s^22p^6, 3s^23p^63d^{10}, 4s^24p^5$	10	Which metal has the highest melting point?
	(c) $1s^2, 2s^22p^6, 3s^23p^63d^6, 4s^1$	12.	(a) Platinum
	(d) $1s^2, 2s^22p^6, 3s^23p^63d^{10}, 4s^14p^6$		(c) Tungsten
8.	Chromium has the electronic configuration:	20.	Transition metals show paramagnetism: [B.H.U. 2005]
	(a) $3s^23p^63d^4$ , $4s^2$	20.	(a) due to characteristic configuration
	(c) $3s^23p^63d^6$ $\square$ (d) none of these $\square$		(b) high lattice energy
9.	The number of d electrons in Fe <sup>2+</sup> (at. no. of iron = 26) is not		(c) due to variable oxidation states
7,	•		(d) due to unpaired electrons
	equal to that of:	21	Zr and Hf have almost equal atomic and ionic radii because:
	(a) $p$ electrons in neon (at. no. = 10)	21.	(a) of diagonal relationship
	(-),,		(b) of lanthanide contraction
	(c) $d$ electrons in Fe . $\square$ (d) $p$ electrons in Cl <sup>-</sup> (at. no. of Cl = 17)		(c) of actinide contraction
10	(a) P		(d) both belong to same transition series
10.	The maximum number of unpaired electrons are in:	22.	
	(a) $Fe^{2+}$		2+
	(c) Fe <sup>4+</sup>		
	(c) 10 L (d) 10 L	1	(c) $Ti^{2+}$ $\Box$ (d) $V^{2+}$ $\Box$

23.	The yellow colour of chromates changes to orange on acidification due to formation of:	36.	The effect of mineral acids on the coinage metals: (a) decreases from Cu to Au	
	2.		(b) increases from Cu to Au	
	•		(c) remains the same  (d) cannot be predicted	
	(c) $\operatorname{Cr}_2\operatorname{O}_7^{2-}$	37.		
24.	Manganese shows oxidation states from +2 to +7. The most	37.	(a) magnesium	
	oxidising state known in aqueous solution is:		(c) aluminium	
	(a) +7	38.	Copper is extracted from sulphide ore using the method:	
	(c) +3	56.	(a) carbon reduction	
25.	What is the magnetic moment of $K_3[FeF_6]$ ?		(b) carbon monoxide reduction	
	[J.E.E. (Orissa) 2005]		(c) auto reduction	
	(a) 5.91 B.M.	39.	• •	
	(c) 3.87 B.M.	39.	In the extraction of copper from copper pyrites, iron removed as:	115
	[Hint: Fe <sup>3+</sup> E.C. = 2, 8, 8 +5, $\mu = \sqrt{5 \times 7} = 5.91$ B.M.]			
26.	Which of the following is an acidic oxide?		(a) $FeSO_4$	
	(a) $Mn_2O_7$	40	(c) $Fe_3O_4$	
	(c) MnO $\square$ (d) Mn <sub>2</sub> O <sub>3</sub> $\square$	40.	**	
27.	Which one of the following ions is diamagnetic?		(a) a mixture of impure copper and silver	
:	(a) $\operatorname{Cr}^{2+}$ (b) $\operatorname{V}^{2+}$		(b) present in the anodic mud in an electrolytic process	
	(c) $\operatorname{Sc}^{3+}$ $\square$ (d) $\operatorname{Ti}^{3+}$ $\square$		(c) electrolytically refined copper	
28.	Transition metals:	41	(d) copper containing about 2% impurity	
	(a) exhibit inert pair effect $\Box$	41.	The flux used in the smelting of copper ores is:	
	(b) have low melting point		(a) limestone	
	(c) do not show catalytic activity	40	(c) silica	
	(d) exhibit variable oxidation states	42.	In the extraction of copper, metal is formed in the Besser	mer
29.	A metal ion from the first transition has a magnetic moment		converter due to reaction:	_
	(calculated) of 3.87 B.M. How many unpaired electrons are	}	(a) $Cu_2S + 2Cu_2O \longrightarrow 6Cu + SO_2$	님
	expected to be present in the ion?		(b) $Cu_2S \longrightarrow 2Cu + S$	
	(a) 1		(c) Fe + $Cu_2O \longrightarrow 2Cu + FeO$	
	(c) 3		(d) $2Cu_2O \longrightarrow 4Cu + O_2$	
30.	Coinage metals are:	43.	High purity copper metal is obtained by:	_
	(a) normal elements		(a) carbon reduction   (b) hydrogen reduction	
	(b) transition elements	١.,	(c) electrolytic reduction (d) thermite reduction	
	(c) active elements	44.	The melting points of Cu, Ag and Au follow the order:	_
	(d) highly electropositive elements		(a) $Au > Ag > Cu$	
31.	The position of Cu, Ag and Au in the periodic table is in		(c) $Cu > Ag > Au$ $\Box$ (d) $Ag > Au > Cu$ ,	
	between:	45.		_
	(a) alkali and alkaline earth metals	,	(a) to remove moisture and volatile impurities	
	(b) alkali metals and halogens		(b) to oxidise free sulphur	
	(c) VIII group and zinc metals		(c) to decompose pyrites into Cu <sub>2</sub> S and FeS	
	(d) alkaline earth metals and halogens		(d) for all of the above	<u> </u>
32.	Coinage metals show:	46.	In the electrolytic refining of copper, Ag and Au are fou	
	(a) only monovalency $\Box$ (b) only divalency $\Box$		(a) on cathode $\Box$ (b) on anode	
	(c) only trivalency $\Box$ (d) variable valency $\Box$		(c) in the anodic mud $\Box$ (d) in the cathodic mud	
33.	is the best conductor of electricity.	47.	11	_
	(a) Silver		(a) brass	
	(c) Gold	1	(c) german silver	
34.	The electrons present in the penultimate orbit of coinage	48.	Brass is an alloy containing:	_
	metal atoms are:		(a) Cu and Zn	
	(a) 8		(c) Zn and Sn	
	(c) 18	49.		_
35.	When copper is placed in the atmosphere for sufficient time,		(a) Cu and Al	
	a green crust is formed on its surface. The composition of		(c) Cu, Sn and Zn	
	the green crust is:	50.		_
	(a) $Cu(OH)_2$ $\Box$ (b) $CuO$ $\Box$		(a) $CuO$	
	(c) $CuCO_3$		(c) $CuO_2$ $\Box$ (d) $Cu_2O_2$	

51.	-	eated with metallic copper an	1	66.	Silver can be separated from lead by:	
	HCl, a colourless solut	ion is obtained because of	the for-		(a) fractional crystallisation	
	mation of:		ĺ		(b) amalgamation	
	(a) CuCl <sub>2</sub>	$\square$ (b) $Cu_2Cl_2$			(c) filtration $\Box$ (d) addition of zinc	
	(c) H[CuCl <sub>2</sub> ]	☐ (d) H[CuCl <sub>3</sub> ]		67.	Silver sulphide dissolves in sodium cyanide solution to fo	rm
52.	·CuSO <sub>4</sub> ·5H <sub>2</sub> O is called:	•	1		the complex:	
	(a) green vitriol	☐ (b) blue vitriol			(a) $Na_2[Ag(CN)_4]$	
	(c) white vitriol	☐ (d) gypsum			(c) $Na_3[Ag(CN)_4]$ $\square$ (d) all of these	
53.	In the reaction,			68.	Red precipitate is obtained when silver nitrate is added	to:
		$\longrightarrow A + H_2SO_4 + 2HCl; A is:$	:		(a) $K_2CrO_4$ $\Box$ (b) KI	
	(a) Cu <sub>2</sub> Cl <sub>2</sub>	□ (b) Cu			(c) KBr $\square$ (d) Na <sub>2</sub> S <sub>2</sub> O <sub>3</sub>	
	(c) CuSO <sub>4</sub>	(d) CuS		69.	Photographic films or plates have as an essent	tial
54.		CuSO <sub>4</sub> and KI, a white preci			ingredient.	
٠		te has the composition:			(a) silver oxide	
	(a) CuI <sub>2</sub>	☐ (b) Cu <sub>2</sub> I			(c) silver thiosulphate $\Box$ (d) silver nitrate	
	(c) KCuI <sub>2</sub>	$\square  \text{(d) } Cu_2I_2$		70.	Percentage of gold in 14 carat gold is:	
55	•	melting copper pyrites with c				
55.		[B.V.(Pun			(c) 40	
	(a) FeS + ZnS		C) 2000)	71.	Silver nitrate is usually supplied in coloured bottles becau	use
	(c) $CuS + FeS_2$	$\Box  (b) \ Cu_2b + Cu_3$			it is:	
56.	<del>-</del>	brass, bronze and german silv	1		(a) oxidised in air	
50.	(a) Cu	(b) Mg	VCI 13.		(b) decomposes in sunlight	
	(c) Al	$\Box  (b) \text{ Mg}$ $\Box  (d) \text{ Zn}$	<u> </u>		(c) explodes in sunlight	
57	* *	ves in excess of KCN to giv			(d) reacts with air in sunlight	
5,,	Copper surprime dissor		E. 2006]	72.	Verdigris is:	
	(a) [Cu(CN) <sub>4</sub> ] <sup>3</sup> -	$\square  \text{(b) } [\text{Cu(CN)}_4]^{2-}$			(a) basic copper acetate $\Box$ (b) basic lead acetate	
	(c) Cu(CN) <sub>2</sub>	(d) CuCN			(c) basic lead	
58.	· · · · · · · · · · · · · · · · · · ·	per sulphate, the metal used to	recover	73.	In solid copper sulphate, copper is coordinated to:	
	copper, is:	•			(a) five water molecules $\Box$ (b) four water molecules	
	(a) Na	□ (b) Ag			(c) one sulphate ion $\Box$ (d) one water molecule	
	(c) Hg	☐ (d) Fe		74.	While extracting an element from its ore, the ore is grou	
59.	Argentite is an ore of:				and reacted with dilute KCN solution to form a solu	ıble
	(a) Ag	□ (b) Au			complex. The element is:	
	(c) Pt	□ (d) Cu			(a) lead	
60.	Cyanide process is use			75	(c) manganese	
	(a) Cr	□ (b) Ag		13.	Percentage of silver in the alloy german silver, is:	
	(c) Cu	$\Box$ (d) Zn			(a) 2.5%	
61.	On heating $Cu(NO_3)_2$ s	strongly, the material finally	obtained	76	(c) 10%	ш
	is:			/0.	(a) red lead	
	(a) Cu	☐ (b) Cu <sub>2</sub> O			(b) ammonical silver nitrate	
(0	(c) Cu(NO <sub>2</sub> ) <sub>2</sub>	$\square$ (d) Cu(NO <sub>3</sub> ) <sub>2</sub>		,	(c) ammonical AgNO <sub>3</sub> + red lead	
62.	•	ed to copper sulphate solution	on, blue		(d) ammonical AgNO <sub>3</sub> + red lead + HCHO	$\overline{\Box}$
	colour is obtained due	*	_	77.		ium
	(a) Cu <sup>2+</sup>	$\Box$ (b) Cu(NH <sub>4</sub> SO <sub>4</sub> ) <sub>2</sub>		'''	thiosulphate solution (hypo solution) is added to sil	
	(c) $[Cu(NH_3)_4]^{2+}$	$\Box$ (d) Cu(OH) <sub>2</sub>			bromide is: [E.A.M.C.E.T. 20	
63.	An alloy which does r				(a) $Ag_2S_2O_3$ $\square$ (b) $Ag_2S$	
	(a) solder	☐ (b) bell metal				
	(c) bronze	☐ (d) brass		70	(c) $Ag_3[Na(S_2O_3)_2]$	
64.				78.	German silver has: [D.C.E. 20	
	(a) AgNO <sub>3</sub>	$\Box  \text{(b) } \text{Cu}_2\text{Cl}_2$			(a) Zn	님
سدر	(c) CuCl <sub>2</sub>	(d) Hg <sub>2</sub> Cl <sub>2</sub>		70	(c) Ni	. 🗆
65.	Hair dyes contain:	[V.I.T.E.E		79.	, 11	_
	(a) copper nitrate	☐ (b) gold chloride			(a) CuO	
	(c) silver nitrate	$\Box$ (d) copper sulphate		1	(c) $Cu_2O_2$	لـــا

00	C'1 ' C' 11 11		erest.		1 0=				
80.	Silver is refined by cupell	ation p	rocess. The process rem	oves	95.	The liquid metal at room		•	
	the impurity of:		L. \ A	_		(a) Ca		(b) Zn	
	(a) Cu		b) Au		06	(c) Hg		(d) Pb	
	(c) Pb		d) Pt		96.	Cinnabar is the ore of:		d) <b>d</b> 1	<del></del>
81.	Which is least soluble in					(a) Zn		(b) Cd	
	(a) AgCl		b) AgBr		07	(c) Hg		(d) Ag	
	(c) AgI		d) Ag <sub>2</sub> S		97.	Chemically philosopher's			
82.	The compound soluble in			,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,		(a) ZnO		(b) BaO	
	(a) Cu(OH) <sub>2</sub>		b) Al(OH) <sub>3</sub>		00	(c) HgCl		(d) Hg <sub>2</sub> Cl <sub>2</sub>	. 🗆
	(c) Cr(OH) <sub>3</sub>		d) Fe(OH) <sub>3</sub>		98.	Philosopher's wool wher	nea	ted with BaO at 1100°C	gives
83.	AgCl on fusion with sod					the compound:		(L) D . (7.0)	
	(a) $Ag_2CO_3$		b) Ag <sub>2</sub> O		-	(a) BaCdO <sub>2</sub>		(b) Ba + $ZnO_2$	
	(c) Ag		d) $Ag_2C_2$		00	• •		(d) BaZnO <sub>2</sub>	
84.	Which metallurgy involv	es leac	ching? [D.C.E. 2	2006]	99.	The purest zinc is made		a) 16 th	_
	(a) Au		b) Ag			(a) Zone refining		(b) Mond's process	
	(c) both (a) and (b)	, D (	d) none of these		100	(c) Poling process			
85.	Gold is soluble in:	v			100.	A compound is yellow w	nen	not and white when cold	. The
	(a) conc. HCl		b) conc. H <sub>2</sub> SO <sub>4</sub>			compound is:		43 PLO	-
	(c) conc. HNO <sub>3</sub>		d) aqua-regia			(a) $Al_2O_3$		(b) PbO	
86.	Amongst the following, to	he low	est degree of paramagne	etism	101	(c) CaO		(d) ZnO	
	per mole of the compour	ıd will	be shown by:		101.	The hydroxide which is s	solub	ie in excess of NaOH soi	ution
	(a) MnSO <sub>4</sub> ·4H <sub>2</sub> O		b) CuSO <sub>4</sub> ·5H <sub>2</sub> O			is:		do recorn	-
	(c) FeSO <sub>4</sub> ·7H <sub>2</sub> O	<u> </u>	d) NiSO <sub>4</sub> ·6H <sub>2</sub> O			(a) Cu(OH) <sub>2</sub>		(b) Fe(OH) <sub>3</sub>	
87.	Identify the statement wh	ich is 1	not correct regarding Cu	SO <sub>4</sub> .	100	(c) Cr(OH) <sub>3</sub>		(d) $Zn(OH)_2$	
	(a) It reacts with KI to g	ive iod	line		102.	The colour of zinc sulph			-
	(b) It reacts with NaOH	and gl	ucose to give Cu2O	. 🗆		(a) yellow		(b) white	
	(c) It reacts with KCl to	_			100	(c) brown		· /	
	(d) It gives CuO on stro				103.	The compound which is	wic	iery used as a write pig	ment,
88.	What is the effect of sh			small		is:	_	(h) A1 ()	
	quantity of anhydrous C					(a) PbCO <sub>3</sub>		(b) $Al_2O_3$	
	(a) The white solid dissol	-		on 🗆	101	(c) ZnO		(d) CaCO <sub>3</sub>	
	(b) The white solid disso				104.	Corrosive sublimate is:			
	(c) The white solid disso					(a) HgCl <sub>2</sub>		(b) $Hg_2Cl_2$	
	(d) The white solid turn					(c) Hg <sub>2</sub> Cl		(d) $Hg_2Cl_3$	
89.	When copper reacts with				105.	Calomel is the name of:

## **Objective Questions for IIT ASPIRANTS**

- + Xe<sup>-</sup> Alkaline medium  $\rightarrow$  MnO<sub>4</sub><sup>2</sup>  $MnO_4$ +Ye Acidic medium +Ze Neutral medium
  - X, Y and Z are respectively:
  - (a) 1, 2, 3
- (c) 1, 3, 5
- (d) 5, 3, 1

[Hint: 
$$MnO_4^- + e^- \xrightarrow{Alk. \text{ med.}} MnO_4^{2-}$$

$$MnO_4^- + 8H^+ + 5e^- \xrightarrow{Acid. med.} Mn^{2+} + 4H_2O$$
  
 $MnO_4^- + 4H_2O + 3e^- \xrightarrow{Neu. med.} Mn^{4+} + 8OH^-$ 

- A metal M which is not affected by strong acids like conc. HNO<sub>3</sub>, conc. H<sub>2</sub>SO<sub>4</sub> and concentrated solutions of alkalies like KOH and NaOH but dissolves in aqua-regia and forms  $MCl_3$  which is used for toning in photography. The metal M is:
  - (a) Ag

(b) Hg

(c) Au

(d) Cu

[Hint: Au is not affected by concentrated acids and strong alkalies. However, it dissolves in aqua-regia forming AuCl<sub>3</sub> which is used for toning in photography.

$$[HNO_3 + 3HCl \longrightarrow NOCl + 2Cl + 2H_2O] \times 3$$

$$[Au + 3Cl \longrightarrow AuCl_3] \times 2$$

$$2Au + 3HNO_3 + 9HCl \longrightarrow 2AuCl_3 + 3NOCl + 6H_2O$$

- The metals present in insulin, haemoglobin and vitamin B<sub>12</sub> are respectively:
  - (a) Zn, Hg, Cr
- (b) Co, Fe, Zn
- (c) Mg, Fe, Co
- (d) Zn, Fe, Co

[Hint: Insulin contains zinc, haemoglobin contains iron and vitamin B<sub>12</sub> contains cobalt.]

- Zinc gives H<sub>2</sub> gas with H<sub>2</sub>SO<sub>4</sub> and conc. HCl but not with conc. HNO3 because:
  - (a) NO<sub>3</sub> ion is reduced in preference to hydronium ion
  - (b) conc. HNO<sub>3</sub> is a weaker acid than conc. H<sub>2</sub>SO<sub>4</sub> and conc.
  - (c) conc. HNO3 acts as a reducing agent
  - (d) zinc is more reactive than H<sub>2</sub>

[Hint: 
$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2 \uparrow$$
  
 $Conc.$ 

$$Zn + 2HCl \longrightarrow ZnCl_2 + H_2 \uparrow$$

$$Zn + 4HNO_3 \longrightarrow Zn(NO_3)_2 + 2NO_2 \uparrow + 2H_2O$$

$$Conc.$$

NO<sub>3</sub> ion is reduced to NO<sub>2</sub> in preference to H<sub>3</sub>O<sup>+</sup> ion.]

- 'Bordeaux mixture' is used as a fungicide. Its composition
  - (a)  $CaSO_4 + Cu(OH)_2$
- (b)  $CuSO_4 + Ca(OH)_2$
- (c)  $CuSO_4 + CaO$
- (d) CuO + CaO
- A compound of mercury used in cosmetics, in Ayurvedic and Yunani medicines and known as Vermilion is:
  - (a) HgCl<sub>2</sub>
- (b) Hg<sub>2</sub>Cl<sub>2</sub>

(c) HgS

(d) HgI<sub>2</sub>

- 7. An ornament of gold having 87.5% of gold, is of ..... carat.
  - (a) 21
- (b) 18
- (c) 15
- (d) 24

[Hint: Pure gold = 24 carat

$$87.5\% \text{ gold} = \frac{87.5}{100} \times 24 = 21.0 \text{ car at}$$

- 87.5% gold =  $\frac{87.5}{100} \times 24 = 21.0$  carat ] The highest magnetic moment is shown by the transition metal ion with outer electronic configuration:
  - (a)  $3d^2$

(c)  $3d^9$ 

(d)  $3d^5$ 

[Hint: In  $3d^5$  configuration, all the d-orbitals are singly occupied, i.e., it has maximum number of unpaired electrons.]

- Number of moles of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> reduced by one mole of Sn<sup>2+</sup> ions is:
  - (a) 1/3

(c) 1/6

(d) 6

[Hint:  $Cr_2O_7^{2-} + 3Sn^{2+} + 14H^+ \longrightarrow 2Cr^{3+} + 3Sn^{4+} + 7H_2O$ 3 moles of  $\operatorname{Sn}^{2+}$  ions reduce = 1 mole of  $\operatorname{Cr}_2\operatorname{O}_7^{2-}$ 

= 1 mole of  $K_2Cr_2O_7$ 

1 mole of  $Sn^{2+}$  ions will reduce = 1/3 mole of  $K_2Cr_2O_7$ 

- 10. The reason for the stability of Gd<sup>3+</sup> ion is:
  - (a) 4f-subshell completely filled
  - (b) 4f-subshell empty
  - (c) 4f-subshell half filled
  - (d) possesses the configuration of a noble gas
- 11. Which is the first man-made element?
  - (a) Sc

(b) Tc

(c) Os

- (d) Zr
- **12.** Select correct statement:
  - (a) PH<sub>3</sub> reduces AgNO<sub>3</sub> to metallic Ag
  - (b) Organic tissues turn AgNO3 black by reducing it to Ag
  - (c) AgCN is soluble in KCN
  - (d) All are correct statements
- 13. When K<sub>2</sub>CrO<sub>4</sub> is added to CuSO<sub>4</sub> solution, there is formation of CuCrO<sub>4</sub> as well as CuCr<sub>2</sub>O<sub>7</sub>. Formation of CuCr<sub>2</sub>O<sub>7</sub> is due
  - (a) basic nature of CuSO<sub>4</sub> solution
  - (b) acidic nature of CuSO₄ solution
  - (c) this is the typical property of CuSO<sub>4</sub>
  - (d) there is no formation of CuCr<sub>2</sub>O<sub>7</sub>
- 14. In K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, every Cr is linked to:
  - (a) two O-atoms
- (b) three O-atoms
- (c) four O-atoms
- (d) five O-atoms

**[Hint:** The structure of  $Cr_2O_7^{2-}$  ion is,

- 15. A blue solution of copper sulphate becomes darker when treated with excess of ammonia. This is because:
  - (a) ammonia molecules replace water molecules in the solution
  - (b) ammonia is stronger ligand than water

- (c) ammonia forms a stable complex ion [Cu(NH<sub>1</sub>)<sub>4</sub>]<sup>2+</sup> with Cu<sup>2+</sup> ions
- (d) All are correct

[Hint:

$$\begin{array}{ll} [Cu(H_2O)_4]SO_4 \cdot H_2O + 4NH_4OH & \longrightarrow [Cu(NH_3)_4]SO_4 + 9H_2O] \\ \text{Blue soln.} \end{array}$$

- 16. Sugar in urine-sample can be detected by:

  - (a) Fehling's solution (b) Benedict's solution
  - (c) Tollen's reagent
- (d) all the three (a), (b) and (c)

[Hint: Fehling's soln.—Cu(II) ion (complexed with tartrate ion) is heated in basic solution with a reducing sugar, brick red precipitate of Cu<sub>2</sub>O is formed. Mixture of alk. CuSO<sub>4</sub> and sodium potassium tartrate is called Fehling's solution.

> Benedict's soln.—It contains Cu(II) ion complexed to citrate ion. When it is heated with reducing sugar, Cu(II) is reduced to Cu<sub>2</sub>O.

> Tollen's reagent—Ammonical AgNO3 solution is called Tollen's reagent. Reducing sugars give silver mirror test with Tollen's reagent.

17. In the process of extraction of gold,

Roasted gold ore + 
$$\operatorname{CN}^- + \operatorname{H}_2\operatorname{O} \xrightarrow{\operatorname{O}_2} [X] + \operatorname{OH}^-$$
  
 $[X] + \operatorname{Zn} \longrightarrow [Y] + \operatorname{Au}$ 

Identify the complexes [X] and [Y]:

(a) 
$$X = [Au(CN)_2]^-$$
,  $Y = [Zn(CN)_4]^{2-}$   
(b)  $X = [Au(CN)_4]^3-$ ,  $Y = [Zn(CN)_4]^{2-}$ 

(b) 
$$X = [Au(CN)_4]^{3-}$$
,  $Y = [Zn(CN)_4]^2$ 

(c) 
$$X = [Au(CN)_2]^T$$
,  $Y = [Zn(CN)_6]^4$ 

(c) 
$$X = [Au(CN)_2]^-$$
,  $Y = [Zn(CN)_6]^4$   
(d)  $X = [Au(CN)_4]^{3^-}$ ,  $Y = [Zn(CN)_4]^{2^-}$ 

[Hint: 
$$2Au + 4CN^{-} + H_2O + \frac{1}{2}O_2 \longrightarrow 2[Au(CN)_2]^{-} + 2OH^{-}$$

$$2[Au(CN)_2]^{-} + Zn \longrightarrow [Zn(CN)_4]^{2-} + 2Au]$$

- 18. A metal gives two chlorides 'A' and 'B'. 'A' gives black precipitate with NH4OH and 'B' gives white. With KI 'B' gives a red precipitate soluble in excess of KI. 'A' and 'B' are respectively:
  - (a) HgCl<sub>2</sub> and Hg<sub>2</sub>Cl<sub>2</sub>
- (b) Hg<sub>2</sub>Cl<sub>2</sub>, HgCl<sub>2</sub>
- (c) HgCl<sub>2</sub> and HgCl
- (d) none of these

[Hint: 'A' is Hg<sub>2</sub>Cl<sub>2</sub> and 'B' is HgCl<sub>2</sub>.

- **19.** An inorganic compound (A) gave the following reactions:
  - (i) The compound on heating gave a residue and a gaseous mixture of NO2 and O2.

(ii) The aqueous solution of (A) gave a white precipitate with sodium chloride solution. The precipitate dissolves in NH₄OH.

The compound (A) is:

- (a)  $Pb(NO_3)_2$
- (b) Ba(NO<sub>3</sub>)<sub>2</sub>
- (c) AgNO<sub>3</sub>
- (d) none of these

 $2AgNO_3 \longrightarrow 2Ag + 2NO_2 + O_2$ [Hint:

The inorganic compound may be:

$$AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$$

$$AgNO_3 + NaCI \longrightarrow AgCI + NaNO_3$$
  
 $AgCI + 2NH_4OH \longrightarrow Ag(NH_3)_2CI + 2H_2O]$ 

- 20. An inorganic compound on strong heating gave a blackish brown powder and two oxides of sulphur. The powder was dissolved in HCl when a yellow solution was obtained which gave a blood red coloured solution with thiocyanide ions.
  - (a) CuSO<sub>4</sub>
- (b) ZnSO<sub>4</sub>

- (c) NiSO<sub>4</sub> (d) FeSO<sub>4</sub>

$$Fe_2O_3 + 6HCl \longrightarrow 2FeCl_3 + 3H_2O$$
Yellow

[Hint:  $2FeSO_4 \longrightarrow Fe_2O_3 + SO_2 + SO_3$ 

FeCl<sub>3</sub> + CNS<sup>-</sup> 
$$\longrightarrow$$
 Fe(CNS)<sub>3</sub> + 3Cl<sup>-</sup> ]

Blood red

- 21. When K<sub>2</sub>CrO<sub>4</sub> is added to CuSO<sub>4</sub> solution, there is formation of CuCrO<sub>4</sub> and CuCr<sub>2</sub>O<sub>7</sub>. Formation of CuCr<sub>2</sub>O<sub>7</sub> is due to :
  - (a) basic nature of CuSO<sub>4</sub> solution which converts CrO<sub>4</sub><sup>2-</sup> to Cr<sub>2</sub>O<sub>7</sub><sup>2-</sup>
  - (b) acidic nature of CuSO<sub>4</sub> solution which converts CrO<sub>4</sub><sup>2</sup> to  $Cr_2O_7^{2-}$
  - (c) CuSO<sub>4</sub> has a typical property of converting CrO<sub>4</sub><sup>2-</sup> to  $Cr_2O_7^2$
  - (d) none of the above is correct
- 22. More number of oxidation states are exhibited by the actinoids than by the lanthanoids. The main reason for this is:

[A.I.E.E.E. 2008]

- (a) greater metallic character of the lanthanides than that of the corresponding actinides
- (b) lesser energy difference between 5f and 6d-orbitals than that between 4f and 5d-orbitals
- (c) more active nature of actinoids
- (d) more energy difference between 5f and 6d-orbitals than that between 4f and 5d-orbitals
- 23. Among the following transition elements, pick out the element(s) with highest second ionisation energy:
  - (i) V(Z=23) (ii) Cr(Z=24) (iii) Mn(Z=25) (iv) Cu(Z=29)
  - (v) Zn(Z = 30)
  - (a) (i) and (iii)
- (b) (ii) and (iv)
- (c) (ii) and (v)
- (d) (iv) only

[Hint: Cu<sup>+</sup> has stable configuration, [Ar]3d<sup>10</sup>.]

#### tuswers 1. (b) 2. (c) 3. (d) 4. (a) 5. (b) 6. (c) 7. (a) 8. (d) 9. (a) **10.** (c) **11.** (b) 12. (d) 13. (b) 15. (d) 16. (d) **19.** (c) 14. (c) 17. (a) 18. (b) 20. (d) 21. (b) 22. (b) 23. (d)

## Matrix Matching Questions for IIT Aspirants

1.	Match the Column-I with	n Column-II:	7.	Match the ions of List-I with	h their characteristics in List-II:

## **Assertion-Reason Type Questions**

Following questions consist of an Assertion (A) and Reason (R). Use the following key to choose the correct answer:

- (a) If both (A) and (R) are correct and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are correct but (R) is not the correct explanation of (A).
- (c) If (A) is correct but (R) is incorrect.
- (d) If (A) is incorrect but (R) is correct.
- 1. (A) Tungsten has a very high melting point.
  - (R) Tungsten is a covalent compound. [A.I.I.M.S. 1997]
- 2. (A) Mn-atom loses ns electrons first during ionisation as compared to (n-1)d electrons.
  - (R) The effective nuclear charge experienced by (n-1)d electrons is greater than that by ns electrons.

[A.I.I.M.S. 2001]

- 3. (A) KMnO<sub>4</sub> is a coloured compound.
  - (R) Colour of KMnO<sub>4</sub> is due to charge transfer.
- 4. (A) TiCl<sub>4</sub> is a colourless compound.
  - (R) Ti<sup>4+</sup> ion has no unpaired electron.
- (A) KMnO<sub>4</sub> is oxidising agent in neutral, acidic and in basic medium.
  - (R) Equivalent mass of KMnO<sub>4</sub> in acidic medium is 31.6.

- **6.** (A)  $K_2CrO_4$  is yellow coloured compound.
  - (R) Chromate ion has tetrahedral geometry.
- 7. (A) Solution of Na<sub>2</sub>CrO<sub>4</sub> in water is intensely coloured.
  - (R) Oxidation state of Cr in Na<sub>2</sub>CrO<sub>4</sub> is (+VI).

[A.I.I.M.S. 2003]

- **8.** (A) All the members of actinide series are radioactive in nature.
  - (R) The electrons are gradually accommodated in 5f-energy subshell.
- 9. (A) The spin only magnetic moment of  $Sc^{3+}$  is 1.73 B.M.
  - (R) The spin only magnetic moment of an ion is equal to  $\sqrt{n(n+2)}$ ; where *n* is the number of unpaired electrons in the ion.
- **10.** (A) Potassium ferrocyanide is diamagnetic whereas potassium ferricyanide is paramagnetic.
  - (R) Crystal field splitting in ferrocyanide ion is greater than that of ferricyanide ion.
- 11. (A) The free gaseous Cr-atom has six unpaired electrons.
  - (R) Half filled s-orbital has greater stability.
- 12. (A) Ionisation of transition metals involve loss of ns electrons before (n-1)d electrons.
  - (R) Filling of *ns*-orbitals take place before the filling of (n-1)d-orbitals.

11. (c) 12. (b)

## THOUGHT TYPE QUESTIONS

Two types of magnetic behaviour are found in substances:
(a) Diamagnetism and (b) Paramagnetism

Diamagnetic substances are those which are repelled by an applied magnetic field. Such substances have no unpaired electron. Paramagnetic substances are those which are attracted by an applied magnetic field. Transition metals and many of their compounds show paramagnetic behaviour where there are unpaired electron or electrons. The magnetic moment arise from the spin and orbital motions in ions or molecules. Magnetic moment of n unpaired electrons is given as,

$$\mu = \sqrt{n(n+2)}$$
 Bohr Magneton

Magnetic moment increases as the number of unpaired electrons increases.

- 1. In 3d series, the maximum magnetic moment is shown by:
  - (a) Sc (At. no. 21)

(b) V(23)

(c) Cr (24)

(d) Fe (26)

[Hint: Cr-atom has maximum number of unpaired electrons, i.e., 6. Hence, the magnetic moment =  $\sqrt{6 \times 8} = \sqrt{48}$  B.M.]

2. Which among the following ions has maximum value of magnetic moment?

(a)  $Cu^{2+}$ 

(b) Mn<sup>24</sup>

(c) Cr<sup>2+</sup>

(d)  $Ti^{24}$ 

[Hint: 
$$Cu^{2+}$$
 E.C. = 2, 8, 8 + 9,  $\mu = \sqrt{3}$  B.M.; 
$$Mn^{2+}$$
 E.C. = 2, 8, 8 + 5,  $\mu = \sqrt{35}$  B.M.; 
$$Cr^{2+}$$
 E.C. = 2, 8, 8 + 4,  $\mu = \sqrt{24}$  B.M.; 
$$Ti^{2+}$$
 E.C. = 2, 8, 8 + 2,  $\mu = \sqrt{8}$  B.M.]

3. Increasing value of magnetic moments of (I)  $[Fe(CN)_6]^{4-}$ , (II)  $[Fe(CN)_6]^{3-}$ , (III)  $[Cr(NH_3)_6]^{3+}$ , (IV)  $[Ni(H_2O)_4]^{2+}$  is:

- (a) I < II < III < IV
- (b) IV < III < II < I
- (c) II < III < I < IV
- (d) I < II < IV < III

[Hint:  $[Fe(CN)_6]^4$  unpaired electron = 0;  $[Fe(CN)_6]^{3-}$  unpaired electron = 1;  $[Cr(NH_3)_6]^{3+}$  unpaired electron = 3;

 $[Ni(H_2O)_4]^{2+}$  unpaired electron = 2]

- 4. Magnetic moment of [Ni(CN)<sub>4</sub>]<sup>2-</sup> is zero but that of  $[Ni(H_2O)_4]^{2+}$  is 2.83 B.M. It is because of:
  - (a) CN is a strong ligand making two unpaired electrons in  $Ni^{2+}$  to pair up, while in  $[Ni(H_2O)_4]^{2+}$  two electrons remain unpaired as H2O is a weak ligand
  - (b) different oxidation state of Ni in two complexes
  - (c) both (a) and (b)
  - (d) none of the above
- 5. Magnetic moments of Cr (Z = 24), Mn<sup>+</sup> (Z = 25) and Fe<sup>2+</sup> (Z = 26) are x, y and z respectively. Which of the following order is correct?
  - (a) x < y < z
- (b) x = y < z
- (c) z < x = y
- (d) x = y = z

**Hint**:  $x = \sqrt{48}$ ;  $y = \sqrt{48}$ ;  $z = \sqrt{24}$ 

Cr = 6 unpaired electrons,  $Mn^+ = 6$  unpaired electrons.  $Fe^{2+} = 4$  unpaired electrons.

- 6. There are three unpaired electrons in  $[Co(H_2O)_6]^{2+}$  and calculated value of magnetic moment on the basis of  $\sqrt{n(n+2)}$  formula is 3.87 B.M. which is lower than the experimental value of 4.40 B.M. The reason for this difference is due to:
  - (a) increase in number of unpaired electrons during determination
  - (b) some contribution of the orbital motion of the electrons to the magnetic moment
  - (c) d-d transition
  - (d) experimental error

## THOUGHT 2

Most of the compounds of the transition metals are coloured in the solid or in solution states. The colour of the transition metal ions arises from the excitation of electrons from the d-orbitals of lower energy to the d-orbitals of higher energy. The energy required for d-d electron excitation is available in the visible range. Transition metal ions have the tendency to absorb certain radiations from the visible region and exhibit the complementary colour.

The transition metal ions which have completely filled d-orbitals are colourless as the excitation of electron or electrons is not possible within d-orbitals. The transition metal ions which have completely empty d-orbitals are also colourless. In certain oxysalts of transition elements like KMnO<sub>4</sub>, K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, there are no unpaired electrons at the central atom but they are deep in colour. The colour of these compounds is due to charge transfer spectrum. For example, in MnO<sub>4</sub>, an electron is momentarily transferred from O to the metal and thus oxygen changes from  $O^{2-}$  to  $O^{-}$  and manganese from Mn(+VII) to Mn(+VI).

- 1. Select the correct statement:
  - (a) Colour of the transition metal ion arises due to d-d transition
  - (b) Colour of certain oxysalts of transition metals is due to charge transfer
  - (c) Both are correct
  - (d) None is correct
- Which of the following is paramagnetic as well as coloured ion?
  - (a) Cu<sup>+</sup>

(b) Cu<sup>2+</sup>

(c)  $Sc^{3+}$ 

- (d)  $Zn^{2+}$
- **3.** Which is a coloured ion?
  - (a)  $[Cr(H_2O)_6]^{3+}$
- (c)  $[Ti(H_2O)_6]^{4+}$
- (b) [Cu(CN)<sub>4</sub>]<sup>3-</sup> (d) [Sc(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup>
- 4. K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> gives coloured solution in water. The colour is due
  - (a) d-d transition in Cr-atoms
  - (b) presence of unpaired electron in d-orbital in oxygen
  - (c) charge transfer from O to Cr
  - (d) none of the above
- 5. Which of the following compounds is (are) coloured due to charge transfer spectra and not due to d-d transitions?
  - (a) KMnO<sub>4</sub>
- (b) K2CrO4

(c) CrO<sub>3</sub>

(d) all of these

## THOUGHT 3

Photography is based on the nature of silver halides. Except AgF, the silver halides are photosensitive. These undergo decomposition in light and turn black due to formation of free silver.

$$2AgBr \xrightarrow{Light} 2Ag + Br_2$$

The photographic plates or films are prepared in a dark and dustfree room by applying a light sensitive mixture called emulsion which is prepared by adding 20 per cent aqueous solution of silver nitrate to ammonium bromide solution containing gelatin.

When such a film is exposed, the emulsion gets affected. Since different parts of the body reflect light of varied intensity, the film or plate is affected proportionately. An actual but inverted image of the object is thus formed on the film or plate which is not visible to the eye. It is, therefore, called the latent image.

When this exposed film or plate is dipped in a developer which contains a reducing agent, the parts affected most during exposure are reduced to the maximum. The image becomes visible. It is called a negative. The remaining sensitive emulsion on the negative is removed by dissolving it in hypo solution (fixer). Finally, a positive of the negative already prepared is made on silver bromide paper.

- The compound formed on the unexposed photographic film or plate is:
  - (a) silver nitrate
- (b) ammonium bromide
- (c) diamminesilver bromide (d) silver bromide
- The exposed part of the film or plate after developing contains:

- (a) silver metal
- (b) silver oxide
- (c) silver bromide
- (d) silver nitrate
- 3. The solution of the developer consists:
  - (a) alkaline solution of pyrogallol
  - (b) alkaline solution of quinol
  - (c) either (a) or (b)
  - (d) neither (a) nor (b)
- 4. Silver halides are used in photography because these compounds:
  - (a) are insoluble in water
- (b) are affected by light
- (c) are soluble in ammonia solution
- (d) easily stick on the surface of photographic plate or film
- 5. Silver bromide dissolves in hypo solution forming:
  - (a)  $Ag_2S_2O_3$
- (b) Ag<sub>2</sub>S
- (c)  $Na_3[Ag(S_2O_3)_2]$
- (d) NaAgS<sub>2</sub>O<sub>3</sub>

#### THOUGHT 4

The process of corrosion of iron is known as rusting. Rust appears to be a hydrated ferric oxide, Fe<sub>2</sub>O<sub>3</sub>·xH<sub>2</sub>O. Both O<sub>2</sub> and H<sub>2</sub>O are required for rusting. Iron can be protected from the rusting by use of following methods:

- (i) Applying paints, lacquers and enamels on the surface of iron.
- (ii) By forming a firm and coherent protective coating of ferrosoferric oxide. This is done by passing steam over hot iron.
- (iii) By coating a thin film of zinc, tin, nickel, chromium, aluminium, etc., on the surface of iron.

If plated with zinc, the reaction products of zinc with O2 and H<sub>2</sub>O form a coating which sticks to the surface and thereby protects iron.

- 1. Rusting is a corrosion process in which:
  - (a) Zn reacts with O2
  - (b) Sn reacts with O2 and H2O
  - (c) Fe is converted into hydrated ferric oxide
  - (d) minute holes are formed on the surface of a metal
- Zinc protects iron from corrosion because:
  - (a) it is an active metal
  - (b) a sticky coating is formed on its surface on exposure to
  - (c) it is not affected by atmosphere
  - (d) it has lower oxidation potential than iron

- 3. Galvanisation means:
  - (a) deposition of Zn on Fe
  - (b) deposition of Al on Fe
  - (c) deposition of Sn on Fe
  - (d), deposition of Cu on Fe
- 4. Corrosion is an electrochemical process. It involves:
  - (a) loss of electrons by iron, Fe  $\longrightarrow$  Fe<sup>2+</sup> + 2e, i.e., iron acts as an anode.
  - (b) impurities act as a cathode. Electrons are used in forming hydroxyl ions.

$$H_2O + O + 2e \longrightarrow 2OH$$

(c) ferrous ions are oxidised to ferric ions in presence of dissolved oxygen.

$$2Fe^{2+} + O + H_2O \longrightarrow 2Fe^{3+} + 2OH^{-}$$

- (d) all the above reactions
- 5. For prevention of rusting of iron, which is used in paints?
  - (a) PbO

- (b) PbO<sub>2</sub>
- (c) Pb<sub>3</sub>O<sub>4</sub>
- (d) PbSO<sub>4</sub>

#### **THOUGHT 5**

Copper is the most noble of the first row transition metals and occurs in small deposits in several countries. Ores of copper include chalcanthite (CuSO<sub>4</sub>·5H<sub>2</sub>O), atacamite [Cu<sub>2</sub>Cl(OH)<sub>3</sub>], Cuprite (Cu2O), copper glance (Cu2S) and malachite [Cu<sub>2</sub>(OH)<sub>2</sub>CO<sub>3</sub>]. However, 80% of the world's copper production comes from the ore chalcopyrite (CuFeS2). The extraction of copper from chalcopyrite involves partial roasting, removal of iron and [I.I.T. 2010] self reduction.

- 1. Partial roasting of chalcopyrite produces:
  - (a) Cu<sub>2</sub>S and FeO
- (b) Cu<sub>2</sub>O and FeO
- (c) CuS and Fe<sub>2</sub>O<sub>3</sub>
- (d) Cu<sub>2</sub>O and Fe<sub>2</sub>O<sub>3</sub>
- 2. Iron is removed from chalcopyrite as:
  - (a) FeO

- (b) FeS
- (c) Fe<sub>2</sub>O<sub>3</sub>
- (d) FeSiO<sub>3</sub>
- 3. In self reduction, the reducing species is:

(b)  $O^{2-}$ 

(c)  $S^{2-}$ 

(d)  $SO_2$ 

Thought 1 Thought 4 1, (c) 2. (b) 3. (d) **4.** (a) 5. (c) **6.** (b) 5. (c) **1.** (c) **2.** (b) 3. (a) **4.** (d) Thought 2 1. (c) 2. (b) 3. (a) **4.** (c) 5. (d) Thought 5 1. (b) 2. (d) 3. (c)

#### BRAIN STORMING PROBLEMS

1. Explain, why Mn<sup>3+</sup> is less stable than Mn<sup>2+</sup> and Mn<sup>4+</sup> ions?

Explain, why Mn<sup>3+</sup> disproportionate into Mn<sup>2+</sup> and Mn<sup>4+</sup>

 $Mn^{3+} \longrightarrow 3d^4, 4s^0$   $Mn^{4+} \longrightarrow 3d^3, 4s^0$ [Ans.  $Mn_{25} \longrightarrow 3d^5, 4s^2;$   $Mn^{2+} \longrightarrow 3d^5, 4s^0;$ 

On the basis of electronic configuration, Mn<sup>2+</sup> and Mn<sup>4+</sup> are expected to be more stable, hence, Mn<sup>3+</sup> undergoes disproportionation.

 $2Mn^{3+} \longrightarrow Mn^{2+} + Mn^{4+}$ 

2. Standard reduction potential of copper is greater than that of hydrogen vet it liberates hydrogen from a concentrated solution of hydrochloric acid. Explain this fact with proper reasoning.

 $Cu^{2+} + 2e \longrightarrow Cu(s)$ ;  $E^{\circ}_{\text{Cu}^{2+}/\text{Cu}} = +0.34 \text{ volt}$  $2H^{+}+2e\longrightarrow H_{2}(g)$ ;  $E^{\circ}_{H^{+}/H_{2}} = 0.00 \text{ volt}$ 

[Ans. When copper is treated with conc. HCl then formation of stable complex ion [CuCl<sub>4</sub>]<sup>2-</sup> along with liberation of H<sub>2</sub> gas takes place.

 $Cu + 4HCl(conc.) \longrightarrow [CuCl_4]^{2-} + 2H^+ + H_2^{\uparrow}$ 

- 3. Account for the following facts:
  - (a) An aqueous solution of FeCl<sub>3</sub> is slightly yellowish in
  - (b) Cu(I) compounds are not known in aqueous solution. [Ans.
    - (a) An aqueous solution of FeCl<sub>3</sub> is colloidal. It is yellowish in colour due to Tyndall effect.
    - (b) Cu(I) compounds undergo disproportionation in aqueous medium.

$$Cu_2Cl_2 \longrightarrow CuCl_2 + Cu]$$

- 4. Answer the following questions:
  - (a) Which is more basic?

(i) ZrO<sub>2</sub> or TiO<sub>2</sub>

(ii)  $V_2O_5$  or  $Nb_2O_5$ 

(iii) OsO<sub>4</sub> or ReO<sub>2</sub>

- (b) Which is more stable  $[CoCl_6]^{3-}$  or  $[IrCl_6]^{3-}$ ?
- (c) Which forms trans isomer [PtCl<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>] or.  $[PtCl(NH_3)_3]^{\dagger}$ ?
- (d) Which is more oxidising agent Cr(VI) or Mo(VI)? Ans.
  - (a) (i) ZrO<sub>2</sub> (ii) Nb<sub>2</sub>O<sub>5</sub> (iii) ReO<sub>2</sub>
  - (b)  $[IrCl_6]^{3-}$  is more stable than  $[CoCl_6]^{3-}$  because in +3 state Ir is more stable than Co.
  - (c) [PtCl<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>] will form trans isomer.
  - (d) Cr(VI) is stronger oxidising agent than Mo(VI).]
- 5. Write down the names of crystal structures in which the following elements are present.

Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn

[Ans.	Element	Crystal Structure
	Sc	fcc
	Ti	hcp
	V	bcc
	Cr	bcc
	Mn	bcc, tet

Fe	bcc, fcc
· Co	fcc, hcp
Ni	fcc
Cu	fcc
Zn	hcp ]

- **6.** Write down the name of catalyst for the following:
  - (i) In the synthesis of hydrocarbon in Fischer-Tropsch process.
  - (ii) Adams catalyst in reduction.
  - (iii) Deacon's process of making Cl<sub>2</sub> from HCl.
  - (iv) Reppe synthesis of benzene.
  - (v) Fenton's reagent in the synthesis of aldehydes from alcohols.

[Ans. (i) Co/Fe (ii) Pt/PtO (iii) CuCl<sub>2</sub> (iv) Ni complexes (v) FeSO<sub>4</sub>/H<sub>2</sub>O<sub>2</sub> ---

7. (a) Calculate magnetic moment of  $Fe^{3+}$  in  $[Fe(CN)_6]^{3-}$  and in  $[Fe(H_2O)_6]^{3+}$ .

> [Hint: In [Fe(CN)<sub>6</sub>]<sup>3-</sup>, Fe<sup>3+</sup> ion has only one unpaired electron. Thus, magnetic moment of Fe<sup>3+</sup> will be  $\sqrt{3}$ , i.e., 1.732 B.M.  $(\mu_p = \sqrt{n(n+2)})$  B.M., where, n. is number of unpaired electrons). In [Fe(H<sub>2</sub>O)<sub>6</sub>]<sup>3+</sup>, Fe<sup>3+</sup> ion has 5 unpaired electrons, hence, its magnetic moment will be  $\sqrt{35}$  B.M., i.e., 5.92 B.M.]

(b) Arrange following complexes in decreasing order of magnetic moment:

 $[Ni(H_2O)_4]^{2+}$ ,  $[Ni(CN)_4]^{2-}$ ,  $[Fe(CN)_6]^{3-}$ ,  $[Fe(CN)_6]^{4-}$ 

 $[Fe(CN)_6]^{4-} = [Ni(CN)_4]^{2-} < [Fe(CN)_6]^{3-} <$  $[Ni(H_2O)_4]^{2+}]$ 

[Hint: In  $[Fe(CN)_6]^4$  and  $[Ni(CN)_4]^{2-}$ , central atom has no unpaired electron, hence, their magnetic moment is zero. In  $[\text{Fe}(\text{CN})_6]^{3-}$ , there is only one electron with central Fe<sup>3+</sup> ion, hence, its magnetic moment will be 1.732 B.M. In  $[Ni(H_2O)_4]^{2+}$ , there are two unpaired electrons with Ni<sup>2+</sup> and hence, its magnetic moment will be  $\sqrt{8}$  B.M.]

8. Give the formula of three ions which are coloured due to charge transfer spectra.

[Ans.  $VO_2^+$ ,  $CrO_4^{2-}$ ,  $MnO_4^-$ ]

[Hint: Oxidation state of Ion Colour central atom  $VO_2^+$ +5 pale yellow  $CrO_4^{2-}$ +6 dark yellow  $MnO_4$ +7 dark purple

- 9. What happens when?
  - (i) CO<sub>2</sub> gas is passed through aqueous solution of Na<sub>2</sub>CrO<sub>4</sub>.
  - (ii) Ammonium dichromate is heated strongly.
  - (iii) Two gases 'A' and 'B' turns acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> green. When these gases are passed through water simultaneously, solution turns turbid yellow. What are the gases 'A' and 'B'?

[Ans. (i) Sodium dichromate, Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is formed,

(ii) N<sub>2</sub> and Cr<sub>2</sub>O<sub>3</sub> are formed,

(iii) 'A' and 'B' are SO<sub>2</sub> and H<sub>2</sub>S.]

 $\textbf{[Hint: (i) } H_2O + CO_2 \longrightarrow H_2CO_3$ 

Carbonic acid

 $2Na_2CrO_4 + H_2CO_3 \longrightarrow Na_2CO_3 + Na_2Cr_2O_7 + H_2O_3$ 

(ii) 
$$(NH_4)_2Cr_2O_7 \xrightarrow{\Delta} N_2 + Cr_2O_3 + 4H_2O$$

(iii) 
$$K_2Cr_2O_7 + 4H_2SO_4 \rightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$

$$\{H_2S + [O] \longrightarrow H_2O + S\} \times 3$$

$$K_2Cr_2O_7 + 4H_2SO_4 + 3H_2S \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 3S$$

$$K_2Cr_2O_7 + H_2SO_4 + 3SO_2 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O$$
Green

When both SO<sub>2</sub> and H<sub>2</sub>S are passed simultaneously through water then colloidal sulphur is precipitated.

$$2H_2S + SO_2 \longrightarrow 2H_2O + 3S$$
 ]

Yellowish turbidity

## intigetar vanting mittelling

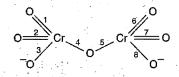

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. How many number of unpaired electrons are present in  $Mn^{2+}$ ?
- 2. What is the magnetic moment of Fe<sup>3+</sup>?
- 3. How many sigma bonds are present in  $Cr_2O_7^{2-}$  ion?
- **4.** How many electrons are involved in the reduction of KMnO<sub>4</sub> in acidic medium?
- 5. The change in the oxidation number of chromium in potassium dichromate when it acts as an oxidising agent is:
- **6.** How many water molecules are associated with a molecule of Mohr's salt?
- 7. When ammonium hydroxide is added to copper sulphate, a blue coloured complex is formed. What is the coordination number of copper in the complex?
- 8. The percentage of impurity in the 23 carat gold is:

### Answers

1. (5) The at. no. of Mn is 25. The number of electrons associated with  $Mn^{2+} = 23$ 

- 2. (6) The electronic configuration of Fe<sup>3+</sup> is : 2, 8, 8 +5. Mag. moment =  $\sqrt{5 \times 7} \approx 6$
- 3. (8) The structure of dichromate ion is

- 4. (5)  $MnO_4^- + 8H^+ + 5e^- \longrightarrow Mn^{2+} + 4H_2O$
- 5. (3)  $\operatorname{Cr}_2\operatorname{O}_7^{2-} \longrightarrow 2\operatorname{Cr}^{3+}$

Oxidation number of Cr in  $Cr_2O_7^{2-}$  is +6, change (6-3)=3

- 6. (6) The formula of Mohr's salt is: FeSO<sub>4</sub> (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> 6H<sub>2</sub>O
- 7. (4) The blue complex is, [Cu(NH<sub>3</sub>)<sub>4</sub>]SO<sub>4</sub>.
- **8.** (4) % Gold =  $\frac{100}{24} \times 23 = 96$

Impurities percentage (100 - 96) = 4

## CHAPTER 15

# Coordination Compounds and Organometallics

#### Contents:

- 15.1 Molecular or Addition Compounds
- 15.2 Terminology of Coordination Compounds
- 15.3 Nomenclature of Coordination Compounds
- 15.4 Werner's Coordination Theory
- 15.5 Isomerism in Coordination Compounds
- 15.6 Bonding in Coordination Compounds:
  - (1) Valence Bond Theory
  - (2) Crystal Field Theory
- 15.7 Stability of Coordination Compounds in Solutions
- 15.8 Preparation of Coordination Compounds
- 15.9 Importance of Coordination Compounds
- 15.10 Organometallic Compounds

One of the most important properties of transition metals is that they form coordination or complex compounds. These compounds play a vital role in our lives. The importance of these compounds can be realised from the fact that life would not have been possible without the existence of **chlorophyll** (Mg-complex) in plants and haemoglobin (Fe-complex) in the blood of animals. One of the earliest known coordination compound is prussian blue which was accidently prepared in 1704 by a Berlin colour maker, **Diesbach**, by strongly heating animal wastes and sodium carbonate in an iron container. In 1753, Macquer prepared potassium ferrocyanide by treating prussian blue with alkali. In 1799, Tassaert obtained an orange compound, CoCl<sub>3</sub>·6NH<sub>3</sub>, by allowing a mixture of cobalt chloride and aqueous ammonia to stand in air. During the next fifty years, numerous compounds of this type containing cobalt, platinum, chromium and iron were discovered. The field of such compounds has expanded very fast in recent years and coordination compounds are playing important roles in analytical chemistry, polymerization reactions, metallurgy and refining of metals, organic synthesis, electroplating, photography, biochemistry, water purification, textile dyeing and bacteriology. In addition, the study of these compounds has enlarged our understanding of chemical bonding, certain physical properties such as spectral and magnetic properties and metabolic processes. In this chapter some basic aspects regarding coordination compounds are discussed.

#### 15.1 MOLECULAR OR ADDITION COMPOUNDS

When solutions containing two or more simple stable compounds in molecular proportions are allowed to evaporate, crystals of new substances are obtained. These substances are termed **molecular** or **addition compounds**. Some common examples are:

$$\begin{split} KCl + MgCl_2 + 6H_2O &\longrightarrow KCl \cdot MgCl_2 \cdot 6H_2O \\ &\quad Carnallite \\ K_2SO_4 + Al_2(SO_4)_3 + 24H_2O &\longrightarrow K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O \\ &\quad Alum \\ FeSO_4 + (NH_4)_2SO_4 + 6H_2O &\longrightarrow FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O \\ &\quad Mohr's \ salt \\ 4KCN + Fe(CN)_2 &\longrightarrow Fe(CN)_2 \cdot 4KCN \end{split}$$

$$\begin{array}{c} \text{CuSO}_4 \,+\, 4\text{NH}_3 \longrightarrow \text{CuSO}_4{\cdot}4\text{NH}_3 \\ \text{AgCN} \,+\, \text{KCN} \longrightarrow \text{KCN-AgCN} \\ \text{Simple stable} & \text{Addition or molecular} \\ \text{compounds} & \text{compounds} \end{array}$$

The molecular or addition compounds are of two types:

(i) **Double salts or Lattice compounds:** The addition compounds which are stable in solid state only but are broken down into individual constituents when dissolved in water are called **double salts** or **lattice compounds.** Their solutions have the same properties as the mixture of individual compounds. For example, when Mohr's salt, [FeSO<sub>4</sub>·(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>·6H<sub>2</sub>O], is dissolved in water, it exhibits the properties of FeSO<sub>4</sub> and  $(NH_4)_2SO_4$ , *i.e.*, they produce Fe<sup>2+</sup>,  $NH_4$ <sup>+</sup> and  $SO_4$ <sup>2-</sup> ions in solution. Thus, each ion has its identity in double salt.

$$FeSO_4 \cdot (NH_4)_2SO_4 \cdot 6H_2O \longrightarrow Fe^{2+}(aq.) + 2NH_4^+(aq.)$$

$$Mohr's salt \longrightarrow +2SO_4^{2-}(aq.) + 6H_2O$$

Carnallite, KCl-MgCl<sub>2</sub>·6H<sub>2</sub>O; potash alum,

K<sub>2</sub>SO<sub>4</sub>·Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·24H<sub>2</sub>O,etc., are the examples of double salts.

(ii) Coordination or complex compounds: The addition compounds in which some of the constituent ions or molecules lose their identity and when dissolved in water they do not break up completely into individual ions, are called **coordination compounds.** The properties of their solutions are different than those of their constituents. When crystals of  $CuSO_4$ ·4NH<sub>3</sub> are dissolved in water there is hardly any evidence for the presence of  $Cu^{2+}$ ions or ammonia molecules. A new ion,  $[Cu(NH_3)_4]^{2+}$ , is furnished in which ammonia molecules are directly linked with the metal ion. Similarly, the aqueous solution of  $Fe(CN)_2$ ·4KCN does not give tests of  $Fe^{2+}$  and  $CN^-$  ions but gives the test for a new ion,  $[Fe(CN)_6]^{4-}$ . The ions  $[Cu(NH_3)_4]^{2+}$  and  $[Fe(CN)_6]^{4-}$  are called **complex ions**.

$$\text{CuSO}_4 \cdot 4\text{NH}_3 \Longrightarrow \left[\text{Cu(NH}_3)_4\right]^{2+} + \text{SO}_4^{2-}$$
  
 $\text{Fe(CN)}_2 \cdot 4\text{KCN} \Longrightarrow 4\text{K}^+ + \left[\text{Fe(CN)}_6\right]^{4-}$ 

Thus, a coordination or complex compound may be defined as a molecular compound that results from the combination of two or more simple stable molecular compounds and retains its identity in the solid as well as in dissolved state. The properties of such compounds are totally different than individual constituents. A coordination compound contains very often but not always a complex ion.

Some of the common examples of these compounds are:

A complex ion may be defined as an electrically charged radical which consists of a central metal atom or ion

surrounded by a group of ions or neutral molecules or both. A coordination compound, thus, consists of either,

- (i) a simple cation and a complex anion such as  $K_4[Fe(CN)_6]$ , or
- (ii) a complex cation and a simple anion such as [Cu(NH<sub>3</sub>)<sub>4</sub>]SO<sub>4</sub>, or
- (iii) a complex cation and a complex anion such as  $[Co(NH_3)_6][Cr(C_2O_4)_3]$ , or
- (iv) a neutral molecule such as Cu(Gly)<sub>2</sub>, Ni(CO)<sub>4</sub>, Ni(DMG)<sub>2</sub>, etc.

## 15.2 TERMINOLOGY OF COORDINATION COMPOUNDS

Before further discussion, it is necessary to explain some important terms used in the study of coordination compounds. These are discussed here.

#### 3 1. Ligands

The neutral molecules; anions or cations which are directly linked with the central metal atom or ion in a complex ion are called **ligands**. The ligands are attached to the central metal ion or atom through coordinate bonds or dative linkage. With few exceptions, free ligands have at least one electron pair that is not engaged in bonding. Some examples are:

$$H-\ddot{N}-H$$
  $H-\ddot{O}$ :  $C\equiv \bar{N}$ :

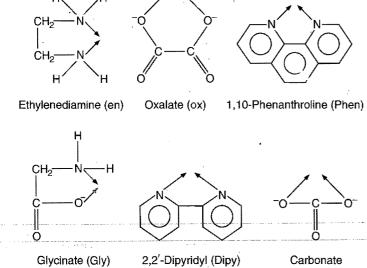

The ligand acts as a donor as it donates one or more electron pairs to the central metal atom or ion which acts as an acceptor. The ligands are thus Lewis bases and central metal ions or atoms are Lewis acids. The formation of a complex ion involves following two things:

- (i) Ligands should have lone pair or pairs of electrons which can be donated to the central metal ion or atom.
- (ii) The central atom or ion should have vacant orbitals of nearly equivalent energy as to accommodate the electrons donated by ligands. This condition is easily fulfilled by atoms or ions of transition metals.

#### Types of ligands

Ligands can be of following types depending on the number of donor atoms present in them.

- (i) Mono- or unidentate ligands: They have one donor atom, *i.e.*, they supply only one electron pair to central metal atom or ion. F<sup>-</sup>, Cl<sup>-</sup>, Br<sup>-</sup>, H<sub>2</sub>O, NH<sub>3</sub>, CN<sup>-</sup>, NO<sub>2</sub>, OH<sup>-</sup>, CO, etc., are examples of monodentate ligands.
- (ii) Bidentate ligands: Ligands which have two donor atoms and have the ability to link with central metal ion at two positions are called bidentate ligands. Some examples are:

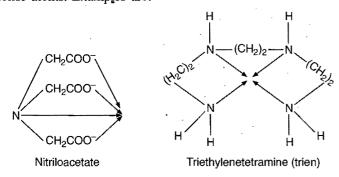

(iii) Tridentate ligands: The ligands having three donor atoms are called tridentate ligands. Examples are:

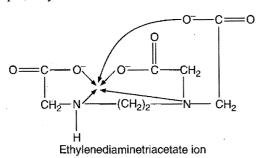

$$\begin{array}{c|c} H & H \\ H_2C & CH_2 \\ H_2C & N & CH_2 \\ \end{array}$$

$$\begin{array}{c|c} Diethylenetriamine (dien) & 2,2',2''-Terpyridine (terpy) \end{array}$$

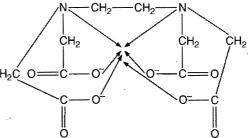

(iv) Tetradentate ligands: These ligands possess four donor atoms. Examples are:

(v) **Pentadentate ligands:** They have five donor atoms. For example, ethylenediaminetriacetate ion.

(vi) Hexadentate ligands: They have six donor atoms. The most important example is ethylenediaminetetraacetate ion

Ethylenediaminetetraacetate ion (EDTA)

(vii) Chelating ligands: A bidentate or a polydentate ligand is known as a chelating ligand if on coordination it results in the formation of a closed or cyclic ring structure. The complexes, thus formed are called chelates. The word chelate has been derived from the Greek word chele meaning claw. The complex formed by Cu<sup>2+</sup> ion with ethylenediamine is an example of a chelate.

$$\begin{bmatrix} \text{CH}_2 - \text{H}_2 \text{N} & \text{NH}_2 - \text{CH}_2 \\ \text{CH}_2 - \text{H}_2 \text{N} & \text{NH}_2 - \text{CH}_2 \end{bmatrix}^{2+} \\ \text{CH}_2 - \text{Cu}(\text{en})_2]^{2+} \end{bmatrix}$$

The following are the characteristics of chelates:

- (a) Chelating ligands form more stable complexes than monodentate ligands. This is called chelating effect. All types of polydentate ligands can act as **chelating ligands**.
- (b) The chelates containing 5 or 6-membered rings including metal atom are comparatively more stable. Chelating ligands which do not contain unsaturated groups (double bonds), in general, form five membered stable complexes while chelating ligands having unsaturated groups (double bonds) form sixmembered stable complexes.
- (c) Ligands with larger groups form more unstable rings than with smaller groups due to steric hindrance.

#### Importance of chelates

Chelates find wide applications in laboratory and industry:

- (i) A number of ions such as Cu<sup>2+</sup>, Ni<sup>2+</sup>, Mg<sup>2+</sup>, Al<sup>3+</sup>, etc., are detected and estimated by the formation of stable and coloured chelates.
- (ii) In water softening.
- (iii) In separation of lanthanides and actinides.
- (iv) In the elimination of harmful radioactive metals from body. For this purpose usually EDTA is used.
- (v) In solvent extraction.
- (vi) In food preservation.

Name	Formula	Abbreviation	Dentate character
Carbonate	CO <sub>3</sub> <sup>2</sup> -		bidentate
Oxalate	$C_2O_4^{2-}$	ох	bidentate
Ethan-1,2-diamine	$NH_2$ — $CH_2$ — $CH_2$ — $NH_2$	en	bidentate
1,2-propanediamine	NH <sub>2</sub> —CH—CH <sub>2</sub> —NH <sub>2</sub>	pn	bidentate
	CH <sub>3</sub>		
	O O		
Acetylacetonato	$CH_3$ — $C$ = $CH$ — $C$ — $CH_3$	acac	bidentate
2,2'-dipyridine		bipy	bidentate
Glycinate	NH <sub>2</sub> —CH <sub>2</sub> —COO	gly	bidentate
Diethylenetriamine	NH(C <sub>2</sub> H <sub>4</sub> NH <sub>2</sub> ) <sub>2</sub>	dien	tridentate
	OOC—CH <sub>2</sub> CH <sub>2</sub> —COO	,	
Ethylenediaminetetraacetate	$N$ —CH <sub>2</sub> —CH <sub>2</sub> —N $\langle$	edta	hexadentate
•	-OOC—CH <sub>2</sub> CH <sub>2</sub> —COO-		× ×

#### SOME COMMON POLYDENTATE LIGANDS

- Note: (i) The ligands having two or more donor atoms are also called polydentate or multidentate ligands.
  - (ii) A multidentate ligand is known as a chelating ligand if on coordination it results in formation of a closed or cyclic ring. The complexes thus formed are called *Chelates*. The chelates are comparatively more stable than ordinary complexes.
  - (iii) Polydentate ligands have flexidentate character. It is not necessary that all the donor atoms present in the polydentate ligands should form coordinate bonds with central metal atom or ion. For example, ethylenediamine tetraacetic acid (EDTA) which is hexadentate ligand can function as pentadentate or tetradentate ligand with certain metal ions. Similarly sulphate ion can also act as monodentate ligand.
  - (iv) There are certain ligands which have two or more donor atoms but in forming complexes only one donor atom is attached to metal ion. Such ligands are called ambidentate ligands. Some examples of such ligands are:

$$\begin{array}{cccc} M \longleftarrow NO_2 & M \longleftarrow ONO \\ & Nitro & Nitrito \\ M \longleftarrow CN & M \longleftarrow NC \\ & Cyano & Isocyano \\ M \longleftarrow SCN & M \longleftarrow NCS \\ & Thiocyanide & Isothiocyanide \\ \end{array}$$

#### 2. Coordination number

The number of atoms of the ligands that are directly bound to the central metal atom or ion by coordinate bonds is known as the coordination number of the metal atom or ion. It is actually the number of chemical bonds which the ligands form with the central metal atom or ion. For example, in  $[Cu(NH_3)_4]^{2+}$  the coordination number of copper is 4, in  $[Co(en)_3]^{3+}$  the coordination number of cobalt is 6 as (en) is the bidentate

ligand. The most common coordination numbers exhibited by metal ions are 2, 4 and 6. The light transition metals exhibit 4 and 6 coordination numbers while heavy transition metals may exhibit coordination number more than 6. It has been observed that in a particular oxidation state, a metal prefers to exhibit the same coordination number.

C.N. =  $\Sigma$  Number of ligands  $\times$  Dentate character of ligands

Complex	Coordination number of central metal
$K_4[Fe(CN)_6]$	. 6
$[Ag(CN)_2]^-$	2
$[Pt(NH_3)_2Cl_2]$	4 .
$[Ca(edta)]^{2-}$	6
(edta is a hexadentate ligand)	

## 3. Coordination sphere or Coordination entity and counter ions

The central metal atom or ion and the ligands that are directly attached to it are enclosed in a square bracket. This has been called coordination sphere or first sphere of attraction or coordination entity. It behaves as a single unit because the ligands present in the coordination sphere are held tightly by the metal ion. Any ion present outside this sphere is separated from the complex when the compound is dissolved in the water, or any other polar medium. The ionizable groups written outside the bracket are called counter ions.

$$K_4[Fe(CN)_6] \rightleftharpoons 4K^+ + [Fe(CN)_6]^{4-}$$
  
 $[Co(NH_3)_6]Cl_3 \rightleftharpoons [Co(NH_3)_6]^{3+} + 3Cl^{-1}$ 

The charge on the complex ion is the algebraic sum of the charges carried by central metal ion and the ligands attached to it.

Charge on the complex ion = Oxidation number of metal ion + charge on the ligands

For illustration, see following examples:

**Example 1.** Assign the charge on the following ions: (a)  $[Hg(CN)_4]^x$ , (b)  $[Co(NH_3)_2Cl_4]^x$ , (c)  $[Fe(CN)_6]^x$ . Solution.

(a) The oxidation state of Hg in the complex is +2; So

$$x = +2 + 4 \times (-1) = -2$$
, i.e.,  $[Hg(CN)_4]^{2-}$ 

(b) The oxidation state of Co in the complex is +3; So

$$x = +3 + 2 \times 0 + 4 \times (-1)$$
  
= -1, *i.e.*, [Co(NH<sub>3</sub>)<sub>2</sub>Cl<sub>4</sub>]

(c) The oxidation state of Fe in the complex is + 2; So

$$x = +2 + 6 \times (-1)$$
  
= -4, *i.e.*, [Fe(CN)<sub>6</sub>]<sup>4</sup>-

If the oxidation state of Fe in the complex is +3;

$$x = + 3 + 6 \times (-1)$$
  
= -3, i.e.,  $[Fe(CN)_6]^{3-}$ 

**Example 2.** Determine the oxidation state of metal in the complex ion,  $[PtCl_6]^{2-}$ .

**Solution.** Charge on the complex ion = Oxidation state of metal + charge on ligands

$$-2 = x + 6 \times (-1)$$
$$x = +4$$

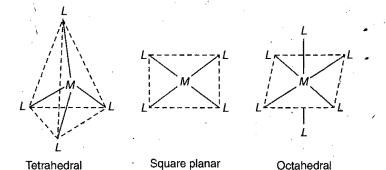

or

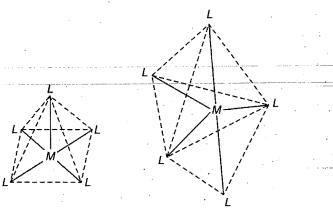

The oxidation state of Pt in the complex ion is +4.

#### 4. Coordination polyhedron

In the coordination sphere, the ligands attached to the central metal atom or ion occupy definite positions around the metal atom or ion in space giving a definite geometry to the complex ion or coordination entity. The spatial arrangement of the ligand atoms which are directly attached to the central atom or ion is called coordination polyhedron.

The generally observed coordination polyhedra are tetrahedral, square planar, octahedral, square pyramidal, and trigonal bipyramidal.

#### Square planar

Trigonal bipyramidal

#### ■ 5. Effective atomic number (EAN)

Ligands are attached with the central metal ion through donor atoms. Each donor atom donates one electron pair to the central metal ion, *i.e.*, the central metal atom or ion gains electrons from the donor atoms. In order to explain the stability of the complex, Sidgwick proposed **effective atomic number** abbreviated as EAN, which is defined as **the resultant number** of electrons with the metal atom or ion after gaining electrons from the donor atoms of the ligands. The effective atomic number (EAN) generally coincides with the atomic number of next inert gas in some cases. EAN is calculated by the following relation:

EAN = Atomic number of the metal – number of electrons lost in ion formation + number of electrons gained from the donor atoms of the ligands

The EAN values of various metals in their respective complexes are tabulated below:

Complex	Metal (Oxid. state)	At. No. of metal	Coordination number	Effective atomic number
K <sub>4</sub> [Fe(CN) <sub>6</sub> ]	+2	26	6	$(26-2) + (6 \times 2) = 36$ [Kr]
[Cu(NH <sub>3</sub> ) <sub>4</sub> ]SO <sub>4</sub>	+2	29 .	. 4	$(29 - 2) + (4 \times 2) = 35$
[Co(NH <sub>3</sub> ) <sub>6</sub> ]Cl <sub>3</sub>	+3	27	6	$(27-3) + (6 \times 2) = 36$ [Kr]
Ni(CO) <sub>4</sub>	0	28	4	$(28 - 0) + (4 \times 2) = 36$ [Kr]
K <sub>2</sub> [Ni(CN) <sub>4</sub> ]	+2	28	4	$(28 - 2) + (4 \times 2) = 34$
K <sub>2</sub> [PtCl <sub>6</sub> ]	+4	78	6.	$(78 - 4) + (6 \times 2) = 86 [Rn]$

$K_3[Cr(C_2O_4)_3]$	+3	24	. 6	$(24 - 3) + (6 \times 2) = 33$
K <sub>3</sub> [Fe(CN) <sub>6</sub> ]	+3	26	6	$(26-3) + (6 \times 2) = 35$
K <sub>2</sub> [HgI <sub>4</sub> ]	+2	80	4	$(80-2) + (4 \times 2) = 86$ [Rn]
[Ag(NH <sub>3</sub> ) <sub>2</sub> ]Cl	+1	47	2	$(47-1) + (2 \times 2) = 50$
K <sub>2</sub> [PdCl <sub>4</sub> ]	+2	46	4	$(46 - 2) + (4 \times 2) = 52$

Just as the octet is useful in formulating the bonding in compounds of the light elements, the notion of an EAN provides a rough guide for bonding in coordination compounds. Quite a few, but not all, metals achieve the EAN of a noble gas through coordination (see above table). The EAN concept has been particularly successful for complexes of low valent metals (oxidation state  $\leq +2$ ).

#### 6. Homoleptic and heteroleptic complexes

Complexes in which a metal is bound to only one kind of donor groups, e.g.,  $[Cr(NH_3)_6]^{3+}$  are known as homoleptic. Other examples are : $[Fe(CN)_6]^{3-}$ ,  $[PtCl_4]^{2-}$ ,  $[HgI_4]^{2-}$  etc.

Complexes in which a metal is bound to more than one kind of donor groups are known as heteroleptic. Examples are :  $[Co(en)_2Cl_2]^+$ ,  $[Cr(NH_3)_4Cl_2]^+$ ,  $[Fe(H_2O)_4(C_2O_4)]^+$ , etc.

#### 7. Homonuclear and polynuclear complexes

Complexes in which only one metal atom is present are known as homonuclear complexes. Complexes in which more than one metal atom is present are known as polynuclear complexes.

## 15.3 NOMENCLATURE OF COORDINATION COMPOUNDS

Since several thousands of complexes (coordination compounds) are known and the number is constantly increasing, it is necessary to adopt a uniform system of naming these compounds. The International Union of Pure and Applied Chemistry (IUPAC) published rules for the systematic naming of coordination compounds in 1957. Some modifications in these rules were made in 1962 and 1971.

However, trivial names for certain coordination compounds are still in use, e.g.,  $K_4[Fe(CN)_6]$  and  $K_3[Fe(CN)_6]$  are called as potassium ferrocyanide and potassium ferricyanide even today.

The following rules are adopted these days for naming all types of coordination compounds:

- (1) If a coordination compound is ionic, the name of cation is given first whether or not it is the complex ion followed by the name of the anion just like naming a simple salt. The names of cation and anion are separated by a space.
- (2) Within a complex ion, the ligands are named first followed by the metal ion.

#### Names of the Ligands

(i) Anionic ligands ending with -ide are named by replacing -ide with suffix -o or replacing -e by -o.

Anion	Symbol	Name as ligand
Chloride	ci-	Chlorido
Bromide	Br <sup>-</sup>	Bromido
Cyanide	$CN^-$	Cyano
Oxide	$O^{2-}$	Охо
Peroxide	$O_2^{2-}$	Peroxo
Hydroxide	OH-	Hydroxo
Sulphide	S <sup>2-</sup>	Sulphido -
Amide	$NH_2^-$	Amido
Nitride	$N^{3-}$	Nitrido
Phosphide	P <sup>3-</sup>	Phosphido

Ligands whose names end in -ite or -ate become -ito or -ato, i.e., by replacing the ending -e with -o.

Anion	Symbol	Name as ligand
Carbonate	$CO_3^{2-}$	Carbonato
Oxalate	$C_2O_4^{2-}$	Oxalato
Sulphate	$SO_4^{2-}$	Sulphato
Nitrate	$NO_3^-$	Nitrato
Sulphite	$SO_3^{2-}$	Sulphito
Acetate	CH <sub>3</sub> COO	Acetato
Nitrite	ONO-	(bonded through oxygen) Nitrito-o
	$NO_2^-$	(bonded through nitrogen) Nitrito-n
		or Nitro

(ii) Neutral ligands are called with the same names as their neutral molecules or with their special names, e.g.,

$$\begin{array}{c} C_6H_5N \text{ or } & \longrightarrow \text{Pyridine} \\ PH_3 & \longrightarrow \text{Phosphine} \\ (C_6H_5)_3P & \longrightarrow \text{Triphenylphosphine} \\ H_2N - CS - NH_2 & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ &$$

**Note:** In the case of poly-dentate amino ligands we use single 'm' in the spelling, *i.e.*, amine is written, *e.g.*,

iii) Positively charged ligands have suffix -ium.

NH<sub>4</sub><sup>+</sup> Ammonium; NO<sup>+</sup> Nitrosylium; NH<sub>2</sub>—NH<sub>3</sub><sup>+</sup> Hydrazinium; NO<sub>2</sub><sup>+</sup> Nitronium

(iv) If the number of a particular ligand is more than one in the complex ion, the number is indicated by using Greek numbers such as di, tri, tetra, penta, hexa, etc.

However, when the name of the ligand includes a number, e.g., dipyridyl, ethylenediamine, then bis, tris, tetrakis are used in place of di, tri, tetra, etc.

(v) Order of naming ligands: When more than one type of ligands are present, they are named in alphabetical order without separation by hyphen. This rule has come in force after 1971 convention.

Note: In the old system, (i) the ligands are named in the order of negative, neutral and positive without separation by hyphens.
(ii) when there are several ligands of same kind, these are listed alphabetically.

For example, in the complex  $[Cr(NH_3)_4Cl(NO_2)]^+$ , the ligands are named in the order of ammine, chlorido and nitrito-N in accordance to new convention. However, according to old convention, the ligands are named in the order of chlorido, nitrito-N and ammine (first negative ligands in alphabetical order and then neutral ligand).

- (3) The oxidation state of the central metal is shown by Roman numeral in bracket immediately following its name.
- (4) Complex positive ions and neutral coordination compounds have no special ending but complex negative ions always end in the suffix -ate. In most of the cases, the suffix -ate is fixed to English names of the metals but in some cases -ate is fixed with Latin names of metals.

Name of components present in coordination sphere are written in continuum, e.g.,

K<sub>3</sub>[Fe(CN)<sub>5</sub>NO] Potassium pentacyanonitrosylferrate(II)

Continuum

Element	Metal as named in anionic complex
Cobalt	Cobaltate
Nickel	Nickelate
Chromium	Chromate
Iron	Ferrate
Copper	Cuprate
Silver	Argentate
Lead	Plumbate

Note: In the case of mercury we may use both mercurate and hydrazinate.

(5) The name of the neutral coordination compound is given in one word only as the name of Ni(CO)<sub>4</sub> is tetracarbonylnickel (0). The following examples will make the rules more clear.

#### Coordination compounds containing complex cationic ion:

$[Pt(NH_3)_6]Cl_4$	Hexaammineplatinum(IV) chloride
[CO(NH <sub>3</sub> ) <sub>4</sub> H <sub>2</sub> OCl]Cl	Tetra ammine a quo chlorido cobalt (III) chloride
$[Cu(en)_2]SO_4$	Bis (ethane-1,2-diamine) copper(II) sulphate
$\left[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2\right]^+$	Tetraaquodichloridochromium(III) ion
$[Fe(H_2O)_4(C_2O_4)]_2SO_4$	Tetraaquooxalatoiron(III) sulphate
[Cr(NH <sub>3</sub> ) <sub>4</sub> (ONO)Cl]NO <sub>3</sub>	Tetraamminechloridonitrito-o-chromium(III)
	nitrate
[Ag(NH <sub>3</sub> ) <sub>2</sub> ]CI	Diammine silver(I) chloride
[Co(NH <sub>3</sub> ) <sub>5</sub> (NCS)]Cl <sub>2</sub>	Pentaammineisothiocyanatocobalt(III)
	chloride
$[\{(C_6H_5)_3P\}_3Rh]Cl$	Tris (triphenylphosphine) rhodium(I)
	chloride

#### Coordination compounds containing complex anionic ion:

K <sub>4</sub> [Fe(CN) <sub>6</sub> ]	Potassium hexacyanoferrate (II)
K <sub>3</sub> [Fe(CN) <sub>6</sub> ]	Potassium hexacyanoferrate (III)
$K_3[Cr(C_2O_4)_3]$	Potassium trioxalatochromate (III)
$K_3[Co(C_2O_4)_2Cl_2]$	Potassium dichloridodioxalatocobaltate (III)
$K_2[HgI_4]$	Potassium tetraiodidomercurate (II)
K <sub>2</sub> [PtCl <sub>6</sub> ]	Potassium hexachloridoplatinate (IV)
$Na[Ag(CN)_2]$	Sodium dicyanoargentate (I)
$[Ni(CN)_4]^{2-}$	Tetracyanonickelate(II) ion
$Na_3[Co(NO_2)_6]$	Sodium hexanitrocobaltate (III)
K <sub>3</sub> [Fe(CN) <sub>5</sub> NO]	Potassium pentacyanonitrosyl ferrate (II)

## Coordination compounds containing complex cationic and anionic ions:

$[Cr(NH_3)_6][Co(CN)_6]$	Hexaamminechromium (III)
	hexacyanocobaltate (III)
[Pt(NH <sub>3</sub> ) <sub>4</sub> ][CuCl <sub>4</sub> ]	Tetraammineplatinum (II)
	tetrachloridocuprate (II)
$[Cr(NH_3)_6][Co(C_2O_4)_3]$	Hexaamminechromium (III)
*	trioxalatocobaltate (III)
$[Pt(py)_4][PtCl_4]$	Tetrapyridine platinum (II)
	tetrachloridoplatinate (II)

#### Non-ionic coordination compounds:

Fe(CO) <sub>5</sub>	Pentacarbony	liron(0)
$[\mathrm{Co}(\mathrm{NO}_2)_3(\mathrm{NH}_3)_3]$	Triamminetri	nitro cobalt (III)
$Cu(Gly)_2$	Diglycinatoco	opper (II)
Ni(DMG)2	Bis (dimethyl	glyoximato) nickel (II)

(6) Bridging groups in bidentate ligands: In a polyatomic complex which contains two or more central metal ions, the ligands which act as bridge between two metal atoms, the Greek letter  $\mu$  (mu) separated by a hyphen is written before their names. For example, the complex

Bis (ethane-1,2-diamine) cobalt(III)-μ-amido-μ-hydroxo bis (ethane-1,2-diamine) cobalt(III) sulphate

Or

Tetrakis (ethane-1,2-diamine) - $\mu$ -amido- $\mu$ -hydroxodicobalt (III) sulphate.

The complex 
$$\left[ (H_2O)_4 Fe \middle\backslash OH \middle\rangle Fe(H_2O)_4 \right] (SO_4)_2 \text{ is }$$
 named as:

Tetraaquoiron(III) - u-dihydroxotetraaquoiron(III) sulphate.

## Writing the formula of a coordination compound from its IUPAC name

Following rules are followed in writing the formula of a coordination compound:

- 1. Formula of the cation whether simple or complex is written first, followed by that of an anion.
  - 2. The coordination sphere is written in square brackets.
- **3.** The following sequence of symbols within the coordination sphere is followed:
  - (i) Metal atom
- (ii) Anionic ligands
- (iii) Neutral ligands
- (iv) Cationic ligands
- (a) If there are a number of ligands of same type (anionic, neutral or cationic), they are listed alphabetically, according to first alphabet of their formula. For example, if NO<sub>3</sub>, SO<sub>4</sub><sup>2</sup>, OH<sup>-</sup>, Br<sup>-</sup>, etc., are present, they are written as Br<sup>-</sup>, NO<sub>3</sub>, OH<sup>-</sup> and SO<sub>4</sub><sup>2</sup>.
- (b) When two ligands have same defining atom, the ligand with fewer such atoms is cited first followed by the ligand having more atoms. For example,  $SO_4^{2-}$  precedes  $S_2O_3^{2-}$ .
- (c) When the number of defining atoms are same, subsequent, symbol decides the sequence. For example,  $NH_2^-$  precedes  $NO_2$  because H comes before O.
- **4.** Polyatomic ligands are enclosed in parentheses but all ligands are formulated without any space in between.
- 5. The number of cations or anions to be written in the formula is calculated on the basis that total positive charge on the cation must be equal to the total negative charge on the anion, as the complex as a whole is electrically neutral.
- 6. Sometimes abbreviations for certain ligands are used in parentheses instead of their structural formulae. For example,

(en)	ethylenediamine	(dmg)	dimethylglyoximato
	(ethane-1, 2-diamine)		•
(dien)	diethylenetriamine	(py)	pyridine (pyridyl)
(trien)	triethylenetetraamine	(phen)	1,10-phenanthroline
(acac)	acetylacetonato	(gly)	glycinato
(dipy)	dipyridyl	(tripy)	tripyridyl
(edta)	ethane-1,2-diamine	(ox)	oxalato
	tetraacetato		

Few examples are given here to explain the above rules.

#### 1. Potassium amminetrichloridoplatinate(II)

Cation:  $K^+$ ; Anion:  $[PtCl_3(NH_3)]^x$ 

x =oxid. number of Pt + algebraic sum of charges carried by ligands

$$= + 2 + 3 \times (-1) + 0 = -1$$

Thus, the charge on the complex anion is -1.

Therefore, the formula of the coordination compound is  $K[PtCl_3(NH_3)]$ 

#### 2. Tetraammineaquachloridocobalt(III) chloride

Cation: [CoCl(H<sub>2</sub>O)(NH<sub>3</sub>)<sub>4</sub>]<sup>x</sup>

x =oxid. number of Co + algebraic sum of the charges on the ligands

$$= +3 + (-1) + 0 + 4 \times 0 = +2$$

 $Anion = Cl^{-}$ 

(Two anions neutralise the charge on the cation)
Therefore, the formula of the given coordination compound

#### 3. Tetraamminediaquacobalt(III) chloride

Cation :  $[Co(NH_3)_4(H_2O)_2]^x$ +3 + 0 + 0 = x

x = 3

: Molecular formula of the complex is:

 $[CO(NH_3)_4(H_2O)_2]Cl_3$ 

#### 4. Sodium ethane-1,2-diaminetetraacetatochromate(II)

Cation: Na<sup>+</sup>

Anion:  $[Cr(edta)]^x$ 

x = oxid. state of chromium + algebraic sum of charges on the ligands

$$= +2 + (-4) \times 1 = -2$$

Thus, two Na<sup>+</sup> ions should be present in the complex to neutralize the charge.

Therefore, molecular formula of the complex will be  $Na_2[Cr(edta)]$ 

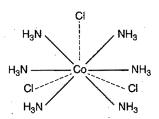

#### 15.4 WERNER'S COORDINATION THEORY

Werner, in 1893, proposed coordination theory to explain the properties and structures of various metal ammines of cobalt, chromium, platinum, etc. It was first successful attempt which satisfactorily described the formation of coordination compounds from stable molecules. The important postulates of coordination theory are:

- 1. Every element exhibits two types of valencies:
- (a) Primary valency and (b) Secondary valency.

In modern terminology, **primary valency** corresponds to the oxidation state of the central metal and secondary valency represents the coordination number of the metal. Primary valency is satisfied by negative ions. This is also called **principal**, **ionisable** or **ionic valency**. Its attachment to the metal is shown by dotted lines.

The secondary valency is satisfied by neutral molecules or negative ions. This valency is non-ionic or non-ionisable. The donor atoms of the ligands which satisfy the coordination number are directly attached to the metal atom and shown by thick lines. Thus, the coordination compound, CoCl<sub>3</sub>·6NH<sub>3</sub>, may be represented as:

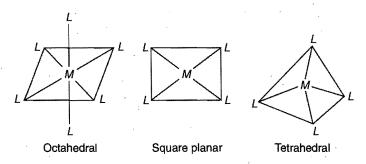

Every metal has a fixed coordination number. For example, Co(III) and Pt(IV) were recognised as having coordination number 6 while Cu(II) has 4. In order to designate materials held by secondary valencies, it has become customary to enclose the metal and all such materials in square bracket when writing formulae. For example, coordination compounds such as CoCl<sub>3</sub>·6NH<sub>3</sub> and PtCl<sub>4</sub>·6NH<sub>3</sub> are written as [Co(NH<sub>3</sub>)<sub>6</sub>]Cl<sub>3</sub> and [Pt(NH<sub>3</sub>)<sub>6</sub>]Cl<sub>4</sub> respectively.

2. Every element tends to satisfy both its primary and secondary valencies. A negative ion when present in the coordination sphere shows a dual behaviour. It may satisfy both primary and secondary valencies. The presence of negative ion in the coordination sphere reduces the charge on the complex ion by the amount of charge possessed by it and the negative ions present in the coordination sphere are not ionised. Thus, the following coordination compounds will have varying number of ionisable chlorine atoms but coordination number remains the same.

Coordination	Modern formula	Charge on the cation	Coordination number (secondary val.)	Primary valency	Total no. of ions
PtCl <sub>4</sub> ·6NH <sub>3</sub>	[Pt(NH <sub>3</sub> ) <sub>6</sub> ]Cl <sub>4</sub>	+4	6	4	5
PtCl <sub>4</sub> ·5NH <sub>3</sub>	[Pt(NH <sub>3</sub> ) <sub>5</sub> Cl]Cl <sub>3</sub>	+3	6	4	4
PtCl <sub>4</sub> ·4NH <sub>3</sub>	[Pt(NH <sub>3</sub> ) <sub>4</sub> Cl <sub>2</sub> ]Cl <sub>2</sub>	+2	6	4.	3
$PtCl_{4} \cdot 3NH_{3}$	[Pt(NH <sub>3</sub> ) <sub>3</sub> Cl <sub>3</sub> ]Cl	+1	6	4	2
PtCl <sub>4</sub> ·2NH <sub>3</sub>	[Pt(NH <sub>3</sub> ) <sub>2</sub> Cl <sub>4</sub> ]	Ó	6	4	Non-electro- lyte

3. The ligands which satisfy the secondary valencies are directed towards fixed positions in space. The geometry of the complex ion depends on the coordination number. If the metal

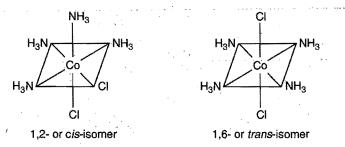

has coordination number 6, the complex is octahedral, *i.e.*, six positions around the metal are occupied by six donor atoms of the ligands octahedrally. On the other hand, if the coordination number is 4, the geometry of the complex may be tetrahedral or square planar. This postulate predicted the existence of different types of isomerism in coordination compounds.

#### **Examples:**

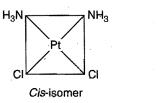

Octahedral	Square planar	Tetrahedral
$[Cr(NH_3)_6]^{3+};$	[Ni(CN) <sub>4</sub> ] <sup>2-</sup> ;	[Ni(CO) <sub>4</sub> ];
$[Co(NH_3)_6]^{3+};[Cr(H_2O)_6]^{3+};$	$[Ni(NH_3)_4]^{2+};$	$[CuX_4]^{2-}$ ; $[ZnCl_4]^{2-}$ ;
$[Fe(CN)_6]^{2-}; [Fe(F_6)]^{3-};$	$[Cu(NH_3)_4]^{2+};$	$[NiX_4]^{2-}$
$[Pt(NH_3)_6]^{4+}; [PtCl_6]^{2-}$	,	$X = Cl^-, Br^-, I^-$

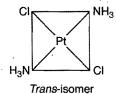

In [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]Cl, Werner was able to isolate two isomers. He predicted an octahedral structure for coordination number 6, because only octahedral structure can form two isomers (l, 2- and 1, 6-). The planar hexagonal and trigonal prism arrangements will give three isomers each.

Similarly, the existence of two geometrical isomers of the complex, Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>, was proved by accepting square planar configuration.

The postulates of Werner's coordination theory were actually based on experimental evidences rather than theoretical. A large number of metal ammines were studied by Werner using molar conductance values as to ascertain the number of ions per molecule and chemical methods such as precipitation of Cl<sup>-</sup> by AgNO<sub>3</sub> as to determine the number of ionisable Cl<sup>-</sup> ions per molecule. The following experimental data regarding cobalt ammines well supported the postulates that the secondary valency of 6 is maintained in all the cobalt ammines and when the Cl<sup>-</sup> ion enters the coordination sphere, it decreases the positive charge on the complex ion by one unit.

Molecular formula	Molar conductance	No. of ions in molecules	Ionisable Cl <sup>-</sup> ions (precipitation with AgNO <sub>3</sub> )	Secondary valency	Ionic formulation
CoCl <sub>3</sub> 6NH <sub>3</sub>	430	4	3	6	[Co(NH <sub>3</sub> ) <sub>6</sub> ]Cl <sub>3</sub>
CoCl <sub>3</sub> 5NH <sub>3</sub> ·H <sub>2</sub> O	430	4	3	6	[Co(NH <sub>3</sub> ) <sub>5</sub> H <sub>2</sub> O]Cl <sub>3</sub>
CoCl <sub>3</sub> 5NH <sub>3</sub>	250	3	2	6	$[Co(NH_3)_5Cl]Cl_2$
CoCl <sub>3</sub> 4NH <sub>3</sub>	100	2 .	1	6 .	[Co(NH <sub>3</sub> ) <sub>4</sub> Cl <sub>2</sub> ]Cl
CoCl <sub>3</sub> 3NH <sub>3</sub>	0	Non-e	lectrolyte	6	[Co(NH <sub>3</sub> ) <sub>3</sub> Cl <sub>3</sub> ]

Werner theory is also supported by the conductance measurements.

In above complexes A, B, C and D, the primary valency is satisfied by 3, 2, 1 and 0, Cl<sup>-</sup> ions respectively. Thus, conductance of equimolar aqueous solution of these complex lie in following order:

## 15.5 ISOMERISM IN COORDINATION COMPOUNDS

The compounds having same molecular formula but different physical and chemical properties on account of different structures are called **isomers** and the phenomenon as **isomerism**. Isomerism in coordination compounds may be divided into two main types:

(1) Structural isomerism, (2) Stereo-isomerism

#### 1. Structural Isomerism

It is displayed by compounds that have different ligands within their coordination spheres. The different types of structural isomerism shown by coordination compounds are discussed below:

(i) Ionisation isomerism: This type of isomerism arises when the coordination compounds give different ions in solution. For example, there are two isomers of the formula Co(NH<sub>3</sub>)<sub>5</sub>BrSO<sub>4</sub>.

$$[\text{Co(NH}_3)_5\text{Br}]\text{SO}_4 \iff [\text{Co(NH}_3)_5\text{Br}]^{2+} + \text{SO}_4^{2-}$$
(Violet)

Pentaamminebromidocobalt(III) ion

This isomer gives a white precipitate of BaSO<sub>4</sub> with BaCl<sub>2</sub> solution.

$$[Co(NH_3)_5SO_4]Br \rightleftharpoons [Co(NH_3)_5SO_4]^+ + Br^-$$
(Red) Pentaamminesulphato-
cobalt(III) ion

Above isomer gives light yellow precipitate with AgNO<sub>3</sub> solution. Other examples of ionisation isomerism are:

[Pt(NH <sub>3</sub> ) <sub>4</sub> Cl <sub>2</sub> ]Br <sub>2</sub> Tetraamminedichlorido- platinum(IV) bromide	and	[Pt(NH <sub>3</sub> ) <sub>4</sub> Br <sub>2</sub> ]Cl <sub>2</sub> Tetraamminedibromido- platinum(IV) chloride
[Co(NH <sub>3</sub> ) <sub>4</sub> Cl <sub>2</sub> ]NO <sub>2</sub>	and	[Co(NH <sub>3</sub> ) <sub>4</sub> ClNO <sub>2</sub> ]Cl
Tetraamminedichlorido-		Tetraamminechloridonitrito-n-
cobalt(III) nitrite		cobalt(III) chloride

- (ii) Hydrate isomerism: This type of isomerism arises when different number of water molecules are present inside and outside the coordination sphere. This isomerism is best illustrated by the three isomers that have the formula CrCl<sub>3</sub>·6H<sub>2</sub>O.
- (a) [Cr(H<sub>2</sub>O)<sub>6</sub>]Cl<sub>3</sub>—Violet. All the six water molecules are coordinated to Cr. It has three ionisable chloride ions.
- (b) [Cr(H<sub>2</sub>O)<sub>5</sub>Cl]Cl<sub>2</sub>·H<sub>2</sub>O—Green. Five water molecules are coordinated to Cr. It has two ionisable chloride ions. One water molecule outside the coordination sphere can be easily lost.
- (c)  $[Cr(H_2O)_4Cl_2]Cl\cdot 2H_2O$ —Green. Four water molecules are coordinated to Cr. It has one ionisable  $Cl^-$  ion. Other examples of hydrate isomerism are:

(iii) Coordination isomerism: This type of isomerism is observed in the coordination compounds having both cationic and anionic complex ions. The ligands are interchanged in both the cationic and anionic ions to form isomers. Some examples are:

[Pt(NH <sub>3</sub> ) <sub>4</sub> ][CuCl <sub>4</sub> ] Tetraammineplatinum(II) tetrachloridocuprate(II)	and	[Cu(NH <sub>3</sub> ) <sub>4</sub> ][PtCl <sub>4</sub> ] Tetraamminecopper(II) tetrachloridoplatinate(II)
$[Cr(NH_3)_6][Co(C_2O_4)_3] \\ Hexaamminechromium(III) \\ trioxalatocobaltate(III)$	and	[Co(NH <sub>3</sub> ) <sub>6</sub> ][Cr(C <sub>2</sub> O <sub>4</sub> ) <sub>3</sub> ] Hexaamminecobalt(III) trioxalatochromate(III)

[Cr(NH<sub>3</sub>)<sub>6</sub>][Cr(SCN)<sub>6</sub>] Hexaamminechromium(III) hexathiocyanatochromate(III) and

[Cr(NH<sub>3</sub>)<sub>4</sub>(SCN)<sub>2</sub>][Cr(NH<sub>3</sub>)<sub>2</sub>(SCN)<sub>4</sub>]

Tetraamminedithiocyanatochromium(III) diamminetetrathiocyanatochromate(III)

(iv) Linkage isomerism: This type of isomerism occurs in complex compounds which contain **ambidentate** ligands like  $NO_2^-$ ,  $SCN_2^-$ ,  $CN_2^-$ ,  $S_2O_3^{2-}$  and CO. These ligands have two donor atoms but at a time only one atom is directly linked to the central metal atom of the complex. These types of isomers are distinguished by infra-red (I.R.) spectroscopy. For example,  $[Co(NH_3)_5NO_2]Cl_2$  and  $[Co(NH_3)_5ONO]Cl_2$  are linkage isomers as  $NO_2^-$  is linked through N or through O.

and

and

[Co(NH<sub>3</sub>)<sub>5</sub>NO<sub>2</sub>]Cl<sub>2</sub> Pentaamminenitrito-*n*-cobalt(III) chloride (yellow) [Co(NH<sub>3</sub>)<sub>5</sub>ONO]Cl<sub>2</sub> Pentaamminenitrito-o-cobalt(III)

chloride (red)

Another example of this type of isomerism is:

[Pd(dipy)(SCN)<sub>2</sub>] Dipyridyldithiocyanatopalladium(II) [Pd(dipy)(NCS)<sub>2</sub>] Dipyridyldiisothiocyanatopalladium(II)

(v) Polymerisation isomerism: This type of isomerism exists in compounds having same stoichiometric composition but different molecular compositions. The molecular compositions are simple multiples of the simplest stoichiometric arrangement. For example in the following three compounds, the second and third compounds are polymers of the first.

[Note: (ii) and (iii) compounds are actually not the examples of polymerisation, *i.e.*, (i) compound is not acting as a monomer in the formation of (ii) and (iii) compounds.]

(vi) Coordination position isomerism: This type of isomerism is exhibited by polynuclear complexes by changing the position of ligands with respect to different metal atoms present in the complex. For example,

$$\begin{bmatrix} (NH_3)_4 Co & NH_2 \\ O_2 & Co(NH_3)_2 Cl_2 \end{bmatrix}^{24}$$
Unsymmetrical

(Both the chloro ligands are with same cobalt ion.)

and  $\left[ (NH_3)_3 ClCo \bigvee_{O_2} NH_2 Co(NH_3)_3 Cl \right]^{2+}$ Symmetrical

(Same ligands are linked with both cobalt ions.)

#### 2. Stereo-isomerism

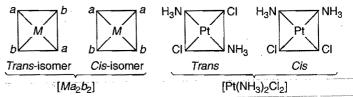

Compounds are stereo-isomers when they contain the same ligands in their coordination spheres but differ in the way that these ligands are arranged in space. Stereo-isomerism is of two types, *viz.*, geometrical isomerism and optical isomerism.

(1) Geometrical isomerism: This isomerism is due to ligands occupying different positions around the central metal atom or ion. The ligands occupy positions either adjacent or opposite to one another. This type of isomerism is also known as *cis*- and *trans*- isomerism.

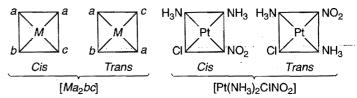

Geometrical isomerism is very much common in coordination number 4 and 6 complexes.

**Square planar complexes** (coordination number four) exhibit geometrical isomerism.

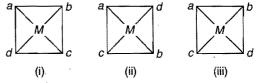

(i) Complexes with general formula,  $Ma_2b_2$  (where both a and b are monodentate) can have cis- and trans-isomers.

(ii) Complexes with general formula,  $Ma_2bc$  can have *cis*-and *trans*-isomers.

(iii) Complexes with general formula, *Mabcd* can have three isomers.

**Example:**  $[Pt(NH_3)(NH_2OH)(NO_2)(py)]NO_2$ .

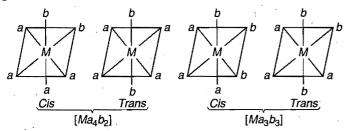

(iv) Square planar complexes having unsymmetrical bidentate ligands can also show geometrical isomerism. For example, platinum glycinato complex, [Pt(Gly)<sub>2</sub>], exhibits geometrical isomerism.

 $[Ma_4]^{n\pm}$  and  $[Ma_3b]^{n\pm}$  type square planar complexes do not show geometrical isomerism.

#### Tetrahedral and Linear complexes

These complexes do not show geometrical isomerism because the geometry of these ligands is definite, *e.g.*, in tetrahedral complexes, any two ligands lie at 109°28'; while in linear complexes, the two ligands lie at 180°.

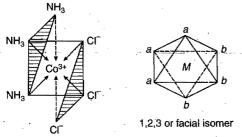

Octahedral complexes of the type  $Ma_4b_2$  and  $Ma_3b_3$  exhibit geometrical isomerism.

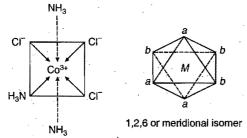

**Example:** [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]Cl, [Co(NH<sub>3</sub>)<sub>3</sub>Cl<sub>3</sub>] Octahedral complexes of general formula, *Mabcdef*, can have fifteen geometrical isomers.

#### Facial and Meridional Isomers

A set of three ligands (similar) may be arranged on an octahedron in all *cis*-fashion, giving facial or 'fac' isomer. In other words, three similar ligands on the same face of octahedron give rise to the facial isomer.

A set of three similar ligands may be arranged on an octahedron with one pair *trans* (meridian of octahedron), giving rise to meridional or 'mer' isomer.

**Note:** 1. Geometrical isomerism is not observed in complexes of coordination number 2 and 3.

- Geometrical isomerism is not observed in complexes of coordination number 4 of tetrahedral geometry.
- 3. The complexes of general formulae,  $Ma_3b$  or  $Mab_3$ , or  $Ma_4$ , of square planar geometry do not show geometrical isomerism.
- 4. The complexes of general formulae,  $Ma_6$  and  $Ma_5b$ , of octahedral geometry do not show geometrical isomerism.
- 'Fac' and 'mer' isomers of an [Ma<sub>3</sub>b<sub>3</sub>] octahedral complex are optically inactive.

(2) Optical isomerism: A coordination compound which can rotate the plane of polarised light is said to be optically active. When the coordination compounds have same formula but differ in their abilities to rotate directions of the plane of polarised light are said to exhibit optical isomerism and the

molecules are optical isomers. The optical isomers are pair of molecules which are non-superimposable mirror images of each other. The essential requirement for a substance to be optically active is that the substance should not have a plane of symmetry in its structure. The isomer which rotates the plane of polarised light to right direction is termed dextro (d-form) while the isomer which rotates the plane of polarised light to left direction is termed laevo (l-form). The two optically active isomers are collectively called enantiomers. Enantiomers are mirror image to each other and their physical properties are different.

Optical isomerism is expected in tetrahedral complexes of the type *Mabcd* but no optical isomer has been isolated until now.

However, compounds containing two unsymmetrical bidentate ligands have been resolved into optical isomers and are known for Be(II), Zn(II) and B(III). For example, Bis-benzoylacetonato-beryllium(II) exhibits optical isomerism.

Optical isomers rarely occur in square planar complexes on account of the presence of axis of symmetry.

Optical isomerism is very common in octahedral complexes. Octahedral complexes of general formulae,

$$[Ma_2b_2c_2]^{n\pm}$$
,  $[Mabcdef]$ ,  $[M(AA)_3]^{n\pm}$ ,  $[M(AA)_2a_2]^{n\pm}$ , (where  $AA$  = symmetrical bidentate ligands)

$$[M(AA)_2ab]^{n\pm}$$
 and  $[M(AB)_3]^{n\pm}$ 

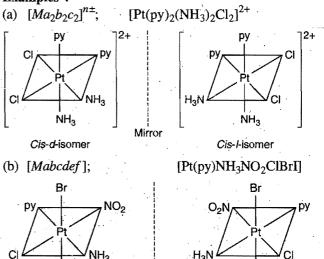

(where AB unsymmetrical ligands)

I-isomer

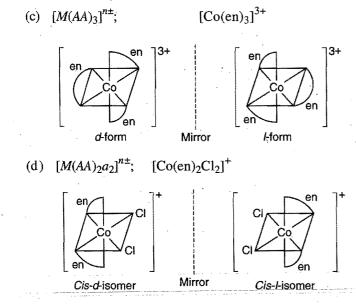

show optical isomerism.

d-isomer

#### Examples:

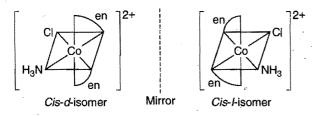

Mirror

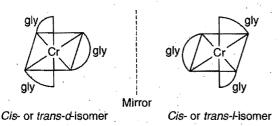

Trans form of  $[M(AA)_2a_2]^{n\pm}$  does not show optical isomerism.

(e)  $[M(AA)_2ab]^{n\pm}$ ;  $[Co(en)_2NH_3Cl]^{2+}$ 

(f)  $[M(AB)_3]$ ;  $[Cr(gly)_3]$ 

Some more examples are:

 $[Cr(ox)_3]^{3-}$ ;  $[Fe(dipy)_3]^{2+}$ ;  $[Cr(ox)_2(H_2O)_2]^-$ ;  $[Pt(en)_3]^{4+}$ 

## 15.6 BONDING IN COORDINATION COMPOUNDS

Werner was first to describe the structures and the existence of various types of isomerism in coordination compounds. However, the nature of bonding between central metal atom and ligands in the coordination sphere has been explained by the three well-known theories. These theories are:

- 1. Valence bond theory
- 2. Crystal field theory
- 3. Ligand field or molecular orbital theory

#### 

It is the simplest of the three theories and was developed mainly by Pauling. It describes the bonding in terms of hybridized orbitals of the central metal atom or ion. The theory mainly deals with the geometry (*i.e.*, shape) and magnetic properties of the complexes. The salient features of the theory are:

- (i) The central metal loses a requisite number of electrons to form the ion. The number of electrons lost is the valency of the resulting cation. In some cases, the metal atom does not lose electrons.
- (ii) The central metal ion or atom (as the case may be) makes available a number of empty s-, p- and d-atomic orbitals equal to its coordination number. These vacant orbitals hybridize together to form hybrid orbitals which are same in the number as the atomic orbitals hybridizing together. They are vacant, equivalent in energy and have definite geometry.

Some of the common hybridized orbitals met in the coordination compounds are listed below:

(For details see chapter 2 on valency.)

Coordi- nation number	Type of hybri- dization	Geometry	Examples
2	sp	Linear	$[Ag(NH_3)_2]^+$ , $[Ag(CN)_2]^-$
3 .	$\frac{sp^2}{sp^3}$	Trigonal planar	[HgI <sub>3</sub> ]
4	$sp^3$	Tetrahedral	$Ni(CO)_4$ , $[Ni(X_4)]^{2-}$ , $[ZnCl_4]^{2-}$ ,
	dsp <sup>2</sup>	Cayana planas	$[CuX_4]^2$ , where $X = C\Gamma$ , Br, $\Gamma$ $[Ni(CN)_4]^2$ , $[Cu(NH_3)_4]^2$
*	asp	Square planar	$[Ni(NH_3)_4]^{2+}$
5	$dsp^3$	Trigonal bipyramidal	Fe(CO) <sub>5</sub> , $[CuCl_5]^{3-}$
	$sp^3d$	Square pyramidal	[SbF <sub>5</sub> ] <sup>2-</sup>
6	1	Octahedral	$[Cr(NH_3)_6]^{3+}$ , $[Fe(CN)_6]^{3-}$
	$sp^3d^2$	(Inner orbital) (Outer orbital)	$[FeF_6]^{3-}$ , $[Fe(H_2O)_6]^{2+}$ , $[Ni(NH_3)_6]^{2+}$

- (iii) The non-bonding electrons of the metal occupy the inner orbitals. These are grouped in accordance with Hund's rule, however, under the influence of some strong ligands, there may be some re-arrangement of electrons in the atomic orbitals (against Hund's rule). The d-orbitals participating in this process of hybridization may be either (n-1)  $d^2sp^3$  or  $nsp^3d^2$ . The complexes thus formed are referred to as inner or low spin and outer or high spin complexes, respectively.
- (iv) The ligands have at least one  $\sigma$ -orbital containing a lone pair of electrons. Vacant hybrid orbitals of the metal atom or ion overlap with the  $\sigma$ -orbitals containing lone pair or electrons of the ligands to form  $M \leftarrow$  ligand  $\sigma$ -bond. This bond is called coordinate bond (a special type of covalent bond) and possesses a considerable amount of polarity.

(v) It is possible to predict the magnetic properties of the complex if the geometry of the complex ion (or *vice-versa*) is known. If the complex contains unpaired electrons, it is paramagnetic in nature whereas if it does not contain unpaired electrons, *i.e.*, all are paired, the complex is diamagnetic in nature. Complexes having unpaired electron are coloured.

The number of unpaired electrons and the geometries of the complex ions having central metal ion with configurations  $d^1$  to  $d^9$  are related to each other as shown below:

The shapes and magnetic nature of some of the common complexes of metals of 3d-series have been described on the basis of valence bond theory in the table given below:

	Number of unpaired electrons for different geometries					
$d^x$ Configuration	T. 4. 1. 1. (3)	S (1, 2)	Octahedral			
	Tetrahedral (sp <sup>3</sup> )	Square planar (dsp <sup>2</sup> )	Inner orbitals (d <sup>2</sup> sp <sup>3</sup> )	Outer orbitals $(sp^3d^2)$		
$d^1$	1	. 1	1	1		
$d^2$	2	2	2	2		
$d^3$	3	3	3	3		
$d^4$	4	4	2	4		
$d^{5}$		3	1	5		
$d^6$	4	2	0	4		
$d^7$	3	1	1	3		
			(Shifted to higher orbits)			
<i>d</i> <sup>8</sup>	2	0		2		
		×	(2 electrons shifted)			
$d^9$	1	1 .	1	1		
		(Shifted)	(3 electrons shifted)			

Limitations of valence bond theory: The valence bond theory was fairly successful in explaining qualitatively the geometry and magnetic properties of complexes. However, it has a number of limitations.

- (i) The theory does not offer any explanation about the spectra of complex (why most of the complexes are coloured).
- (ii) Sometimes the same metal ion assumes different geometry when formation of complex ion takes place. The theory is unable to explain why at one time the electrons are rearranged against the Hund's rule while at other times the electronic configuration is not disturbed.
  - (iii) The theory does not offer an explanation for the existence of inner-orbital and outer-orbital complexes.
  - (iv) The theory does not explain why certain complexes are labile while others are inert.
- (v) In the formation of  $[Cu(NH_3)_4]^{2+}$ , one electron is shifted from 3d to 4p-orbital. The theory is silent about the energy availability for shifting such an electron. Such an electron can be easily lost, then why  $[Cu(NH_3)_4]^{2+}$  complex does not show reducing properties.
  - (vi) The changes in energies of the metal orbitals on formation of complex are difficult to calculate mathematically.

<ol> <li>These complexes are formed by hybridization of d<sup>2</sup>sp<sup>3</sup> hybridisation.         These are formed by strong ligands.     </li> <li>These complexes generally possess less number of unpaired electrons i.e., they show either low or no magnetic moment.</li> <li>These are less reactive i.e., more stable. Substitution reactions are difficult to occur.</li> </ol>	<ol> <li>These complexes are formed by hybridisation of sp<sup>3</sup>d<sup>2</sup> hybridisation. These are formed by weak ligands.</li> <li>These complexes generally possess greater number of unpaired electrons i.e., they show high magnetic moment.</li> <li>These are reactive i.e., less stable. Substitution reactions are easy to occur.</li> </ol>		

Note: (i)  $M^{n+}$  ions which have one, two or three electrons in 3d orbitals prefer to form inner orbital octahedral complexes.

- (ii)  $M^{n+}$  ions which have  $d^8$  and  $d^9$  configurations prefer to form outer orbital octahedral complexes.
- (iii)  $M^{n+}$  ions which have  $d^4$ ,  $d^5$  and  $d^6$  configurations may form either inner or outer orbital complexes. It depends on the nature of the ligand.
- (iv) M<sup>n+</sup> (Pt<sup>2+</sup>, Pd<sup>2+</sup>, Ni<sup>2+</sup>, Au<sup>3+</sup>, etc.) having d<sup>8</sup> configuration mainly form square planar complexes.
- (v)  $M^{n+}$  having  $d^0$ ,  $d^5$  and  $d^{10}$  configurations prefer to form tetrahedral complexes.

#### (2) Crystal field theory

Crystal field theory was proposed by H. Bethe (1929) and Van Vleck (1932) and was originally applied to ionic crystals to explain their optical properties and is, therefore, called **crystal field theory**. However, this theory was applied to the study of coordination compounds in 1950. The valence bond theory represents the ligand metal bond as covalent, with an electron pair, shared between the metal and the ligand donor atom. The valence bond theory is frequently used but it is not adequate to explain properties of complexes such as colour and magnetism. Currently, the bonding in coordination complexes is usually described by crystal field theory or ligand field theory. This theory accounts for more satisfactory explanation for the properties of complexes especially colour and magnetism. The main points of the theory are:

(i) According to crystal field theory, the bonding in complex ions is purely electrostatic. This theory regards the ligand atoms of ionic ligands such as F<sup>-</sup>, Cl<sup>-</sup> or CN<sup>-</sup> as negative point charges (also called point charges) and if the ligand molecules are neutral, these are regarded as point dipoles or simply dipoles, the negative end pointing towards central metal ion.

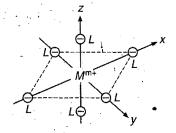

- (ii) The complex is regarded as a combination of a central metal ion surrounded by ligands which act as point charges or point dipoles. The arrangement of ligands around the central metal ion or atom is such that the repulsion between these negative points or dipoles is minimum.
- (iii) Interactions between positively charged nucleus of the central metal ion or atom and the negatively charged ligands are of two types:
- (a) The attractive forces arise due to the positive metal ion and the negatively charged ligands or the negative end of a polar neutral molecules. For example, in the case of complex ion,  $[Fe(CN)_6]^{3-}$ , the interactions are between  $Fe^{3+}$  ion and negatively charged  $CN^-$  ions whereas in the complex;  $[Cr(NH_3)_6]^{3+}$ , the interactions are between  $Cr^{3+}$ ion and

negatively charged ends of ammonia molecules. These attractive forces bind the ligands to the metal ion. The bonds between metal and the surrounding ligands are purely ionic. This theory does not consider any orbital overlapping.

- (b) The repulsive forces arise between the lone pairs on the ligands and electrons in the d-orbitals of the metal or atom. The crystal field theory mainly focuses on these repulsive forces. These forces are responsible for causing a considerable effect on the relative energies of the d-orbitals of the central metal ion or atom.
- (iv) In a free transition metal or ion, there are five d-orbitals which are designated as  $d_{xy}$ ,  $d_{yz}$ ,  $d_{zz}$ ,  $d_{x^2-y^2}$  and  $d_{z^2}$ . The five d-orbitals are divided into two sets depending on the nature of their orientation in space.
- (a) The three *d*-orbitals  $(d_{xy}, d_{yz}, d_{zx})$  which orient in the regions between the coordinate axes are designated as  $t_{2g}$  orbitals (pronounced as "t-two-g").  $t_{2g}$ -orbitals are three-fold degenerate. These are non-axial orbitals.
- (b) The other two orbitals  $(d_{\chi^2-\chi^2})$ ,  $d_{\chi^2}$  which orient along the axes are called  $e_g$ , orbitals (pronounced as "e-g").  $e_g$ , orbitals are two fold degenerate. These are also called axial-orbitals.

[The names  $t_{2g}$  and  $e_g$  are derived from spectroscopic terms.] In a free transition metal ion or atom, all the five d-orbitals have same energy, *i.e.*, they are degenerate. However, when the ligands approach the central metal ion or atom, the electrons of the d-orbitals of the central metal ion or atom are repelled by lone pairs of the ligands. As a result of these interactions, the degeneracy of d-orbitals of the metal ion is lost depending on the orientation of ligands in space. The d-orbitals split into two sets of orbitals having different energies. This is called crystals field splitting. It is the basis of crystal field theory. The extent of splitting depends on the number of ligands and their position around the metal atom or ion. The splitting is different in different structures with different coordination numbers.

**Splitting of** *d***-orbitals in octahedral complexes:** Let us consider an octahedral complex,  $[ML_6]^{n+}$ , in which the central metal ion is placed at the centre of the octahedron and is surrounded by six ligands which reside at the six corners of the octahedron as shown below.

The electrons in d-orbitals of the metal cation are repelled by negative point charge or by the negative end of the dipole of the ligands. This repulsion increases the energy of all the five d-orbitals. If all the ligands approaching the metal cation are at an equal distance from each of d-orbitals (i.e., the ligand field is spherically symmetrical), the energy of each of the five

d-orbitals increases by the same amount, *i.e.*, all the d-orbitals remain degenerate, although they possess higher energy. However, this is not possible as it is only hypothetical situation.

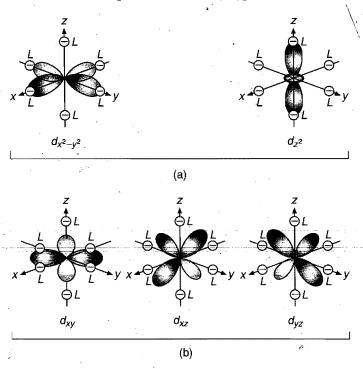

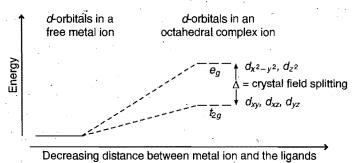

Fig. 15.1 The shapes of the five *d*-orbitals and their orientations with respect to an octahedral array of charged ligands

As the lobes of the  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals [Fig. 15.1(a)] point directly towards the ligands, an electron in either of these orbitals is nearer to the electron pairs of the ligands than if it was in a  $d_{xy}$ ,  $d_{xz}$  or  $d_{yz}$  orbitals, with lobes pointing between the ligands [Fig. 15.1(b)]. Thus, the repulsions between the ligands and the  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals are greater than the repulsions between the ligands and  $d_{xy}$ ,  $d_{xz}$  and  $d_{yz}$  orbitals. Consequently, the energies of  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals are

**Fig. 15.2 (i)** The changes in the energies of the *d*-orbitals of a metal ion as an octahedral complex is formed. As the ligands approach the metal ion, the initially degenerate *d*-orbitals split into two new sets of degenerate orbitals.

higher than the energies of  $d_{xy}$ ,  $d_{xz}$  and  $d_{yz}$  orbitals. Therefore, it is clear that introduction of the ligands removes the degeneracy of the five d-orbitals, splitting them into two sets of degenerate orbitals; the lower energy set consists of the  $d_{xy}$ ,  $d_{xz}$  and  $d_{yz}$  orbitals and higher energy set comprises the  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals [Fig. 15.2 (i)]. The three lower energy orbitals are collectively called the  $t_{2g}$  orbitals while the two higher energy orbitals are called  $e_g$  orbitals.

Thus, an energy difference exists between two sets of orbitals. This energy difference is called **crystal field splitting energy** (CFSE) or **crystal field stabilization energy** and is

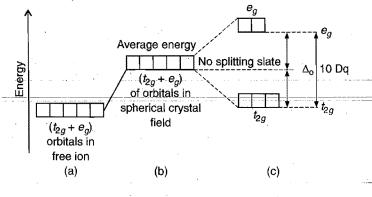

Fig. 15.2 (ii) Crystal field splitting of d-orbitals in an octahedral complex (a) Five degenerate d-orbitals of free metal cation

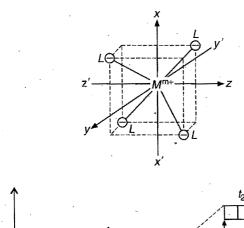

- (b) Hypothetical degenerate *d*-orbitals at higher energy level under spherically symmetrical ligand field
- (c) Splitting of d-orbitals under the influence of ligands.

represented by  $\Delta_o$  (the subscript o stands for octahedral). It measures the crystal field strength of the ligands. The crystal field splitting occurs in such a way that average energy of the d-orbitals does not change.

Thus, three orbitals lie at an energy that is  $-\frac{2}{5}\Delta_0$  below the average d-orbital energy and two d-orbitals lie at an energy  $+\frac{3}{5}\Delta_0$  above the average energy. The energy gap between  $t_{2g}$  and  $e_g$  sets is also denoted by 10 Dq. Energy of  $t_{2g}$  orbitals is 4 Dq less than that of hypothetical degenerate d-orbitals and that of  $e_g$  orbitals is 6 Dq above that of the hypothetical degenerate d-orbitals. Thus,  $t_{2g}$  set loses an energy equal to -0.4  $\Delta_0$  or -4 Dq while  $e_g$  set gains an energy equal to +0.6  $\Delta_0$  or +6 Dq.

Crystal field splitting in tetrahedral complexes: The tetrahedral arrangement of four ligands surrounding the metal ion  $M^{m+}$  may be depicted as shown in Fig. 15.3.

The three *d*-orbitals, *i.e.*,  $t_{2g}$  orbitals are close to the approaching ligands. As a result of this, the  $t_{2g}$  electrons suffer more repulsion than  $e_g$  electrons. The energy of  $t_{2g}$  orbitals increases more than  $e_g$  orbitals. The splitting is shown in Fig. 15.3.

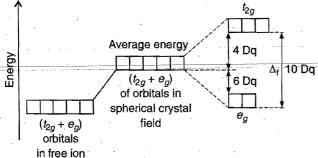

Fig. 15.3 Crystal field splitting of d-orbitals in a tetrahedral complex

The energy gap between two sets of orbitals is designated as  $\Delta_t$  (The subscript t indicates tetrahedral complex). It is observed that  $\Delta_t$  is considerably less than  $\Delta_0$ . It has been found that,

$$\Delta_t = \frac{4}{9} \Delta_0$$

Crystal field splitting in square planar complexes: The square planar arrangement of four ligands surrounding the metal ion may be considered as derived from octahedral by removing two ligands from z-axis. On account of removing negative charges from z-axis,  $d_{z^2}$ ,  $d_{xz}$  and  $d_{yz}$  orbitals having z-component become more stable. As the lobes of  $d_{x^2-y^2}$  point towards the ligands, the orbital has highest energy and the lobes of  $d_{xy}$  orbital lie between the ligands, it is thus next highest in energy. The lobes of  $d_{xz}$  and  $d_{yz}$  are least affected by electrostatic field of the ligands as they lie out of the plane

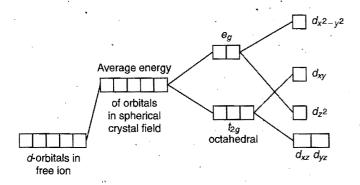

Fig. 15.4 Splitting of d-orbitals in square planar complex

of the complex. The lobes of  $d_{z^2}$  orbital lie out of the plane but the belt around the centre of the orbital lies in the plane of the complex is somewhat affected by electrostatic field of the ligands. The splitting of d-orbitals in square planar complex can be depicted as shown in Fig. 15.4.

Spectrochemical series: For any given metal cation, the magnitude of crystal field splitting energy depends on the nature of the ligands. The greater the ease with which the ligand can approach the metal ion, the greater will be the crystal field splitting caused by it. The ligands which affect only a small degree of crystal field splitting are termed weak field ligands while those which affect a large splitting are called strong field ligands.

When the ligands are arranged in order of the magnitude of crystal field splitting, the arrangement, thus, obtained is called spectrochemical series.

$$I < Br < CI < NO_3 < F < OH < OX^2 < H_2O < py$$
Weak field ligands

Increasing crystal field

 $I = NH_2 < en < dipy < c_Phen < NO_3 < CN < CO_3$ 

$$= NH_3 < en < dipy < o-Phen < NO_2 < CN < CO$$
Strong field ligands

From the above arrangement it is clear that ligands before  $H_2O$  such as  $I^-$ ,  $NO_3^-$ ,  $OH^-$ , etc., are weak field ligands while the ligands after  $H_2O$  such as  $NO_2^-$ ,  $CN^-$ , CO, etc., are strong field ligands. Stronger field ligands cause greater crystal splitting *i.e.*,  $\Delta_0$  value for octahedral complex is high.

Besides the nature of ligands, there are some other factors which affect the crystal field splitting energy. These factors are:

- (i) The position of transition metal in the periodic table: The magnitude of  $\Delta_0$  increases in going down a group, i.e., an ion of an element in the first transition series has a smaller value of  $\Delta_0$  than the ion of a heavier member of the same group. Thus, comparing complexes of  $\mathrm{Ni}^{2+}$  and  $\mathrm{Pt}^{2+}$  with the same ligand, it is observed that platinum complexes have larger crystal field splitting. The crystal field splitting,  $\Delta_{\overline{0}}$ , is about 50% higher for second transition series compared to the first whereas the third series in about 25% higher than second. There is small increase in the crystal field splitting along each series.
- (ii) The oxidation state of the metal: Generally, the higher the oxidation state of the metal, the greater the crystal field splitting. For example, most of the cobalt (II) complexes have low values of  $\Delta$  whereas all cobalt (III) complexes have high values of  $\Delta$ .
- (iii) The number of ligands: The crystal field splitting for a tetrahedral environment is about 4/9 that for an octahedral environment.

**Distribution of** d**-electrons in**  $t_{2g}$  **and**  $e_g$  **orbitals in octahedral complexes:** The distribution of d-electrons in  $t_{2g}$  and  $e_g$  orbitals takes place on the basis of the nature of ligands. Two cases may arise.

when the ligands are weak: Under the influence of weak ligands, the energy difference,  $\Delta_0$ , between  $t_{2g}$  and  $e_g$  sets is relatively small and hence all the five d-orbitals may be supposed to be degenerate, *i.e.*, all the d-orbitals have nearly the same energy and the distribution of electrons in  $t_{2g}$  and  $e_g$  sets occurs according to Hund's rule, *i.e.*, electrons will pair up only when each of the five d-orbitals is at least singly occupied. When the ligands are weak, the first three electrons numbered 1, 2, 3 go to  $t_{2g}$  set, those numbered 4, 5 go to  $e_g$  set, those numbered 6, 7, 8 go to  $t_{2g}$  set and the remaining two electrons numbered 9, 10 will occupy  $e_g$  set. This can be shown as:

$$t_{2g}^{1, 2, 3} \longrightarrow e_g^{4, 5} \longrightarrow t_{2g}^{6, 7, 8} \longrightarrow e_g^{9, 10}$$

In complexes of weak ligands,  $\Delta_0$  is less than P (P is called average pairing energy which is the energy required to pair two electrons in the same orbital).  $\Delta_0$ , the octahedral crystal field splitting energy, tends to force as many electrons to  $t_{2g}$  set while P tends to prevent the electrons to pair in the  $t_{2g}$  level.

(ii) When the ligands are strong: Under the influence of strong ligands, the energy difference between  $t_{2g}$  and  $e_g$  sets is relatively high and thus the distribution of d electrons in  $t_{2g}$  and  $e_g$  sets does not obey Hund's rule. The first electrons numbered 1, 2, 3, 4, 5, 6 will go to  $t_{2g}$  set and remaining four electrons numbered 7, 8, 9 and 10 will go to  $e_g$  set.

$$t_{2g}^{1, 2, 3, 4, 5, 6} \longrightarrow e_g^{7, 8, 9, 10}$$

For these complexes,  $\Delta_0$  is higher than P. The above points are summarised in the following table:

χι	Strong field (Low spin) complexes $\Delta_0 > P$			Weak field (High spin) complexes $\Delta_0 < P$			Common
d ions	Config- uration	1		Config- uration		Spin	examples
$d^1$	$t_{2g}^1$ . $e_g^0$	1	1/2	$t_{2g}^1 e_g^0$	1	1/2	Ti <sup>3+</sup>
$d^1$ $d^2$	$\begin{array}{c} t_{2g}^{1}.e_{g}^{0} \\ t_{2g}^{2}.e_{g}^{0} \end{array}$	2	1	$t_{2g}^2 e_g^0$	2	1	V <sup>3+</sup>
$d^3$ .	$t_{2g}^3 e_g^0$	3	3/2	$t_{2g}^3 e_g^0$	3	3/2	Ti <sup>3+</sup> V <sup>3+</sup> Cr <sup>3+</sup>
$d^4$	$\begin{array}{cccc} t_{2g}^4 & e_g^0 \\ t_{2g}^5 & e_g^0 \\ t_{2g}^6 & e_g^0 \end{array}$	2 .	1	$t_{2g}^3 e_g^1$	4	2	Mn <sup>3+</sup>
$d^5$	$t_{2g}^5$ , $e_g^0$	1 .	1/2	$t_{2g}^3 e_g^2$	5	5/2	Mn <sup>2+</sup> ,Fe <sup>3+</sup>
$d^6$	$t_{2g}^6 e_g^0$	0	0	$t_{2g}^4 e_g^2$	4	2	Fe <sup>2+</sup> ,Co <sup>3+</sup>
$d^7$	$t_{2g}^6 e_g^1$	1	1/2	$t_{2g}^5 e_g^2$	3	3/2	Co <sup>2+</sup>
$d^8$		2	1	$t_{2g}^6 e_g^2$	2	1	Ni <sup>2+</sup>
$d^9$	$\begin{array}{c cccc} & t_{2g}^6 & e_g^2 \\ & t_{2g}^6 & e_g^3 \end{array}$	1	1/2	$t_{2g}^6 e_g^3$	1	1/2	Cu <sup>2+</sup> Zn <sup>2+</sup>
$d^{10}$	$t_{2g}^6 e_g^4$	0	0	$t_{2g}^6 e_g^4$	0	0	Zn <sup>2+</sup>

The following conclusions are derived from the table:

(i) The distribution of electrons of  $d^1$ ,  $d^2$ ,  $d^3$ ,  $d^8$ ,  $d^9$  and  $d^{10}$  in  $t_{2g}$  and  $e_g$  sets for both strong and weak octahedral ligands fields is the same.

- (ii) For each of  $d^4$ ,  $d^5$ ,  $d^6$  and  $d^7$  there is difference in the arrangement of electrons in weak and strong ligands field.
- (iii) Weak field complexes of  $d^4$ ,  $d^5$ ,  $d^6$  and  $d^7$  ions have greater number of unpaired electrons than those of strong field complexes and thus, the resultant spins of weak field complexes have higher value than strong field complexes.

Hence, the complexes of weak field ligands are called **high** spin complexes and the complexes of strong field ligands are called **low spin complexes**.

### Calculation of CFSE

Each electron occupying  $t_{2g}$  orbital results in lowering of energy by  $-0.40~\Delta_0$  (or  $-4~\mathrm{Dq}$ ). Similarly, each electron occupying  $e_g$  orbital results in increase of energy by  $+0.60~\Delta_0$  (or  $+6~\mathrm{Dq}$ ). Thus,

CFSE = 
$$(-0.4x + 0.6y) \Delta_0$$

where, x = number of electrons occupying  $t_{2g}$  orbitals and y = number of electrons occupying  $e_g$  orbitals. Negative value of CFSE indicates net lowering in energy, i.e., gain in stability.

Calculation of CFSE Values for  $d^1$  to  $d^{10}$ Configurations

Metal ion Confi- guration	Low spin state (strong ligand field)	CFSE (Δ <sub>o</sub> )	High spin state (weak ligand field)	CFSE (Δ <sub>0</sub> )
$d^1$	$t_{2g}^1 e_g^0$	$-0.4 \times 1$ = -0.4 or -4 Dq	$t_{2g}^1 e_g^0$	$-0.4 \times 1$ = -0.4 or -4 Dq
$d^2$	$t_{2g}^2 e_g^0$	$-0.4 \times 2$ = -0.8 or -8 Dq	$t_{2g}^2 e_g^0$	$-0.4 \times 2$ = -0.8 or -8 Dq
$d^3$	$t_{2g}^3 e_g^0$	-0.4 × 3	$t_{2g}^3 e_g^0$	-0.4 × 3
$d^4$	$t_{2g}^4 e_g^0$	= -1.2  or  -12  Dq $-0.4 \times 4$	$t_{2g}^3 e_g^1$	= -1.2  or  -12  Dq $-0.4 \times 3 + 0.6$
$d^5$	$t_{2g}^5 e_g^0$	= -1.6  or  -16  Dq $-0.4 \times 5$	$t_{2g}^3 e_g^2$	= -0.6 or 6 Dq $-0.4 \times 3 + 2 \times 0.6$
d 6	$t_{2g}^6 e_g^0$	= -2.0  or  -20  Dq $-0.4 \times 6$	$t_{2g}^4 e_g^2$	$= 0.0 \text{ or } 0 \text{ Dq}$ $-0.4 \times 4 + 2 \times 0.6$
$d^{7}$	$t_{2g}^6 e_g^1$	= -2.4  or  -24  Dq $-0.4 \times 6 + 0.6$	$t_{2g}^5 e_g^2$	= -0.4 or 4 Dq $-0.4 \times 5 + 2 \times 0.6$
$d^8$	$t_{2g}^6 e_g^2$ .	$= -1.8 \text{ or } -18 \text{ Dq}$ $-0.4 \times 6 + 2 \times 0.6$	$t_{2g}^6 e_g^2$	= -0.8 or 8 Dq $-0.4 \times 6 + 2 \times 0.6$
d 9	$t_{2g}^6 e_g^3$	= -1.2  or  -12  Dq $-0.4 \times 6 + 3 \times 0.6$	$t_{2g}^{6} e_{g}^{3}$	= -1.2  or  -12  Dq $-0.4 \times 6 + 3 \times 0.6$
$d^{10}$	$t_{2g}^6 e_g^4$	$= -0.6 \text{ or } -6 \text{ Dq}$ $-0.4 \times 6 + 4 \times 0.6$ $= 0.0 \text{ or } 0 \text{ Dq}$	$t_{2g}^6 e_g^4$	= -0.6  or  -6  Dq $-0.4 \times 6 + 4 \times 0.6$ = 0.0  or  0  Dq

The above calculations show that coordination entities with four to seven *d*-electrons are more stable for strong ligand field as compared to weak ligand field.

Distribution of d-electrons in  $t_{2g}$  and  $e_g$  orbitals in tetrahedral complexes: The distribution of d-electrons in the  $t_{2g}$  and  $e_g$  sets in a tetrahedral complex in presence of weak and strong ligands field has been shown in the following table:

, X		eld (High sp omplexes	pin)	Strong field (Low spin) complexes			
d ions	Config- uration	No. of unpaired electrons	Spin	Config- uration	No. of unpaired electrons	Spin	
$d^{1}$	$t_{2g}^0 e_g^1$	. 1	1/2	$t_{2g}^0 e_g^1$	1	1/2	
$\frac{d^1}{d^2}$	$\begin{array}{cccc} t_{2g}^{0} & e_{g}^{1} \\ t_{2g}^{0} & e_{g}^{2} \end{array}$	2	1	$\begin{array}{ccc} t_{2g}^{0} & e_{g}^{1} \\ t_{2g}^{0} & e_{g}^{2} \end{array}$	2	1	
$d^3$ $d^4$	$t_{2g}^{1} e_{g}^{2}$	3	$1\frac{1}{2}$	$t_{2g}^{0} e_{g}^{3}$	1	1/2	
$d^{4}$	$\begin{array}{c ccccccccccccccccccccccccccccccccccc$	4	2	$-t_{2g}^{0} e_{g}^{4}$	0	0	
$-d^5$	$=t_{2g}^{3}-e_{g}^{2}$	55	$\frac{1}{2}$	$t_{2g}^1$ $e_g^4$		1/2	
$d^6$	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	. 4	2	$t_{2g}^2 e_g^4$	2	. 1	
$\frac{d^7}{d^8}$	$t_{2g}^3$ $e_g^4$	3.	$1\frac{1}{2}$	$t_{2g}^3 e_g^4$	3	$1\frac{1}{2}$	
$d^8$	$t_{2p}^{4} e_{p}^{4}$	2	1	$t_{2g}^4 e_g^4$	2	1	
<b>d</b>	$t_{2g}^{5}.e_{g}^{4}$	11	1/2	$t_{2g}^{5} e_{g}^{4}$	11	1/2	
$d^{10}$	$t_{2g}^{5} e_{g}^{4}$ $t_{2g}^{6} e_{g}^{4}$	0	0	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	0	0	

Magnetic nature: The transition metal complexes containing one or more unpaired electrons possess a definite value of magnetic moment. An unpaired electron because of its spin is equivalent to an electric current flowing in a circular conductor. Hence, it behaves as a magnet.

[The magnetic moment is expressed as :

$$\mu = \frac{eh}{4\pi mc} = 9.274 \times 10^{-21} \text{ erg gauss}^{-1}$$
= one Bohr Magneton (B.M.)

where, e = charge on electron; m = mass of electron;

h = Planck's constant; c = velocity of light

The substances having magnetic moments are attracted in external magnetic field. Such substances are termed paramagnetic substances. Most of the coordination compounds are paramagnetic. The substances having no unpaired electron or having only paired electrons show zero magnetic moment and are called diamagnetic substances.

The magnetic nature or magnetic moment of a coordination compound, thus, depends on the number of unpaired electrons. The magnetic moment is approximately given by the relation,

Magnetic moment,  $\mu = \sqrt{n(n+2)}$  B.M., where n is the number of unpaired electrons. This relationship is used to calculate the number of unpaired electrons in a complex ion. The values of n calculated by applying the above formula for different magnetic moments are given in the following table:

Magnetic moment (B.M.)	Number of unpaired electrons
1.73	1
2.83	2
3.87	3
4.90	4 .
5.92	5

The actual number of unpaired electrons in a complex can be found by magnetic measurements and in general, experimental findings support predictions based on crystal field splitting. However, a distinction between low and high spin complexes can be made only if the metal ion contains more than three and less than eight d-electrons. The high spin complex,  $[Fe(H_2O)_6]^{2+}$  has four unpaired electrons and is **paramagnetic** whereas the low spin complex,  $[Fe(CN)_6]^{4-}$  has no unpaired electrons and is **diamagnetic**.

Colour: A substance appears coloured because it absorbs light at specific wavelengths in the visible part of the electromagnetic spectrum (400 to 700 nm) and transmits or reflects the rest of the wavelength. Each wavelength of visible light represents a different colour. White light, such as sunlight, is a combination of all colours; an object that absorbs all visible light appears black. The following table shows the relationship of wavelength absorbed to observed colour.

When the energy of the photon (hv) is equal to the difference between the lower and higher d-orbital energy levels, an electron is promoted from a lower to higher level. If the wavelength of the photon absorbed by an ion lies outside the visible region, then the transmitted light looks the same as the incident light white and the ion appears colourless.

Spectroscopic analysis offers the best means of measuring crystal field splitting. The  $[Ti(H_2O)_6]^{3+}$  ion provides a simple example, because  $Ti^{3+}$  has only one 3 *d*-electron.  $[Ti(H_2O)_6]^{3+}$  ion absorbs light in the visible region. The wavelength corresponding to maximum absorption is 498 nm. This enables us to calculate the crystal field splitting.

$$\Delta = hv = h \times \frac{c}{\lambda}$$
where  $h = \text{Planck's constant} = 6.63 \times 10^{-34} \text{ Js}$ 
and  $c = \text{velocity of light} = 3.00 \times 10^8 \text{ ms}^{-1}$ 

$$= \frac{(6.63 \times 10^{-34}) \times (3.00 \times 10^8)}{498 \times 10^{-9}}$$

$$= 3.99 \times 10^{-19} \text{ J}$$

This is the energy for one ion to excite. Thus, the energy required for one mole of ions,

$$\Delta = 3.99 \times 10^{-19} \times 6.02 \times 10^{23}$$
  
= 240,000 J mol<sup>-1</sup> = 240 kJ mol<sup>-1</sup>

Photon of energy 
$$hv$$
  $d_{x^2-y^2}$   $d_{z^2}$   $d_{z^2-y^2}$   $d_{z^2}$ 

Experiments with coordination complexes have revealed that for a given metal ion, some ligands cause a small energy separation of the *d*-orbitals, whereas others cause a large separation, *i.e.*, different ligands may bring different colours to the complex ions of the same metal ion. For example, the data for several cobalt, (III) complexes are presented in the following table:

The colours of some complexes of Co<sup>3+</sup> ion

Complex ion	Wavelength of light absorbed (nm)	Colour of light absorbed	Colour of complex observed
$[Co(F)_6]^{3-}$	700	Red	Green
$[Co(C_2O_4)_3]^{3-}$	600	Yellow	Dark green
$[Co(H_2O)_6]^{3+}$	600	Yellow	Blue-green
$[Co(NH_3)_6]^{3+}$	475	Blue	Yellow-orange
$[Co(en)_3]^{3+}$	470.	Blue	Yellow-orange
$\left[\text{Co}(\text{CN})_6\right]^{3-}$	310	Ultraviolet	Pale-yellow

The absorption maxima among the listed complexes ranges from 700 nm for  $[\mathrm{CoF}_6]^{3-}$  to 310 nm for  $[\mathrm{Co}(\mathrm{CN})_6]^{3-}$ . The ligands change from member to member in the series and is concluded that the energy of light absorbed by the complex is related to different crystal field splitting,  $\Delta_0$ , caused by different ligands. Fluoride ion causes the smallest splitting of the d-orbitals among the complexes listed, whereas cyanide caused the largest splitting.

Spectra of complexes of other metals provide similar results. This supports the spectrochemical series. The ability of crystal field theory to explain differences in the colour of transition metal complexes is one of the strengths of this theory.

# 15.7 STABILITY OF COORDINATION COMPOUNDS IN SOLUTIONS

A coordination compound is formed in solution by the stepwise addition of ligands to a metal ion. Thus, the formation of the complex,  $ML_n$  (M = central metal cation, L = monodentate ligand and n = coordination number of metal ion) may be supposed to take place by the following n consecutive steps.

$$M + L \Longrightarrow ML$$

$$K_1 = \frac{[ML]}{[M][L]}$$

$$ML + L \Longrightarrow ML_2$$

$$K_2 = \frac{[ML_2]}{[ML][L]}$$

$$ML_2 + L \Longrightarrow ML_3$$

$$K_3 = \frac{[ML_3]}{[ML_2][L]}$$
...
...
$$ML_{n-1} + L \Longrightarrow ML_n$$

$$K_n = \frac{[ML_n]}{[ML_{n-1}][L]}$$

 $K_1, K_2, K_3, \ldots, K_n$  are called stepwise stability constants. With a few exceptions, the values of successive stability constants decrease regularly from  $K_1$  to  $K_n$ .

The overall stability constant, K, is given as:

$$M + nL \implies ML_n$$

$$K = K_1, K_2, K_3, \ldots, K_n = \frac{[ML_n]}{[M][L]^n}$$

The higher the overall stability constant value of the complex, the more stable it is. Alternatively, 1/K values called **instability constant** explain the dissociation of the complex into metal ion and ligands in the solution.

The values of stability constants for some of the complexes are given below:

Complex	Stability constant
$[Cu(NH_3)_4]^{2+}$	$4.5\times10^{11}$
$[Ag(NH_3)_2]^+$	$1.6 \times 10^7$
$[Co(NH_3)_6]^{2+}$	$1.12\times10^6$
$[Co(NH_3)_6]^{3+}$	$5.0\times10^{33}$
[AgCl <sub>2</sub> ]	$1.11\times10^5$
[AgBr <sub>2</sub> ]	$1.28 \times 10^{7}$
$[Ag(CN)_2]^-$	$1.0 \times 10^{22}$
$\left[\mathrm{Cu}(\mathrm{CN})_4\right]^{2-}$	$2.0 \times 10^{27}$
$[Fe(CN)_6]^{3-}$	$7.69 \times 10^{43}$

From the above values, some conclusions are drawn:

(i) The values of stability constants differ widely depending on the nature of the metal ion and the ligand. In general, higher the charge density on the central ion, the greater is the stability of its complexes, *i.e.*, the higher value of

charge radius of the ion, the greater is the stability of its complexes. Electronegativity of the central ion influences the

stability. The higher the electronegativity of the central ion, the greater is the stability of its complexes.

The more basic a ligand, the greater is the ease with which it can donate its lone pairs of electrons and therefore, the greater is the stability of the complexes formed by it.

- (ii) The higher the oxidation state of the metal, the more stable is the complex. The charge density of  $\operatorname{Co}^{3+}$  ion is more than  $\operatorname{Co}^{2+}$  ion and thus,  $[\operatorname{Co}(\operatorname{NH}_3)_6]^{3+}$  is more stable than  $[\operatorname{Co}(\operatorname{NH}_3)_6]^{2+}$ . Similarly,  $[\operatorname{Fe}(\operatorname{CN})_6]^{3-}$  is more stable than  $[\operatorname{Fe}(\operatorname{CN})_6]^{4-}$ .
- (iii) The cyano and ammine complexes are far more stable than those formed by halide ions. This is due to the fact that  $NH_3$  and  $CN^-$  are strong Lewis bases.
- (iv) The complexes of bivalent cations  $(M^{2+})$  of 3*d*-series show the following order of stability:

	*			-	
Cation	Mn <sup>2+</sup>	Fe <sup>2+</sup>	Co <sup>2+</sup>	Ni <sup>2+</sup>	Cu <sup>2+</sup>
Ionic size	0.91	0.83	0.82	0.78	0.69
			decrease	s	
Stability of the complex			increase	S	
		(Irving	William	order)	<del></del>

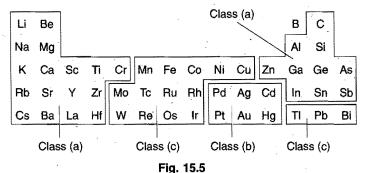

(v) Chelating ligands form more stable complexes as compared to monodentate ligands. Greater is the chelation, more is the stability of complex.

$$[Cr(NH_3)_6]^{3+}$$
 <  $[Cr(en)(NH_3)_4]^{3+}$  <  $[Cr(en)_2(NH_3)_2]^{3+}$  <  $[Cr(en)_3]^{3+}$ 

(vi) Thermodynamic stabilities of the complexes formed by various metals follow some regular trends, such as those involving size and charge effects, factors that determine the Lewis acid strength of a metal ion.

Generally, the stabilities of complexes decrease with increasing atomic number for the electropositive metals *e.g.*, group IIA or hard Lewis acids and increase with increasing atomic number for the noble metals (soft acids), following the general trend of ionization energy.

- (a) For the electropositive metals (hard acids) the order of stabilities of halide complexes is F > Cl > Br > I but for highly polarizing soft acid metal ions such as  $Hg^{2+}$ , we see reverse order.
- (b) The most electropositive metals (hardest acids) show a greater tendency for forming complexes with hard ligands such as F or oxygen containing ligands.

Metals are classified according to their acceptor properties.

Class (a)  $\longrightarrow$  **Hard acids :** Show affinities for the ligands whose basicity is proportional to protons.

Class (b) — Soft acids: form stable olefin complexes

Class (c)  $\longrightarrow$  Border line metals.

# 15.8 PREPARATION OF COORDINATION COMPOUNDS

Coordination compounds are generally prepared by the application of the following methods:

1. Ligand substitution reactions: A reaction involving the replacement of the ligands attached to the central metal ion in the complex by other ligands is called a ligand substitution reaction. Transition metal ions in aqueous solution form complex ions by bonding with water molecules. These water molecules are then replaced by ligands to form the desired complex.

$$\begin{aligned} & [\text{Cu}(\text{H}_2\text{O})_4]^{2+}(aq.) + 4\text{NH}_3(aq.) \rightarrow & [\text{Cu}(\text{NH}_3)_4]^{2+}(aq.) + 4\text{H}_2\text{O}(l) \\ & \text{(Light blue)} \end{aligned}$$

$$[\text{Ni}(\text{H}_2\text{O})_6]^{2+}(aq.) + 6\text{NH}_3(aq.) \rightarrow [\text{Ni}(\text{NH}_3)_6]^{2+}(aq.) + 6\text{H}_2\text{O}(l)$$
(Green) (Blue-violet)

$$[\text{Ni}(\text{NH}_3)_6]^{2+}(aq.)+4\text{CN}^-(aq.)\rightarrow [\text{Ni}(\text{CN})_4]^{2-}(aq.)+6\text{NH}_3(aq.)$$
(Yellow)

- *i.e.*, tetraamminecopper sulphate, [Cu(NH<sub>3</sub>)<sub>4</sub>]SO<sub>4</sub>, is formed by addition of ammonia solution to copper sulphate solution and potassium tetracyanonickelate(II) is obtained by the addition of potassium cyanide solution to hexaamminenickel(II) sulphate solution.
- **2. Direct mixing of reagent:** Dichloro *bis* (ethylenediamine) platinum(II) is prepared by adding platinum chloride (PtCl<sub>2</sub>) to ethylenediamine.

$$PtCl2 + 2H2N - CH2 - CH2 - NH2 - M2 - Pt(en)2Cl2$$
(en)

Similarly, hexaamminenickel(II) chloride is obtained by direct reaction between solid nickel chloride (NiCl<sub>2</sub>) and liquid ammonia.

$$NiCl_2 + 6NH_3(l) \longrightarrow [Ni(NH_3)_6]Cl_2$$

3. Redox reactions: In these reactions, either oxidation or reduction is involved. Cobalt(II) nitrate reacts with aqueous ammonium nitrate and aqueous ammonia in presence of  $H_2O_2$  (oxidising agent) to form pentaamminenitrocobalt(III) nitrate.

$$2\text{Co(NO}_3)_2 + 8\text{NH}_3 + 2\text{NH}_4\text{NO}_3 + \text{H}_2\text{O}_2 \longrightarrow$$
  
 $2[\text{Co(NH}_3)_5\text{NO}_2](\text{NO}_3)_2 + 2\text{H}_2\text{O}_3$ 

# 15.9 IMPORTANCE OF COORDINATION COMPOUNDS

The complexes are of immense importance on account of their applications in various fields. During complex formation there are drastic changes in the properties of metal atom or ion and these changes in properties are made use of in the applications of metal complexes.

## 1. Analytical chemistry

Coordination compounds find their applications in both qualitative and quantitative methods of analysis.

(a) The separation of Ag<sup>+</sup> from Hg<sub>2</sub><sup>2+</sup> in the first group of analysis is based on the fact that while silver chloride is soluble in aqueous ammonia and Hg<sub>2</sub>Cl<sub>2</sub> forms a black insoluble material.

$$\begin{array}{c} AgCl + 2NH_4OH \longrightarrow [Ag(NH_3)_2]Cl + 2H_2O \\ \\ Soluble \\ Hg_2Cl_2 + NH_4OH \longrightarrow \underbrace{Hg(NH_2)Cl + Hg + HCl + H_2O}_{Pl_1+Pl_2} \end{array}$$

(b) The separation of II B group sulphides from II A group sulphides is based on the fact that sulphides of II B group form complex sulphides with yellow ammonium sulphide which are soluble while sulphides of II A group do not react.

$$Sb_2S_5 + 3(NH_4)_2S \longrightarrow 2(NH_4)_3[SbS_4]$$

$$As_2S_5 + 3(NH_4)_2S \longrightarrow 2(NH_4)_3[AsS_4]$$

$$SnS_2 + (NH_4)_2S \longrightarrow (NH_4)_2[SnS_3]$$

(c) The detection of Cu<sup>2+</sup> is based on the formation of a blue tetraammine copper sulphate complex which gives a deep blue coloured solution.

$$CuSO_4 + 4NH_3 \longrightarrow [Cu(NH_3)_4]SO_4$$

It also forms a chocolate coloured precipitate with potassium ferrocyanide.

$$2CuSO_4 + K_4Fe(CN)_6 \longrightarrow Cu_2[Fe(CN)_6] + 2K_2SO_4$$
Chocolate ppt.

(d) Fe<sup>3+</sup> is detected by formation of a blood red coloured complex with KSCN.

$$Fe^{3+} + KSCN \longrightarrow [Fe(SCN)]^{2+} + K^{+}$$
Blood red colour

(e) The detection and estimation of Ni<sup>2+</sup> is based on the formation of a scarlet red complex with dimethyl glyoxime.

$$CH_{3}-C=NOH$$

$$NiCl_{2}+2 \qquad | \qquad +2NH_{4}OH \longrightarrow$$

$$CH_{3}-C=NOH$$

$$OH \qquad 0$$

$$CH_{3}-C=N \qquad N=C-CH_{3}$$

$$CH_{3}-C=N \qquad N=C-CH_{3}$$

$$CH_{3}-C=N \qquad N=C-CH_{3}$$

$$O \qquad OH$$

Scarlet red precipitate

(f) Many ligands (organic reagents) are used for the gravimetric estimation of a number of metal ions.

Metal ion to be estimated	Organic reagent used
Cu <sup>2+</sup>	Benzoin oxime
Ni <sup>2+</sup>	Dimethyl glyoxime
Fe <sup>3+</sup>	1, 10-phenanthroline
A1 <sup>3+.</sup>	8-hydroxyquinoline
Co <sup>2+</sup>	α-nitroso β-naphthol

- (g) EDTA is used as a complexing agent in volumetric analysis of metal ions like Ca<sup>2+</sup>, Mg<sup>2+</sup> and Zn<sup>2+</sup>.
- (h) The coordination compounds of the transition metals exhibit a variety of colours. This property is utilised in colorimetric analysis for the estimation of many metals.
- (i) Other analytical applications of coordination compounds are oxidation-reduction indicators, estimation of hardness in water, sequestering reagents and solvent extraction.

### 2. Metallurgical operations

Silver and gold are extracted by the use of complex formation. Silver ore is treated with sodium cyanide solution with continuous passing of air through solution. Silver dissolves as a cyanide complex and pure silver is precipitated by the addition of scrap zinc.

$$Ag_2S + 4NaCN \implies 2Na[Ag(CN)_2] + Na_2S$$

$$4Na_2S + 5O_2 + 2H_2O \longrightarrow 2Na_2SO_4 + 4NaOH + 2S$$

$$2Na[Ag(CN)_2] + Zn \longrightarrow Na_2[Zn(CN)_4] + 2Ag$$

Native Ag and Au also dissolve in NaCN solution in presence of oxygen of the air.

$$4 Ag + 8 NaCN + O_2 + 2 H_2O \longrightarrow 4 Na[Ag(CN)_2] + 4 NaOH$$

Ag and Au are precipitated by addition of scrap zinc.

Nickel is extracted by converting it into a volatile complex, nickel carbonyl by use of carbon monoxide (Mond's process). The complex decomposes on heating again into nickel and carbon monoxide.

$$Ni + 4CO \longrightarrow Ni(CO)_4 \xrightarrow{Heating} Ni + 4CO$$
(Associated with other metals)

# 3. Photography

In photography, the image on the negative is fixed by dissolving all the remaining silver halides with hypo solution in the form of a soluble complex.

$$AgBr + 2Na_2S_2O_3 \longrightarrow Na_3[Ag(S_2O_3)_2] + NaBr$$
(Soluble) (Soluble)

## 4. Electroplating

Metal complexes release metal slowly and thus give a uniform coating in electroplating of the metal on the desired object. Cyano complexes of silver, gold, copper, etc., are used for the electrodeposition of these metals.

### 5. Biological processes

Coordination compounds play many important roles in animals and plants. They are essential in storage and transport of oxygen, as electron transfer agents, as catalysts and in photosynthesis. Three important examples are given below:

(i) Haemoglobin: Haemoglobin is a protein which is present in blood. The main function of haemoglobin is to carry oxygen in the blood from the lungs to the tissues where it

delivers the oxygen molecules to myoglobin. The quadridentate macrocyclic ligand, the porphine molecule is an important

part of haemoglobin structure. The two H<sup>+</sup> ions bonded to nitrogen atoms are displaced and the metal ion coordinate simultaneously with all the four nitrogen atoms. The complex formed from porphine is called **porphyrin**. The Fe-complex is called heme. Haemoglobin molecule consists four heme groups embedded in a protein molecule. The iron in the heme group has the oxidation number +2. It is coordinated to the four nitrogen donor atoms in the porphine group and also, to a nitrogen donor atom in a ligand group which is attached to the protein. The sixth ligand is a water molecule, which binds to the Fe<sup>2+</sup> ion on the other side of the ring to complete the octahedral complex. Under these conditions, the haemoglobin molecule is called deoxyhaemoglobin and has a blue colour. The water ligand can be replaced readily by molecular oxygen to form red coloured oxyhaemoglobin. This haemoglobin flows from lungs to tissues where it is again deoxygenated.

The iron-heme complex is present in another class of proteins, called **cytochromes**. Cytochromes act as electron carriers which also play an essential part in metabolic processes.

Oxy-haemoglobin

In cytochromes iron undergoes rapid reversible redox reactions.

$$Fe^{3+} + e^{-} \rightleftharpoons Fe^{2+}$$

(ii) Chlorophyll: The chlorophyll molecule, which plays an essential role in photosynthesis also contains the porphyrin ring but the metal ion there is Mg<sup>2+</sup> rather than Fe<sup>2+</sup>. It is a green plant pigment and acts as a photosensitizer in the synthesis of carbohydrates in plants. It is structurally similar to heme.

$$6\text{CO}_2 + 6\text{H}_2\text{O} \xrightarrow{hv} \text{Chlorophyll} C_6\text{H}_{12}\text{O}_6 + 6\text{O}_2$$

$$CH_{2}$$
 $CH_{3}$ 
 $CH_{3}$ 
 $CH_{3}$ 
 $CH_{2}$ 
 $CH_{3}$ 
 $CH_{2}$ 
 $CH_{3}$ 
 $CH_{2}$ 
 $CH_{3}$ 
 $CH_{2}$ 
 $CH_{3}$ 
 $CH_{2}$ 
 $COOC_{20}$ 
 $COOC_{20}$ 
 $COOC_{20}$ 
 $COOC_{20}$ 

Structure of Chlorophyll

A molecule of chlorophyll can add one or two molecules of water axially. These coordinated water molecules through hydrogen bonding help the other chlorophyll molecules to associate with each other.

(iii) Vitamin  $B_{12}$ : It is a complex of cobalt with a quadridentate ligand which is similar to porphyrin ligand of haemoglobin. It has been observed that vitamin  $B_{12}$  is active only when cobalt is present in +1 oxidation state. It is a red crystalline substance which is slightly soluble in water. It is not found in plants but is found in all animal tissues. It is present mainly in milk, eggs, cheese and meat.

It is essential growth factor for many microorganisms.

### 6. Plant growth

Plants require a number of nutrients for healthy growth. Essential nutrients include a number of metals such as Fe, Zn, Cu, Mn, Mo, etc. For example, the deficiency of iron brings a disorder in plants known as **iron chlorosis**. This disorder affects the yield of fruit from citrus trees. Iron in +3 state present in the soil is mostly hydrolysed to form insoluble iron hydroxide Fe(OH)<sub>3</sub>, which cannot be taken up by plants. To overcome iron deficiency, the complex Fe(III)–EDTA is added to the soil. This complex is soluble in water and readily enters the roots of trees and reach to various parts of the plants where it is converted into useful compounds.

### 7. In medicinal field

- (i) The complex of calcium with EDTA is used for the treatment of lead poisoning. Lead readily replaces calcium in the complex and lead-EDTA complex is finally eliminated from the body in urine.
- (ii) The platinum complex cis [Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>] known as cis-platin is used as an antitumor agent in the treatment of cancer.

### 15.10 ORGANOMETALLIC COMPOUNDS

Compounds that contain at least one carbon-metal bond are called organometallic compounds. Zeise, in 1830, prepared the first organometallic compound by the action of ethylene on a solution of potassium chloroplatinate(II). In the last four decades, enormous work has been done in this field and many fascinating compounds have been synthesised and investigated. Grignard reagent, RMgX is a familiar example of organometallic compounds where R is an alkyl group. Diethyl zinc [Zn(C<sub>2</sub>H<sub>5</sub>)<sub>2</sub>], lead tetraethyl [Pb(C<sub>2</sub>H<sub>5</sub>)<sub>4</sub>], ferrocene [Fe(C<sub>5</sub>H<sub>5</sub>)<sub>2</sub>], dibenzene chromium [Cr(C<sub>6</sub>H<sub>6</sub>)<sub>2</sub>], metal carbonyls are other examples of organometallic compounds. The compounds of metalloids such as germanium and antimony and non-metallic elements such as boron and silicon are also included under this classification.

Organometallic compounds may be classified in three classes:

- 1. Sigma (σ) bonded complexes,
- 2. Pi  $(\pi)$  bonded complexes,
- 3. Complexes containing both  $\sigma$  and  $\pi$ -bonding characteristics.

## 1. Sigma bonded complexes

In these complexes, the metal atom and carbon atom of the ligand are joined together with a sigma bond, *i.e.*, the ligand contributes one electron and is, therefore, called one electron donor. Examples are:

- (i) Grignard reagent, R—Mg—X where R is an alkyl or aryl group and X is a halogen.
- (ii) Zinc compounds of the formula  $R_2$ Zn such as  $(C_2H_5)_2$ Zn. This was first isolated by Frankland in 1849. Other similar compounds are  $(CH_3)_4$ Sn,  $(C_2H_5)_4$ Pb,  $Al_2(CH_3)_6$ ,  $Al_2(C_2H_5)_6$  and  $Pb(CH_3)_4$ , etc.

Al<sub>2</sub>(CH<sub>3</sub>)<sub>6</sub> is a dimeric compound and has a structure similar to diborane, B<sub>2</sub>H<sub>6</sub>. It is an electron deficient compound and two methyl groups act as bridges between two aluminium atoms.

# **2.** $\pi$ -bonded organometallic compounds

These are the compounds of metals with alkenes, alkynes, benzene and other ring compounds. In these complexes, the metal and ligand form a bond that involves the  $\pi$  electrons of the ligand. Three common examples are Zeise's salt, ferrocene and dibenzene chromium. These are shown here:

Zeise's salts Fe  $K[PtCl_3(\eta^2-C_2H_4)]$  Fe $(\eta^5$ 

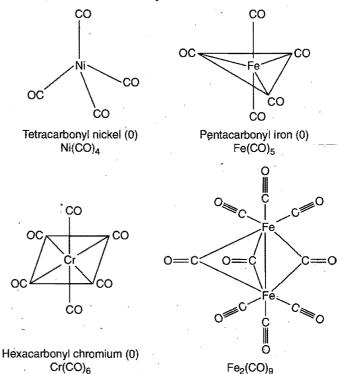

Ferrocene Dibenzene chromium  $Fe(\eta^5 - C_5H_5)_2$   $Cr(\eta^6 - C_6H_6)_2$ 

The number of carbon atoms bound to the metal in these compounds is indicated by the Greek letter ' $\eta$ ' (eta) with a number. The prefixes  $\eta^2$ ,  $\eta^5$  and  $\eta^6$  indicate that 2, 5 and 6 carbon atoms are bound to the metal in the compound.

# **3.** σ- and $\pi$ -bonded organometallic compounds

Metal carbonyls, compounds formed between metal and carbon monoxide belong to this class. These compounds possess both  $\sigma$ - and  $\pi$ - bonding. The oxidation state of metal atoms in these compounds is zero. Carbonyls may be monomeric, bridged or polynuclear. Carbonyls are mainly formed by the transition metals of VIth, VIIth and VIIIth groups.

Some well known examples are:

In a metal carbonyl, the metal-carbon bond possesses both the  $\sigma$ - and  $\pi$ -character. A  $\sigma$ -bond between metal and carbon atom is formed when a vacant hybrid bond of the metal atom overlaps with an orbital on C atom of carbon monoxide containing a lone pair of electrons.

$$\bigcirc M + + + \bigcirc C =: \longrightarrow \bigcirc M \bigcirc C = 0:$$

Formation of  $\pi$ -bond is caused when a filled orbital of the metal atom overlaps with a vacant antibonding  $\pi^*$  orbital of C atom of carbon monoxide. This overlap is also called back donation of electrons by metal atom to carbon. It has been shown below:

The  $\pi$ -overlap is perpendicular to the nodal plane of  $\sigma$ -bond.

In olefinic complexes, the bonding  $\pi$ -orbital electrons are donated to the empty orbital of the metal atom and at the same time back bonding occurs from filled orbital of the metal atom to the antibonding  $\pi$ -orbital of the olefin.

## Preparation of organometallic compounds

The following methods are generally employed for the preparation of organometallic compounds:

(i) Reaction between a metal and an organic halide: Alkali metal directly reacts with organic halide in ether to form organoalkali compounds.

$$2M + RX \xrightarrow{\text{Ether}} RM + MX$$

$$(M = \text{Li, Na, K})$$
 $C_4H_9\text{Br} + 2\text{Li} \longrightarrow C_4H_9\text{Li} + \text{LiBr}$ 
*n*-Butyl bromide

*n*-Butyl lithium

Grignard reagent is prepared when haloalkane in ether is allowed to stand over magnesium turnings for a few hours.

$$Mg + R - X \xrightarrow{Ether} R - Mg - X$$
Grignard reagent

(ii) By use of Grignard reagent: Tetraalkyl derivatives of silicon, germanium, tin and lead are prepared by the reaction of Grignard reagent and the metal halide. The reaction is carried in ether.

$$4\text{CH}_3\text{MgBr} + \text{PbCl}_4 \xrightarrow{\text{Ether}} (\text{CH}_3)_4\text{Pb} + 4\text{Mg(Br)Cl}$$
  
 $2\text{CH}_3\text{MgBr} + \text{CdCl}_2 \xrightarrow{\text{Ether}} (\text{CH}_3)_2\text{Cd} + 2\text{Mg(Br)Cl}$   
Similarly, organolithium compounds may be used.

$$SnCl_4 + 4C_4H_9Li \longrightarrow (C_4H_9)_4Sn + 4LiCl$$
*n*-Butyl tin

(iii)  $\pi$ -complexes such as ferrocene, Zeise's salt and dibenzene chromium are prepared by the application of following reactions:

(iv) Metal carbonyls are formed by direct carbonylation of the metal or reductive carbonylation.

Ni + 4CO 
$$\xrightarrow{80^{\circ}\text{C}}$$
 Ni(CO)<sub>4</sub>

$$OsO_4 + 9CO \xrightarrow{\text{High press.}} Os(CO)_5 + 4CO_2$$

Bridged carbonyls can be obtained by photolysis of monomeric carbonyls.

$$2Fe(CO)_5 \longrightarrow Fe_2(CO)_9 + CO$$

## Applications of organometallic compounds

The applications of organometallic compounds are numerous. Some important ones are mentioned here:

- 1. Tetraethyl Lead (TEL) is used as antiknock compound in gasoline.
  - 2. Silicones are used as polymers of unique properties.
- 3. Organoalkali and Grignard reagents are used in many organic synthetic reactions.
- 4. The extraction and purification of nickel is based on the formation of organometallic compound, Ni(CO)<sub>4</sub>.
- 5. Organometallic compounds are used as homogeneous and heterogeneous catalysts. Wilkinson's catalyst,  $[Rh(P \cdot Ph_3)_3Cl]$  is used as homogeneous catalyst in the hydrogenation of alkenes. Zeigler-Natta catalyst  $[TiCl_4]$  and triethyl aluminium] acts as a heterogeneous catalyst in the polymerisation of ethylene into polyethylene.

# **SOME SOLVED PROB**

**Example 1.** What is the coordination number of the central metal ions in the following complexes?

- (i)  $[Cu(NH_3)_4]^{2+}$
- (ii)  $[Fe(C_2O_4)_3]^{3-}$
- (iii)  $[Pt(en)_2Cl_2]$
- (iv)  $[Mo(CN)_8]^{4-}$
- (v)  $[Fe(EDTA)]^-$
- (vi)  $[Pd(H_2O)_2(ONO)_2I_2]$

### Solution:

(i) NH<sub>3</sub> is monodentate ligand.

Points of attachment with  $Cu^{2+} = 4 \times 1 = 4$ C.N. of  $Cu^{2+} = 4$ 

(ii)  $C_2O_4^{2-}$  is a bidentate ligand. Points of attachment with  $Fe^{3+} = 3 \times 2 = 6$ 

 $- C.N. \text{ of } Fe^{3+} = 6$ 

(iii) 'en' is a bidentate ligand and Cl is a monodentate ligand.

Points of attachment with  $Pt^{2+} = 2 \times 2 + 2 \times 1 = 6$ C.N. of  $Pt^{2+} = 6$ 

(iv) CN is a monodentate ligand.

Points of attachment with  $Mo^{4+} = 8 \times 1 = 8$ 

C.N. of  $Mo^{4+} = 8$ 

(v) EDTA is a hexadentate ligand.

Points of attachment with  $Fe^{3+} = 6 \times 1 = 6$ 

C.N. of  $Fe^{3+} = 6$ 

(vi) Points of attachment with

$$Pd^{4+} = 2 \times 1 + 2 \times 1 + 2 \times 1 = 6$$
  
C.N. of  $Pd^{4+} = 6$ 

Example 2. Calculate the oxidation state of the central metal atom in the following:

- (i)  $[Co(NH_3)_5Cl]^{2+}$
- (ii)  $K_4[Fe(CN)_6]$
- (iii)  $[Co(NO_2)_2(py)_2(NH_3)_2]NO_3$  (iv)  $Ni(CO)_4$
- $(v) [Fe(EDTA)]^T$

### Solution:

(i) 
$$x + 5 \times (0) - 1 = +2$$
  
 $x = +2 + 1 = 3$  Oxi. state of Co = +3

 $4 \times (+1) + x + 6 \times (-1) = 0$ (ii)

or x = +6 - 4 = +2Oxi. state of Fe = +2

 $x + 2 \times (-1) + 2 \times (0) + 2 \times (0) -1 = 0$ (iii)

or x = +2 +1 = +3Oxi. state of Co = +3

 $x + 4 \times (0) = 0$ (iv)

x = 0Oxi. state of Ni = 0

 $x + 1 \times (-4) = -1$ or x = +4 - 1 = +3Oxi. state of Fe =+3

Example 3. Give the IUPAC names of the following compounds:

- (i)  $K_3[Al(C_2O_4)_3]$
- (ii)  $[Pt(NH_3)_4(NO_2)Cl]SO_4$
- (iii)  $K_3[Cr(CN)_6]$
- (iv)  $[Co(NH_3)_5ONO]Cl_2$

 $(v) [Cr(NH_3)_5CO_3]Cl$ 

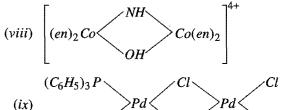

[L.I.T. 1996]

(vi)  $[Cr(NH_3)_5(NCS)][ZnCl_4]$ 

[L.I.T. 1997]

 $P(C_6H_5)_3$ 

(vii)  $KAu(CN)_2$ 

### Solution:

- (i) Potassium trioxalatoaluminate (III)
- (ii) Tetraamminechloronitrito-n-platinum (IV) sulphate
- (iii) Potassium hexacyanochromate (III)
- (iv) Pentaamminenitritito-o-cobalt (III) chloride
- (v) Pentaamminecarbonatochromium (III) chloride
- (vi) Pentaammineisothiocyanatochromium (III) tetrachlorozincate (II)
- (vii) Potassium dicyanoaurate (I)
- (viii) Bis (ethylenediamine) cobalt (III)-μ-imido-μ-hydrobis (ethylenediammine) cobalt (III) ion
- (ix) Chlorotriphenylphosphinepalladium (II)-μ-dichlorochlorotriphenylphosphinepalladium (II).

**Example 4.** Name the type of isomerism exhibited by the following isomers:

- (i)  $[Cr(NH_3)_6][Cr(CN)_6]$  and  $[Cr(NH_3)_4(CN)_2][Cr(NH_3)_2(CN)_4]$
- (ii)  $[Co(py)_2(H_2O)_2Cl_2]Cl$  and  $[Co(py)_2(H_2O)Cl_3]H_2O$
- $(iii) [Pt(NH_3)_4Br_2]Cl_2$ and  $[Pt(NH_3)_4Cl_2]Br_2$
- (iv)  $[Co(NH_3)_5NO_2]Cl_2$  and  $[Co(NH_3)_5ONO]Cl_2$

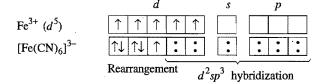

Solution: (i) Coordination isomerism

- (ii) Hydrate isomerism
- (iii) Ionisation isomerism
- (iv) Linkage isomerism

Example 5. How would you account for the following? (a)  $[Fe(CN)_6]^{3-}$  is weakly paramagnetic while  $[Fe(CN)_6]^4$ is diamagnetic.

- (b) Ni(CO)<sub>4</sub> possesses tetrahedral geometry while  $[Ni(CN)_4]^{2-}$  is square planar.
- (c)  $[Ni(CN)_4]^{2-}$  is diamagnetic while  $[NiCl_4]^{2-}$  is paramagnetic.

**Solution**: (a)  $[Fe(CN)_6]^{3-}$  involves  $d^2sp^3$  hybridization.

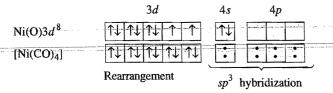

One d-orbital is singly occupied, hence it is weakly paramagnetic in nature.

 $[Fe(\tilde{CN})_6]^{4-}$  involves also  $d^2sp^3$  hybridization but it has Fe<sup>2+</sup> ion as central ion.

All orbitals are doubly occupied, hence it is diamagnetic in nature.

(b) In the formation of Ni(CO)<sub>4</sub>, nickel undergoes sp<sup>3</sup> hybridization, hence it is tetrahedral in shape.

In the formation of [Ni(CN)<sub>4</sub>]<sup>2-</sup>, Ni<sup>2+</sup> ion undergoes dsp<sup>2</sup> hybridization, hence it is square planar in shape.

(c) In [Ni(CN)<sub>4</sub>]<sup>2-</sup> all orbitals are doubly occupied, hence it is diamagnetic while in [NiCl<sub>4</sub>]<sup>2-</sup>, two orbitals are singly occupied, hence it is paramagnetic in nature.

$$[NiCl_4]^{2-}$$

$$1 \downarrow \uparrow \downarrow \uparrow \downarrow \uparrow \uparrow \uparrow$$

$$sp^3 \text{ hybridization}$$

Strong field ligands like CN, CO, en, NO<sub>2</sub> have very strong electron donating tendency, hence, electrons of central metal ion pair up against Hund's rule (low spin complex).

Example 6. A metal complex having composition  $Cr(NH_3)_4Cl_2Br$  has been isolated in two forms (A) and (B). The form (A) reacts with AgNO<sub>3</sub> to give a white precipitate readily soluble in dilute aqueous ammonia, whereas (B) gives a pale yellow precipitate soluble in concentrated ammonia. Write the formula of (A) and (B) and state the hybridization of chromium in each. Calculate the magnetic moments (spinonly value). [I.I.T. 2001]

### **Solution:**

Complex, Cr(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>Br, has two isomers. Since, coordination number of Cr is six, the two forms may be represented in the following way:

$$\begin{array}{cccc} [\text{Cr}(\text{NH}_3)_4\text{ClBr}] & \text{Cl} & [\text{Cr}(\text{NH}_3)_4\text{Cl}_2] & \text{Br} \\ & & (\textit{B}) & & & & & & & & & & & \\ \end{array}$$

[Cr(NH<sub>3</sub>)<sub>4</sub>ClBr] Cl + AgNO<sub>3</sub> 
$$\longrightarrow$$
 [Cr(NH<sub>3</sub>)<sub>4</sub>ClBr] NO<sub>3</sub> +

(A) AgCl $\downarrow$ 

White ppt.

AgCl + 2NH<sub>4</sub>OH  $\longrightarrow$  Ag(NH<sub>3</sub>)<sub>2</sub>Cl + 2H<sub>2</sub>O

Soluble

[Cr(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>] Br + AgNO<sub>3</sub>  $\longrightarrow$  [Cr(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>] NO<sub>3</sub>+ AgBr $\downarrow$ 

(B) Pale yellow

(B) Pale 
$$AgBr + 2NH_4OH \longrightarrow Ag(NH_3)_2Br + 2H_2O$$
 Soluble Soluble

The state of hybridization of chromium in both the complexes is  $d^2sp^3$ . Chromium is in trivalent state (Cr<sup>3+</sup>).

As three unpaired electrons are present,

the magnetic moment 
$$=\sqrt{n(n+2)}$$
 B.M.

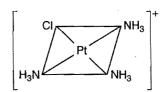

$$= \sqrt{3 \times 5}$$
 B.M. = 3.87 B.M.

Example 7. Platinum (II) forms square planar complexes and platinum (IV) gives octahedral complexes. How many geometrical isomers are possible for each of the following complexes? Describe their structures:

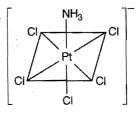

- (a)  $[Pt(NH_3)_3Cl]^+$
- (c)  $[Pt(NH_3)_2ClNO_2]$
- (b)  $[Pt(NH_3)Cl_5]^-$ (d)  $[Pt(NH_3)_4ClBr]^{2+}$

### Solution:

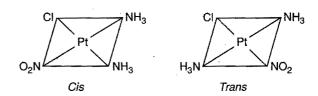

(a) No isomers are possible for a square planar complex of the type  $MA_3B$ .

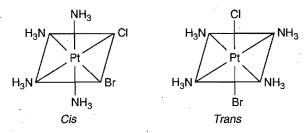

(b) No isomers are possible for an octahedral complex of the type  $MAB_5$ .

(c) Cis and trans-isomers are possible for a square planar complex of the type  $MA_2BC$ .

(d) Cis and trans-isomers are possible for an octahedral complex of the type  $MA_4BC$ .

### **Example 8.** Answer the following:

- (a) Why ligand field theory is also called crystal field theory?
  - (b) What is crystal field splitting?
  - (c) What are  $t_{2g}$  and  $e_g$  orbitals?

### **Solution:**

- (a) According to this theory, the bond between metal ion and ligands is ionic, *i.e.*, the electrostatic interactions are similar to those present in the crystals amongst the ions. That is why, the ligand field theory is also called crystal field theory.
- (b) In the free transition metal atom or ion, all the five d-orbitals are degenerate but under the influence of ligands when complex formation occurs, the d-orbitals are split into two sets of orbitals  $t_{2g}$  and  $e_g$  orbitals. This is called crystal field splitting.
- (c) Under the influence of ligands, when complex formation occurs, the five degenerate d-orbitals are split into two types of d-orbitals  $t_{2g}$  (three degenerate orbitals,  $d_{xy}$ ,  $d_{yz}$  and  $d_{zx}$ ) and  $e_g$  (two degenerate orbitals,  $d_{z^2}$  and  $d_{x^2-y^2}$ ). Both sets have different energies.

In octahedral complexes,  $t_{2g}$  orbitals possess low energy in comparison to  $e_g$  orbitals while in tetrahedral complexes,  $t_{2g}$  orbitals possess high energy in comparison to  $e_g$  orbitals.

**Example 9.** Arrange the following complexes in order of increasing crystal field splitting:

$$[Fe(H_2O)_6]^{2+}$$
,  $[Fe(H_2O)_6]^{3+}$ ,  $[FeCl_6]^{4-}$  and  $[Ru(H_2O)_6]^{3+}$ 

### Solution :

The strength of the splitting depends on the ligand, the charge on the metal and the position of the metal in the periodic table

Ligand  $Cl^-$  is lower in the spectrochemical series than  $H_2O$ . Thus,  $[FeCl_6]^{4-}$  has low splitting relative to others.

In  $[FeCl_6]^{4-}$  and  $[Fe(H_2O)_6]^{2+}$  complexes, iron is in its +2 oxidation state but the metal is in +3 oxidation state in  $[Fe(H_2O)_6]^{3+}$  and  $[Ru(H_2O)_6]^{3+}$  complexes. The complexes with +3 oxidation states have larger splitting.

$${\rm [FeCl_6]}^{4-} \, < \, {\rm [Fe(H_2O)_6]}^{2+} \, < \, {\rm [Fe(H_2O)_6]}^{3+}, \ \, {\rm [Ru(H_2O)_6]}^{3+}$$

Three complexes contain iron, a metal with 3d valence electrons but the fourth contains ruthenium with 4d valence

electrons. The metal with 4d electrons has larger splitting in comparison to the metal with 3d electrons. Thus, the order of crystal field splitting in the given complexes is:

$$[FeCl_6]^{4-} < [Fe(H_2O)_6]^{2+} < [Fe(H_2O)_6]^{3+} < [Ru(H_2O)_6]^{3+}$$

**Example 10.** For each octahedral complex ion,  $[Fe(H_2O)_6]^{2+}$  and  $[Fe(CN)_6]^{4-}$ , draw an orbital splitting diagram and predict the number of unpaired electrons and the magnetic nature.

**Solution:** Fe<sup>2+</sup> has  $3d^6$  configuration. H<sub>2</sub>O is a weakfield ligand so it forms high spin complex while CN<sup>-</sup> is a strong-field ligand and forms low spin complex. The orbital splitting diagrams are shown below:

The  $[Fe(H_2O)_6]^{2+}$  has four unpaired electrons and hence, it is paramagnetic in nature. The  $[Fe(CN)_6]^{4-}$  has no unpaired electron and hence, it is diamagnetic in nature.

**Example 11.** Explain when hexacyano complexes of metals in their +2 oxidation state are usually yellow, but the corresponding hexacqua compounds are often blue or green.

### **Solution:**

The ligand,  $CN^-$  is near the top of the spectrochemical series, it generates a relatively large energy gap between the two sets of d-orbitals. The hexacyano complexes are yellow because they absorb high-energy indigo light. The corresponding aqua complexes have a much smaller crystal field splitting energy. They absorb orange or red light, thus appearing blue or green.

**Example 12.** Indicate the types of isomerism exhibited by the following complexes and draw the structures of these isomers.

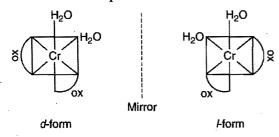

- (a)  $K[Cr(H_2O)_2(C_2O_4)_2]$
- (b)  $[Co(en)_3]Cl_3$
- (c)  $[Co(NH_3)_5NO_2](NO_3)_2$
- (d)  $[Pt(NH_3)(H_2O)Cl_2]$

### **Solution:**

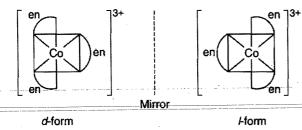

(a)  $K[Cr(H_2O)_2(C_2O_4)_2]$  shows geometrical isomerism.

$$K^{+}$$
 $\begin{bmatrix} H_{2}O \\ K^{+} \end{bmatrix}$ 
 $Cis$ -isomer
 $K^{+}$ 
 $\begin{bmatrix} H_{2}O \\ K^{+} \end{bmatrix}$ 
 $K^{+}$ 
 $\begin{bmatrix} H_{2}O \\ K^{+} \end{bmatrix}$ 
 $K^{+}$ 
 $\begin{bmatrix} H_{2}O \\ K^{+} \end{bmatrix}$ 
 $\begin{bmatrix} H_{2}O \\ K^{+} \end{bmatrix}$ 

Cis-isomer exhibits optical isomerism.

(b) [Co(en)<sub>3</sub>]Cl<sub>3</sub> exhibits optical isomerism.

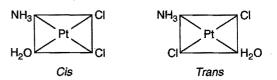

(c)  $[Co(NH_3)_5NO_2](NO_3)_2$  shows ionisation isomerism.  $[Co(NH_3)_5NO_2](NO_3)_2$ ,  $[Co(NH_3)_5NO_3](NO_2)(NO_3)$ 

This also shows linkage isomerism.

[Co(NH<sub>3</sub>)<sub>5</sub>NO<sub>2</sub>](NO<sub>3</sub>)<sub>2</sub>,

[Co(NH<sub>3</sub>)<sub>5</sub>(ONO)]NO<sub>3</sub>

(d) [Pt(NH<sub>3</sub>)(H<sub>2</sub>O)Cl<sub>2</sub>] shows geometrical isomerism.

**Example 13.** Write down the IUPAC name for each of the following complexes and indicate the oxidation state, electronic configuration and coordination number of the central atom in the complex. Also give stereochemistry and magnetic moment of the complex.

- (i)  $K[Cr(H_2O)_2(C_2O_4)_2] \cdot 3H_2O$
- (ii) [ $Co(NH_3)_5Cl$ ] $Cl_2$
- (iii)  $CrCl_3(py)_3$
- (iv)  $Cs[FeCl_4]$
- $(v) K_4[Mn(CN)_6]$

### **Solution:**

Complex	TUPAC name	Oxidation state	Electronic configuration	Coordination number	Stereo- chemistry	Magnetic moment
(i) K[Cr(H <sub>2</sub> O) <sub>2</sub> (C <sub>2</sub> O <sub>4</sub> ) <sub>2</sub> ]·3H <sub>2</sub> O	Potassium diaquodioxalatochromate (III) hydrate	+3	3d <sup>3</sup>	6	Octahedral $d^2sp^3$ -hybridization	$\sqrt{3\times5}$ = 3.87 B.M.
(ii) [Co(NH <sub>3</sub> ) <sub>5</sub> Cl]Cl <sub>2</sub>	Pentaamminechloridocobalt (III) chloride	+3	3d <sup>6</sup>	6	Octahedral	0
(iii) CrCl <sub>3</sub> (py) <sub>3</sub>	Trichloridotripyridinechromium (III)	+3	$3d^3$	. 6	Octahedral	$\sqrt{3 \times 5}$ = 3.87 B.M.
(iv) Cs[FeCl <sub>4</sub> ]	Caesium tetrachloridoferrate (III)	+3	3d <sup>5</sup>	4	Tetrahedral	$\sqrt{5 \times 7}$ = 5.92 B.M.
(v) K <sub>4</sub> [Mn(CN) <sub>6</sub> ]	Potassium hexacyanomanganate (II)	+2	3d <sup>5</sup>	6	Octahedral	$\sqrt{1\times3}$ = 1.73 B.M.

**Example 14.** What is meant by chelate effect? Give an example.

### **Solution:**

When a bidentate or polydentate ligand contains donor atoms in such a way that after coordinating with central metal atom forms a five or six membered ring, the effect is called 'chelate effect'.

$$\begin{bmatrix} H_2C-H_2N & NH_2-CH_2 \\ | & | & NH_2-CH_2 \end{bmatrix}^{2+}$$

$$Diethylenediamminecupric (II) ion$$

**Example 15.** What will be the correct order for the wavelengths of absorption in the visible region of the following?

 $[Ni(H_2O)_6]^{2+}, [Ni(NH_3)_6]^{2+}, [Ni(NO_2)_6]^{4-}$ 

#### Solution

In all the three complexes, the central metal ion is the same, hence, the increasing field strengths of the ligands from the spectrochemical series are in the order:

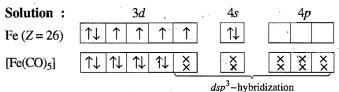

$$H_2O < NH_3 < NO_2$$

Thus, the energies absorbed for excitation will be in the order:

$$[Ni(H_2O)_6]^{2+} < [Ni(NH_3)_6]^{2+} < [Ni(NO_2)_6]^{4-}$$

As  $E = \frac{hc}{\lambda}$ , the wavelength absorbed will be in opposite order.

**Example 16.** Using valence bond theory explain the geometry and magnetic behaviour of pentacarbonyliron (III).

Hence, Fe(CO)<sub>5</sub> has trigonal bipyramidal geometry and as no unpaired electron is present, it is diamagnetic.

**Example 17.**  $[NiCl_4]^{2-}$  is paramagnetic while  $Ni(CO)_4$  is diamagnetic though both are tetrahedral. Why?

### Solution:

In Ni(CO)<sub>4</sub>, the oxidation state of nickel is zero and CO is a strong ligand. Due to strong ligand field, the unpaired electrons of 3*d*-orbitals get paired by 4*s*-electrons.

In [NiCl<sub>4</sub>]<sup>2-</sup>, the oxidation state of nickel is +2 and Cl<sup>-</sup> is a weak ligand. Due to weak ligand field, there is no regrouping of electrons.

**Example 18.** Draw crystal field energy level diagrams and predict the number of unpaired electrons for the following complexes:

- (a)  $[FeCl_4]^-$  (tetrahedral)
- (b)  $[NiCl_4]^{2-}$  (tetrahedral)
- (c)  $[Cr(en)_3]^{3+}$  (octahedral)

### **Solution:**

(a)	(b)	(c)
Cl is weak field	Cl is a weak field	(en) is a strong field
ligand. Thus, the	ligand. Thus, the	ligand. The electrons
complex is high spin.	complex is high spin.	occupy the orbitals
All the five orbitals	$Ni^{2+}(3d^8)$	of lower energy.
are singly occupied.		$\operatorname{Cr}^{3+}(3d^3)$
$\uparrow$ $\uparrow$ $\uparrow$	$\uparrow \downarrow \uparrow \uparrow$	
<u> </u>	1 1	$\begin{array}{ c c c c c c c c c c c c c c c c c c c$
No. of unpaired		
electrons $= 5$	electrons = 2	electrons = 3

**Example 19.** Explain why nearly all tetrahedral complexes are high spin?

### Solution:

Because none of the orbitals point directly at the ligands in tetrahedral geometry and there are only four ligands instead of six (as in octahedral geometry), the crystal field splitting in tetrahedral complexes is only about half of that in octahedral complexes. Consequently,  $\Delta$  is almost always smaller than spin-pairing energy P, and nearly all tetrahedral complexes are high spin.

**Example 20.** Why are metals complexed in biological systems?

### **Solution:**

There are two main reasons. These are:

- (i) Uncomplexed metal ions, e.g., Fe(III) may not dissolve in water at physiological pH.
- (ii) Uncomplexed metal ions may not have the required oxidation state. For example, in vitamin  $B_{12}$ , cobalt has +1 oxidation state which is not stable when uncomplexed.

**Example 21.** Name two coordination compounds which are biologically important.

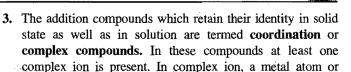

### **Solution:**

dination.

- (i) Haemoglobin—an iron complex—the red pigment in the blood that transports oxygen.
- (ii) Chlorophyll—a magnesium complex—a green pigment in plants acts as a catalyst (photosensitizer) in the synthesis of carbohydrates.

# Ö

# SUMMARY AND IMPORTANT POINTS TO REMEMBER

ion is surrounded by a number of groups through coor-

compounds, and (ii) Coordination or complex compounds.

2. The addition compounds which are stable in solid state but are broken down into individual constituents when dissolved in water are called **double salts.** Mohr's salt, potash alum,

carnallite, etc., are some examples of double salts.

1. When solutions of two or more simple stable compounds in

molecular proportions are allowed to evaporate, crystals of

new compounds may be formed. These compounds are

termed molecular or addition compounds. Addition com-

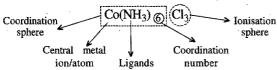

pounds are of two types: (i) Double salts or lattice

4. Complex compounds are mainly formed by transition metals but to a small extent by other metals such as magnesium in chlorophyll. Transition metals form complexes due to the given reasons:

- (i) Small size, (ii) high nuclear charge, (iii) a number of vacant orbitals of equivalent energy where the electrons donated by ligands are accommodated.
- 5. The neutral molecules, anions or cations which are directly linked with the central metal atom or ion in a complex ion are called **ligands**. The ligand at least consists one donor atom having a lone pair of electrons which it can donate to metal atom or ion. Ligands can be classified on the basis of number of donor atoms. They are termed monodentate, bidentate, tridentate, etc. The ligands having two or more donor groups are called polydentate. Polydentate ligand is known as **chelating ligand** if on coordination it results in the formation of a closed or cyclic ring structure. The complexes, thus, formed are called **chelates**.
- 6. The number of atoms of the ligands that are directly bound to the central metal atom or ion by coordinate bonds is known as coordination number of the metal atom or ion. It is actually the number of chemical bonds which the ligands form with central metal atom or ion. The most common coordination number are 4 or 6. The central metal atom or ion and the ligands that are directly attached to it are enclosed in a square bracket. This is called coordination sphere. It behaves as a single unit. The ions present outside the coordination sphere form ionisation sphere.

$$K_4Fe(CN)_6 \iff 4K^+ + [Fe(CN)_6]^{4-}$$
  
 $[Cu(NH_3)_4]SO_4 \iff [Cu(NH_3)_4]^{2+} + SO_4^{2-}$ 

Charge on the complex ion = oxidation number of metal ion + charge on the ligands

- 7. Effective atomic number (EAN) is defined as the resultant number of electrons with the metal atom or ion after gaining electrons from donor atoms after ligands.
  - EAN = atomic number of the metal number of electrons lost in ion formation + number of electrons gained from the donor atoms of the ligands.
- **8.** The following points are followed in naming complex compounds:
  - (i) Cation is named first followed by anion.
  - (ii) In the coordination sphere, the ligands are named alphabetically. Anionic ligands ending with -ide are named by replacing -ide by suffix -o or by replacing -e by -o. Ligands whose names end in -ite or -ate become -ito or -ato, i.e., by replacing the ending -e with -o. Neutral ligands are given the same names as the neutral molecules. However, H<sub>2</sub>O is named aqua and NH<sub>3</sub> ammine. Positively charged ligands have suffix -ium. If the number of a particular ligand is more than one, the number is indicated by using di, tri, tetra, penta, etc. However, when the name of the ligand includes a number, then bis, tris, etc., are used.

- (iii) The oxidation state of the central metal is shown by Roman numeral in bracket immediately following its name.
- (iv) Complex positive ions and neutral coordination compounds have no special ending but complex negative ions always end in the suffix -ate.
- Coordination compounds exhibit structural isomerism as well
  as stereoisomerism. Structural isomerism is displayed when
  different ligands are present within coordination spheres.
  The coordination compounds exhibit various types of
  structural isomerism.
  - (i) Ionisation isomerism: Isomers give different ions in solution.

Examples: [Co(NH<sub>3</sub>)<sub>5</sub>Br]Cl; [Co(NH<sub>3</sub>)<sub>5</sub>Cl]Br.

- (ii) Hydrate isomerism: Isomers having  $H_2O$  as a ligand or as water of hydration.
  - **Examples:**  $[Cr(H_2O)_6]Cl_3;$   $[CrCl(H_2O)_5]Cl_2\cdot H_2O;$   $[CrCl_2(H_2O)_4]Cl\cdot 2H_2O.$
- (iii) Coordination isomerism: The ligands are interchanged in both the cationic and anionic ions.

  Examples: [Co(NH<sub>2</sub>)][Cr(NN<sub>2</sub>] [Cr(NH<sub>2</sub>)]

**Examples:**  $[Co(NH_3)_6][Cr(CN)_6];$   $[Cr(NH_3)_6]$   $[Co(CN)_6].$ 

- (iv) Linkage isomerism: This type of isomerism exists when ambidentate ligand is present.
- Examples: [Co(NH<sub>3</sub>)<sub>5</sub>ONO]Cl<sub>2</sub>; [Co(NH<sub>3</sub>)<sub>5</sub>NO<sub>2</sub>] Cl<sub>2</sub>.

  10. Stereoisomerism: It arises on account of the different positions and arrangement of ligands in space around the metal ion. It is of two types: (a) geometrical and (b) optical. Geometrical isomerism is common in coordination number 4 (square planar) and coordination number 6 compounds. This type of isomerism is termed *cis-trans* isomerism. When the ligands occupy adjacent positions, the isomer is called *cis*form and when opposite positions, the isomer is termed *trans* isomer. The square planar complexes having general formulae *Ma*<sub>2</sub>*b*<sub>2</sub>, *Ma*<sub>2</sub>*bc* or *Mabcd* show *cis-trans* isomerism. Square planar complexes having unsymmetrical bidentate ligands can also show geometrical isomerism.

Geometrical isomerism is not observed in complexes of coordination numbers 2 and 3. Square planar complexes of the type  $Ma_4$ ,  $Ma_3b$  and  $Mab_3$  do not show geometrical isomerism. Geometrical isomerism is also not observed in tetrahedral complexes.

Octahedral complexes of the type  $Ma_4b_2$ ,  $Ma_2b_4$ ,  $Ma_4bc$  and  $Ma_3b_3$  exhibit geometrical isomerism.

11. A coordination compound which can rotate the plane of polarised light is said to be optically active. The optical isomers are pair of molecules which are non-superimposable mirror image of each other. The isomer which rotates the plane of polarised light to right direction is termed dextro while the isomer which rotates the plane of polarised light to left direction is termed laevo form. Optical isomerism is very common in octahedral complexes. Octahedral compounds of general formulae  $[Ma_2b_2c_2]^{n\pm}$ ,  $[M(AA)_3]^{n\pm}$ ,  $[M(AA)_2a_2]^{n\pm}$ ,  $[M(AA)_2ab]^{n\pm}$  and  $[M(AB)_3]^{n\pm}$  where AA = symmetrical bidentate ligands and AB = unsymmetrical bidentate ligands.

- 12. Werner, in 1893, proposed the coordination theory to explain the properties and structures of various metal ammines. The important postulates of the theory are:
  - (a) Every element exhibits two types of valency: (i) Primary valency and (ii) Secondary valency. Primary valency corresponds to oxidation state of metal and secondary valency represents the coordination number of the metal. Primary valency is satisfied by negative ions and is ionisable. The secondary valency is satisfied by neutral molecules or negative ions or both. This valency is nonionic. Metal and neutral molecules or negative ions which satisfy secondary valency are enclosed in square bracket and termed as coordination sphere.
  - (b) Every element tends to satisfy both its valencies. A negative ion when present in coordination sphere shows a dual behaviour. It satisfies both primary and secondary valencies. The presence of negative ion in the coordination sphere reduces the charge on the complex ion by the amount of charge possessed by it and the negative ions present in the coordination sphere are not ionised.
  - (c) The ligands in coordination sphere are directed towards fixed positions in space. The geometry of the complex ion depends on coordination number. If the coordination number is 6, the complex is octahedral. On the other hand, if the coordination number is 4, the geometry of the complex may be tetrahedral or square planar.
- 13. Valence bond theory describes the bonding in complexes in terms of two-electron, coordinate-covalent bonds resulting from overlap of filled ligand orbitals with vacant metal hybrid orbitals that point in the direction of the ligands: sp (linear);  $sp^3$  (tetrahedral);  $dsp^2$  (square planar) and  $d^2sp^3$

This theory explains with reasonable success the formation, magnetic behaviour and geometrical shapes of coordination compounds. It, however, fails to provide a quantitative interpretation of magnetic behaviour and explanation about optical properties of coordination compounds.

### **Examples:**

### (a) Octahedral complexes:

and  $sp^3d^2$  (octahedral).

(i) Inner orbital (low spin) complexes involving  $d^2sp^3$  hybridization:

 $[Fe(CN)_6]^{3-}$ ,  $[Co(CN)_6]^{3-}$ ,  $[Cr(NH_3)_6]^{3+}$ ,  $[Co(NH_3)_6]^{3+}$ , etc.

(ii) Outer orbital (high spin) complexes involving  $sp^3d^2$  hybridization:

 $[\text{CoF}_6]^{3-}$ ,  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$ ,  $[\text{MnF}_6]^{3-}$ ,  $[\text{Ni}(\text{NH}_3)_6]^{2+}$ , etc.

- (b) Tetrahedral complexes involving  $sp^3$  hybridization:  $[NiCl_4]^{2-}$ ,  $[Cu(Cl_4)]^{2-}$ ,  $Ni(CO)_4$ ,  $[Zn(NH_3)_4]^{2+}$ , etc.
- (c) Square planar complexes involving  $dsp^2$  hybridization:  $[Ni(CN)_4]^{2-}$ ,  $[Cu(NH_3)_4]^{2+}$ , etc.
- 14. Crystal field theory assumes that the metal-ligand bonding is entirely ionic. Because of electrostatic repulsions between the d electrons and the ligands, the d-orbitals are raised in energy and are differentiated by an energy separation called

the crystal field splitting,  $\Delta$ . In octahedral complexes the  $d_z^2$ ,  $d_{x^2-y^2}$  orbitals (e.g., set of orbitals) have higher energy than  $d_{xy}$ ,  $d_{yz}$  and  $d_{zx}$  orbitals (e.g., set of orbitals). Tetrahedral complexes exhibit just opposite splitting pattern.

The colours of complexes are due to electronic transitions from one set of d-orbitals to another and the transition energies depend on the position of ligand in the spectrochemical series. Weak field ligands give small  $\Delta$  values and strong field ligands give large  $\Delta$  values. Crystal field theory accounts for magnetic properties of complexes in terms of the relative values of  $\Delta$  and the spin pairing energy. Small  $\Delta$  values favour high spin complexes (maximum number of unpaired d electrons) and large  $\Delta$  values favour low spin complexes.

15. In general, higher the charge density on the central ion, the greater is the stability of its complexes. Electronegativity of the central ion also influences the stability. The higher the oxidation state of the metal, the more stable is the complex. The more basic ligand forms the complex with greater stability. The cyano and ammine complexes are far more stable than those formed by halide ions.

Chalating ligands form more stable complexes as compared.

Chelating ligands form more stable complexes as compared to monodentate ligands.

- **16.** Coordination compounds are generally prepared by the application of :
  - (a) Ligand substitution reactions:  $[Cu(H<sub>2</sub>O)<sub>4</sub>]<sup>2+</sup> + 4NH<sub>3</sub> \longrightarrow [Cu(NH<sub>3</sub>)<sub>4</sub>]<sup>2+</sup> + 4H<sub>2</sub>O$
  - (b) Direct mixing of reagent:  $PtCl_2 + 2H_2N - CH_2 - CH_2 - NH_2 - Pt(en)_2Cl_2$
  - (c) Redox reaction:  $K_2Cr_2O_7 + 7H_2C_2O_4 + 2K_2C_2O_4 \longrightarrow 2K_3[Cr(C_2O_4)_3]$  $+6CO_2 + 7H_3C_2O_4 + 2K_2C_2O_4 \longrightarrow 2K_3[Cr(C_2O_4)_3]$
- 17. The complexes find applications in various fields:
  - (a) Analytical chemistry—Cu<sup>2+</sup>, Fe<sup>3+</sup>, Ni<sup>2+</sup>, etc., are tested in the form of complexes. Ca<sup>2+</sup>, Mg<sup>2+</sup> and Zn<sup>2+</sup> ions are estimated volumetrically by EDTA. Many ions are quantitatively estimated by using a number of organic ligands.
  - (b) Coordination complexes of transition metals exhibit a variety of colours. This forms the basis of colorimetric estimations.
  - (c) Complexes act as oxidation-reduction indicators and sequestering reagents. Hardness of water is estimated by use of EDTA.
  - (d) Silver and gold are extracted by the use of complex formation.
  - (e) Fixing of negative is done in photography by use of hypo solution. It forms soluble complex with silver bromide.
  - (f) During electroplating, complexes are used in electrolytic bath.
  - (g) Cis-platin, [Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>], is used in the treatment of cancer.

British anti-lewisite (BAL) is used as antidote for treating poisoning by As, Hg, Au, Bi, Pb and Cd.

(h) Haemoglobin is a complex of Fe, chlorophyll is a complex of Mg, vitamin B<sub>12</sub> is a complex of cobalt.

- 18. Compounds that contain at least one carbon-metal bond are called organometallic compounds. Organometallic compounds may be classified in three classes:
  - (a) Sigma ( $\sigma$ ) bonded complexes (b) pi ( $\pi$ ) bonded complexes (c) complexes containing both  $\sigma$  and  $\pi$ -bonding.

Grignard reagent (R—Mg—X), zinc compound: ( $R_2$ Zn), Al<sub>2</sub>(CH<sub>3</sub>)<sub>6</sub>, etc., are σ-bonded organometallic compounds. Zeise's salts, ferrocene, dibenzene chromium are  $\pi$ -bonded complexes. Metal carbonyls are examples of both  $\sigma$  and  $\pi$ -bonded organometallic compounds.

- 19. (a) Ligands with more than six donor groups form unstable rings due to steric hindrance.
  - (b) Chelating ligands form more stable complexes than the monodentate ligands. Chelates with five membered rings including metal atom are more stable if these do not contain double bonds. Chelates with six membered rings are more stable if the ligands contain conjugate double
  - (c) Complex formed with a cyclic polydentate ligand is more stable than complex formed with a non-cyclic ligand.
- **20.** (a) The complexes of the type  $MA_3B_3$  can form the following two types of geometrical isomers:

$$\begin{array}{c|c} NH_3 \\ H_3N & - & Cl \\ \hline \\ H_3N & - & Cl \\ \end{array}$$

Facial or fac-isomer

All the similar ligands occupy the same face of the octahedron.

$$H_3N_{\square}$$
  $C_1$   $C_1$   $C_2$   $C_3$   $C_4$   $C_4$   $C_5$   $C_6$   $C_1$ 

Meridional or mer-isomer

(b) In square planar complexes, positions, 1,2; 2,3; 3,4 and 1,4 are cis while 1,3 and 2,4 are trans with respect to each other. In octahedral complexes, positions 1,2; 1,3; 1,4 and 1,5 are cis while 1,6; 2,4 and 3,5 are trans with respect to each other.

Square planar

21. (a) Ferrocene  $[Fe(\eta^5 - C_5H_5)_2]$  and dibenzene chromium  $[Cr(\eta^6 - C_6H_6)_2]$  are called sandwiched compounds.

- (b) Potassium hexanitrocobaltate(III), K<sub>3</sub>[Co(NO<sub>2</sub>)<sub>6</sub>] is called Fischer's salt.
- (c) Haemoglobin is a complex of Fe, chlorophyll is a complex of Mg and vitamin B<sub>12</sub> is a complex of Co.
- 22. (a) Organo-arsenic compounds are used as remedy for syphillis.
  - (b) Zeigler-Natta catalyst, R<sub>3</sub>Al, mixed with TiCl<sub>3</sub> or TiCl<sub>4</sub> is used in low temperature polymerisation of alkenes.
  - (c) Wilkinson's catalyst, (Ph<sub>3</sub>P)<sub>3</sub>RhCl is used in the hydrogenation of alkenes.
  - (d) Ethyl mercury chloride is used to prevent the infection of young plants.
  - Tetraethyl Lead (TEL) is an important anti-knock compound added to petrol used in interval combustion engines.
  - (f) Grignard reagent and several other organo metallics are good reagents for the synthesis of compounds.

# Subjective Type Questions

- 1. Indicate 'principal' and 'secondary' valencies of central metal ion in the following complexes:
  - (a)  $[Cr(NH_3)_6]Cl_3$
- (b)  $K_4[Fe(CN)_6]$
- (c)  $[Pt(NH_3)_2Cl_2]$
- (d)  $K_2[PtCl_4]$
- (e)  $[Co(NH_3)_5H_2O]Cl_3$
- (f) [Cu(NH<sub>3</sub>)<sub>4</sub>]SO<sub>4</sub>
- Determine the effective atomic number of the metal atom in the following:
  - (a)  $[Cr(CO)_6]$
- (c) [Co(CN)<sub>6</sub>]<sup>4</sup>
- (b) [Fe(CN)<sub>6</sub>]<sup>3-</sup> (d) [Ni(NH<sub>3</sub>)<sub>6</sub>]<sup>2+</sup>

[Cr = 24; Fe = 26; Co = 27 and Ni = 28 as atomic numbers]

- 3. Write down the IUPAC names of the following complexes:
  - (i)  $K_4[Mo(CN)_8]$
- (ii)  $Co[(en)_2Cl(ONO)]^+$
- (iii) [Cr(P·Ph<sub>3</sub>)(CO)<sub>5</sub>]
- (iv)  $[Pt(NH_3)_4Cl_2][PtCl_4]$
- (v) (NH<sub>4</sub>)<sub>3</sub>[Cr(NCS)<sub>6</sub>]

- (vi)
- (vii) K[BF<sub>4</sub>]
- (viii) Cu<sub>2</sub>[Fe(CN)<sub>6</sub>]
- Write the formulae of the following complexes:
  - (a) Diamminechlorido (ethylenediamine) nitrito-N-platinum (IV) chloride.
  - (b) Calcium hexacyanoferrate (II).
  - Tetraamminecobalt (III)-µ-amino-µ-nitrotetraamminecobalt (III) nitrate.
  - (d) Dichlorido bis (ethylenediamine) cobalt (III) sulphate.
  - Sodium tetrahydroxoaluminate (III).
  - Potassium ethylenediamine tetraacetate ferrate (II).
  - (g) Hexaammine chromium(III) hexacyanocobaltate(III).
- Combination of Pt(IV), NH<sub>3</sub>, Cl<sup>-</sup> and K<sup>+</sup> results in the formation of seven complexes and one such complex is [Pt(NH<sub>3</sub>)<sub>6</sub>]Cl<sub>4</sub>.

- (i) Write the formulae of the other six members of the
- (ii) Name these complexes according to the IUPAC system of nomenclature.
- (iii) Which will have highest molar conductivity?
- (iv) Which of these is non-ionic?
- (v) What is the coordination number and oxidation state of Pt in these complexes?
- How many ions per mole of the following complexes are present in their solutions?
  - (i)  $[Co(NH_3)(en)_2Cl]Cl_2$
- (ii)  $[Ag(NH_3)_2]Br$
- (iii) [Pt(NH<sub>3</sub>)<sub>4</sub>][PtCl<sub>4</sub>]
- (iv) [Pt(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]Cl<sub>2</sub>
- (v)  $Cu_2[Fe(CN)_6]$
- 7. Which of the following names are correct?
  - (i) K<sub>3</sub>[Fe(CN)<sub>5</sub>NO] : Potassium pentacyanonitrosyl ferrate (II).
  - (ii) Na<sub>2</sub> [Ni (EDTA)]: Sodium ethylenediamminetetraacetatonickel (I).
  - (iii) [Co(NH<sub>3</sub>)<sub>5</sub>CO<sub>3</sub>]Cl: Pentaamminecarbonatocobalt (III) chloride.
  - (iv)  $K_3[Al(C_2O_4)_3]$ : Potassium tris (oxalato) aluminate
  - (v)  $K_2[Zn(OH)_4]$
- : Potassium tetrahydroxozincate (II).
- (vi)  $K_2[PtF_6]$
- : Potassium hexafluoridoplatinate (IV).
- (vii) [Co(en)3]Cl3
- : Triethylenediamminecobalt (III)
- chloride.
- (viii) Hg[Co(CNS)<sub>4</sub>] : Mercury tetrathiocyanatocobalt (II).
- 8. What type of isomers are the following?
  - (i) [(CO)<sub>5</sub>MnSCN]
- and [(CO)<sub>5</sub>MnNCS]
- (ii)  $[Co(en)_3][Cr(CN)_6]$
- and [Cr(en)<sub>3</sub>] [Co(CN)<sub>6</sub>]
- (iii) [Co(NH<sub>3</sub>)<sub>5</sub>NO<sub>3</sub>]SO<sub>4</sub>
- and [Co(NH<sub>3</sub>)<sub>5</sub>SO<sub>4</sub>]NO<sub>3</sub>
- (iv)  $[Co(py)_2(H_2O)_2Cl_2]Cl$  and  $[Co(py)_2(H_2O)Cl_3]H_2O$
- Describe a simple chemical test that would allow you to distinguish between the compounds, [Co(NH<sub>3</sub>)<sub>5</sub>Br]SO<sub>4</sub> and [Co(NH3)5SO4]Br.
- 10. How many geometrical isomers are there for:
  - (a) [Co(NH<sub>3</sub>)<sub>2</sub>Cl<sub>4</sub>], octahedral?
  - (b) [AuCl<sub>2</sub>Br<sub>2</sub>], square planar?
  - (c)  $[CoCl_2Br_2]^{2-}$ , tetrahedral?
- 11. What are the types of hybridization involved in the following geometrical shapes of the complex?
  - (a) Square planar
- (b) Tetrahedral
- (c) Octahedral
- 12. Explain the geometry and magnetic nature of the following complex ions on the basis of valence bond theory.
  - (i)  $[Cr(NH_3)_6]^{3+}$
- (iii)  $[FeF_6]^{3-}$

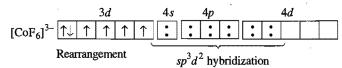

- (iv)  $[MnCl_4]^2$
- (ii) [Fe(CN)<sub>6</sub>]<sup>4-</sup> (v) [Ni(CN)<sub>4</sub>]<sup>2-</sup>
- (vi)  $[Cu(NH_3)_4]^{2+}$
- 13. Explain the following:
  - (i) All the octahedral complexes of Ni<sup>2+</sup> must be outerorbital complexes.

[Ans. 3d $Ni^{2+}$  configuration  $\uparrow \downarrow \uparrow \downarrow \uparrow \downarrow \uparrow \downarrow \uparrow \uparrow \uparrow$ 

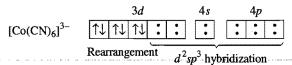

During rearrangement only one 3d-orbital may be made available by pairing the electrons. Thus, inner  $d^2sp^3$ 

hybridization is not possible. So, only  $sp^3d^2$  (outer) hybridization can occur.]

 $[CoF_6]^{3-}$  is paramagnetic but  $[Co(CN)_6]^{3-}$  is diamagnetic. [Ans. In  $[CoF_6]^{3-}$ ,  $Co^{3+}$  undergoes  $sp^3d^2$  hybridization. Four d-orbitals are singly occupied. Hence, it is paramagnetic.

In  $[Co(CN)_6]^{3-}$ ,  $Co^{3+}$  undergoes  $d^2sp^3$  hybridization. No-orbital is singly occupied. Hence, it is diamagnetic.]

(iii) The magnetic moment of [MnCl<sub>4</sub>]<sup>2</sup> is 5.92 B.M. [Ans. In [MnCl<sub>4</sub>]<sup>2-</sup> ion, Mn<sup>2+</sup> ion undergoes sp<sup>3</sup> hybridization. It contains 5d-orbitals singly occupied. Hence, it has high value of magnetic moment.]

(iv) NH<sub>4</sub> ion does not form complexes.

[Ans. NH<sub>4</sub><sup>+</sup> ion does not act as ligand because nitrogen atom has no lone pair of electrons which it can donate to metal atom.]

(v) (SCN) shows linkage isomerism in coordination compounds.

[Ans. (SCN) group can coordinate with metal atom either through S-atom or N-atom giving two isomers. Thus, it shows linkage isomerism.]

(vi) Three geometrical isomers of the square planar complex,  $[Pt(NH_3)(H_2O)(py)(NO_2)]^+$ , are possible. [Ans.

Three different arrangements corresponding to three geometrical isomers are possible.]

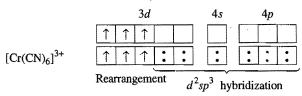

- 14. Find out the hybridization, geometry and magnetic moment of the complexes:
  - $[Co(MH_3)_6]^{34}$
- (ii) [Cr(CN)<sub>6</sub>]<sup>3</sup>-

[Ans. The oxidation state of cobalt in the complex is +3. The electronic configuration of Co<sup>3+</sup> ion is:

	34	d	4 <i>s</i>	4 <i>p</i>
	$\uparrow\downarrow$ $\uparrow$ $\uparrow$	1 1		
$[Co(NH_3)_6]^{3+}$	$\uparrow\downarrow\uparrow\uparrow\downarrow\uparrow$			
	Rearrangen	nent d2	sn <sup>3</sup> hyb	ridization

Octahedral, zero magnetic moment.

The oxidation state of chromium in the complex is +3. The electronic configuration of Cr<sup>3+</sup> ion is:

Octahedral, mag. moment =  $\sqrt{3 \times (3+2)} = \sqrt{15} = 3.87$  B.M.]

- 15. Draw the structures of  $[Co(NH_3)_6]^{3+}$ ,  $[Ni(CN)_4]^{2-}$  and  $Ni(CO)_4$ . Write the hybridization of atomic orbitals of the transition metal in each case. [I.I.T. 2000]
- Deduce the structures of [NiCl<sub>4</sub>]<sup>2-</sup> and [Ni(CN)<sub>4</sub>]<sup>2-</sup> considering the hybridization. Calculate the magnetic moment (spin only) of the species. [I.I.T. 2002]
   [Ans. In [NiCl<sub>4</sub>]<sup>2-</sup>, CI is weak field ligand.

$$Ni_{28} \longrightarrow 3d^{8}4s^{2}4p^{0}$$

$$Ni^{2+} \text{ in } \longrightarrow \qquad \uparrow \downarrow \uparrow \downarrow \uparrow \downarrow \uparrow \uparrow \qquad \vdots \qquad \vdots \qquad \vdots$$

$$[NiCl_{4}]^{2-} \qquad \qquad sp^{3} \text{ hybridization}$$

:.  $[NiCl_4]^{2-}$  is a tetrahedral complex. Number of unpaired electrons in  $Ni^{2+} = 2$ 

Magnetic moment ' $\mu$ ' =  $\sqrt{n(n+2)} = \sqrt{2(2+2)} = 2.82$  B.M. In [Ni(CN)<sub>4</sub>]<sup>2-</sup>, CN<sup>-</sup> is strong field ligand.

 $Ni^{4+}$  in  $\longrightarrow$   $T\downarrow T\downarrow T\downarrow T\downarrow$   $dsp^2$  hybridization

..  $[\text{Ni(CN)}_4]^{2-}$  is a square planar complex. Number of unpaired electrons in  $\text{Ni}^{2+} = 0$ Magnetic moment ' $\mu$ ' =  $\sqrt{n(n+2)} = 0$  ]

- 17. What are the main features of the ligand field theory?
- 18. How does crystal field theory explain?
  - (i) High spin and low spin states of complexes
  - (ii) Magnetism of complexes
  - (iii) Colour of the complexes.
- 19. (a) What are organometallic compounds? How are these compounds classified?
  - (b) How is ferrocene, Fe(C<sub>5</sub>H<sub>5</sub>)<sub>2</sub> prepared? Draw its structure.
- **20.** (a) Describe at least three applications of coordination compounds.
  - (b) Describe the applications of organometallic compounds in homogeneous catalysis.
- 21. What is meant by stability of a coordination compound in solution? State the factors which govern stability of complexes.

# Matching Type Questions

### Match the following:

- 1. Double salt
- 2. Zeise's salt
- 3. Neutral molecule
- 4. EDTA
- 5. Ni(CO)<sub>4</sub>
- 6.  $[Cr(NH_3)_6]^{3+}$
- 7. Low spin complex
- 8. Glycine

- (a)  $[Co(NH_3)_3Cl_3]$
- (b) Hexadentate...
- (c) Bidentate
- (d) Paramagnetic

Answers: Matching Type Questions

# ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. Highest molar conductivity is exhibited by:
  - (a) [Co(NH<sub>3</sub>)<sub>6</sub>]Cl<sub>3</sub>
- (b) [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]Cl
- (c) [Co(NH<sub>3</sub>)<sub>5</sub>Cl]Cl<sub>2</sub>
- (d) [Co(NH<sub>3</sub>)<sub>3</sub>Cl<sub>3</sub>]

Ans. (a)

[Hint: [Co(NH<sub>3</sub>)<sub>6</sub>]Cl<sub>3</sub> gives maximum number of ions in solution. Thus, it shows highest molar conductivity.  $[Co(NH_3)_6]Cl_3 \Longrightarrow [Co(NH_3)_6]^{3+} + 3Cl^{-}$ Total ions = 41

- The complex,  $[Co(NH_3)_4Cl_2]^+$  is known to exist in two different coloured forms. This is due to:
  - (a) ionisation isomerism
- (b) optical isomerism
- (c) geometrical isomerism
- (d) linkage isomerism

Ans. (c)

- 3. The IUPAC name of  $[Pt(NH_3)_4Cl_2][PtCl_4]$  is:
  - (a) tetraamminedichloridoplatinum (IV) tetrachloridoplatinate (III)
  - (b) tetraamminedichloridoplatinum (II) tetrachloridoplatinate (III)
  - (c) tetraamminedichloridoplatinum (III) tetrachloridoplatinate (II)
  - (d) tetraamminedichloridoplatinum (IV) tetrachloridoplatinate (II) Ans. (d)
- Which one of the following cyano complexes would exhibit the lowest value of paramagnetic behaviour?

[A.LE.E.E. 2005]

- (a)  $[Cr(CN)_6]^{3-}$
- (b) [Co(CN)<sub>6</sub>]
- (c)  $[Fe(CN)_6]^3$
- (d) [Mn(CN)<sub>6</sub>]

Ans. (b)

[Hint :  $Co^{3+}$ , E.C. = [Ar]  $3d^6$ 

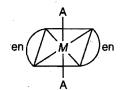

No unpaired electron paramagnetism = 0

- 5. In which of the following pairs both the complexes show optical isomerism? [A.I.I.M.S. 2005]
  - (a) cis-[Cr(C<sub>2</sub>O<sub>4</sub>)<sub>2</sub>Cl<sub>2</sub>]<sup>3-</sup>, cis-[Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]
  - (b) [Co(en)<sub>3</sub>]Cl<sub>3</sub>, cis-[Co(en)<sub>2</sub>Cl<sub>2</sub>]Cl

- (c) [PtCl (dien)]Cl, [NiCl<sub>2</sub>Br<sub>2</sub>]<sup>2-</sup>
- (d)  $[Co(NO_3)_3(NH_3)_3]$ , cis- $[Pt(en)_2Cl_2]$

Ans. (b)

Two complexes given below are:

- (a) geometrical isomers
- (b) position isomers
- (c) optical isomers
- (d) identical

Ans. (d)

[Hint: Both represent the same molecule.]

- 7. The number of geometrical isomers of  $[Co(NH_3)_3(NO_2)_3]$  are:
  - (a) 2

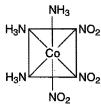

(b) 3

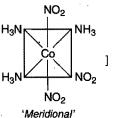

(c) 4

(d) nil

Ans. (a)

[Hint: The complex exhibits two geometrical isomers (i) facial and (ii) meridional.

- 'Facial' Which of the following is a  $\pi$ -acid ligand?
  - (a) NH<sub>3</sub>

(c) F

(d) H<sub>2</sub>N—CH<sub>2</sub>—CH<sub>2</sub>—NH<sub>2</sub>

Ans. (b)

[Hint: Ligands which are capable of accepting an appreciable amount of  $\pi$  electron density from the metal atom into  $\pi$ or  $\pi^*$  orbitals of their own are called  $\pi$ -acceptor or  $\pi$ -acid ligands such as CO.]

- **9.** Wilkinson's catalyst is:
  - (a) TiCl<sub>4</sub> and Al(C<sub>2</sub>H<sub>5</sub>)<sub>3</sub>
- (b)  $[(Ph_3P)_3RhCl]$
- (c) TiCl<sub>4</sub> and (C<sub>6</sub>H<sub>5</sub>)<sub>3</sub>P Ans. (a)
- (d) none of these
- 10. Which of the following systems has maximum number of unpaired electrons or maximum paramagnetism?
  - (a)  $d_{-}^{4}$  (octahedral)
- (c)  $d^7$  (octahedral)
- (b)  $d^9$  (octahedral) (d)  $d^5$  (octahedral)

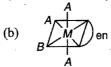

Ans. (d)

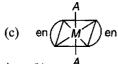

[Hint:  $d^5$  system has five unpaired electrons.]

- 11. The tetrahedral crystal field splitting is only . . . . of the octahedral splitting.
  - (a) 1/9
- (b) 2/9
- (c) 4/9
- (d) 5/9

- Ans. (c)
- 12. Which order is correct in spectrochemical series of ligands?
  - (a)  $Cl^{-} < F^{-} < [C_2O_4]^{2^{-}} < NO_2^{-} < CN^{-}$
  - (b)  $CN < [C_2O_4]^2 < Cl < NO_2 < F$
  - (c)  $[C_2O_4]^2 < F^- < Cl^- < NO_2^- < CN^-$
  - (d)  $F^- < Cl^- < NO_2^- < CN^- < [C_2O_4]^{2-}$
- 13. The phenomenon of optical activity will be shown by:

- Ans. (b)
- 14. The number of isomers possible for square planar complex, K<sub>2</sub>[PdClBr<sub>2</sub>SCN] are:
  - (a) 2

(b) 3

(c) 4

(d) 6

Ans. (c)

[Hint: Two geometrical isomers and two linkage isomers (-SCN

- 15. The pair in which both species have same magnetic moment (spin only value) is: [A.I.I.M.S. 2006]
  - (a)  $[Cr(H_2O)_6]^{2+}$ ,  $[CoCl_4]^{2-}$
  - (b)  $[Cr(H_2O)_6]^{2+}$ ,  $[Fe(H_2O)_6]^{2+}$
  - (c)  $[Mn(H_2O)_6]^{2+}$ ,  $[Cr(H_2O)_6]^{2+}$
  - (d)  $[CoCl_4]^{2-}$ ,  $[Fe(H_2O)_6]^{2+}$

Ans. (b)

[Hint: Same magnetic moment = Same number of unpaired electrons

$$=\sqrt{n(n+2)}$$

where n = number of unpaired electrons

 $Co^{2+} = 3d^7$ , 3 unpaired electrons

 $Cr^{2+} = 3d^4$ , 4 unpaired electrons  $Mn^{2+} = 3d^5$ , 5 unpaired electrons

 $Fe^{2+} = 3d^6$ , 4 unpaired electrons]

- 16. The pair in which both species have iron is: [A.I.I.M.S. 2006]
  - (a) nitrogenase, cytochromes
  - (b) carboxypeptidase, haemoglobin
  - (c) haemoglobin, nitrogenase
  - (d) haemoglobin, cytochromes Ans. (d)
- 17. The ligands in anticancer drug 'cis-platin' are:

[A.I.I.M.S. 2006]

- (a) NH<sub>3</sub>, Cl
- (b) NH<sub>3</sub>, H<sub>2</sub>O
- (c) Cl, H<sub>2</sub>O
- (d) NO, Cl

Ans. (a)

18. Match List-I with List-II and select the correct answer using codes given ahead in the lists:

LIST-1	List-II
Metal ions	Magnetic moments (B.M.)
A. Cr <sup>3+</sup>	1. √35
B. Fe <sup>2+</sup>	2. $\sqrt{30}$
C. Ni <sup>2+</sup>	3. $\sqrt{24}$
D. Mn <sup>2+</sup>	4. $\sqrt{15}$
	5 /6

- (a) A-1, B-3, C-5, D-4
- (b) A-2, B-3, C-5, D-1
- (c) A-4, B-3, C-5, D-1
- (d) A-4, B-5, C-3, D-1

[Hint: Magnetic moment =  $\sqrt{n(n+2)}$ 

$$Cr^{3+}$$
— $3d^3 = \sqrt{3 \times 5} = \sqrt{15}$   
 $Fe^{2+}$ — $3d^6 = \sqrt{4 \times 6} = \sqrt{24}$   
 $Ni^{2+}$ — $3d^8 = \sqrt{2 \times 4} = \sqrt{8}$   
 $Mn^{2+}$ — $3d^5 = \sqrt{5 \times 7} = \sqrt{35}$ 

- 19. In Fe(CO)<sub>5</sub>, the Fe-C bond possesses: [A.LE.E.E. 2006]
  - (a)  $\pi$  character only
- (b) σ character only
- (c) ionic character only
- (d) both  $\pi$  and  $\sigma$  characters

Ans. (d)

- **20.**  $[Cr(H_2O)_6]Cl_3$  (at. no. of Cr = 24) has a magnetic moment of 3.83 B.M. The correct distribution of 3d electrons in the chromium present in the complex is: [C.B.S.E. 2006]
  - (a)  $3d_{xy}^1$ ,  $3d_{yz}^1$ ,  $3d_{zx}^1$
  - (b)  $3d_{xy}^1$ ,  $3d_{yz}^1$ ,  $3d_{zz}^1$
  - (c)  $3d_{(x^2-v^2)}^1$ ,  $3d_{z^2}^1$ ,  $3d_{xz}^1$
  - (d)  $3d_{xy}^1$ ,  $3d_{(x^2-y^2)}^1$ ,  $3d_{yz}^1$

[Hint: Magnetic moment indicates that there are three unpaired electrons present in chromium. These must be present in lower energy orbitals which are  $3d_{xy}$ ,  $3d_{yz}$  and  $3d_{xz}$ .]

# **OBJECTIVE QUESTIONS**

**Note:** Choose the correct answer out of given alternatives for each question.

l.	Ethylenediamine is an example of a ligand.		(b) tetracarbonyl nickelate(II)	
	(a) monodentate $\Box$ (b) bidentate $\Box$		(c) tetracarbonyl nickel(0)	
	(c) tridentate $\Box$ (d) hexadentate $\Box$		(d) tetracarbonyl nickel(II)	
2.	How many EDTA molecules are required to make an	14.	The number of chloride ions which would be precipit	tated,
	octahedral complex with a Ca <sup>2+</sup> ion? [A.I.E.E.E. 2006]		when CrCl <sub>3</sub> ·4NH <sub>3</sub> is treated with silver nitrate solution	:
•	(a) Six $\Box$ (b) Three $\Box$		(a) 3	
	(c) One $\Box$ (d) Two $\Box$		(c) 1	
	[Hint: Only one molecule is required as EDTA is a hexadentate	15.	[Co(NH <sub>3</sub> ) <sub>5</sub> Br]SO <sub>4</sub> and [Co(NH <sub>3</sub> ) <sub>5</sub> SO <sub>4</sub> ]Br are related to	each
	ligand.]		other as:	
3.	The coordination number and oxidation number of $X$ in the		(a) ionisation isomers	
	given compound $[X(NH_3)_5(SO_4)]Cl$ will be:		(c) coordination isomers   (d) geometrical isomers	
	[Haryana (P.M.T.) 2006]	16.	[Co(NH <sub>3</sub> ) <sub>5</sub> NO <sub>2</sub> ]Cl <sub>2</sub> and [Co(NH <sub>3</sub> ) <sub>5</sub> ONO]Cl <sub>2</sub> are related to	each
	(a) 10 and 3		other as:	
	(c) 6 and 3		(a) geometrical isomers	
4.	Which one will give Fe <sup>3+</sup> ions in solution?		(c) coordination isomers $\Box$ (d) ionisation isomers	
	(a) $[Fe(CN)_6]^{3-}$	17.	Which of the following shows structural, geometrical	l and
	(b) $[Fe(CN)_6]^{2-}$		optical isomerism?	*
	(c) $(NH_4)_2SO_4 \cdot FeSO_4 \cdot 6H_2O$		(a) $[Co(en)(NH_3)_2Cl_2]Cl$	
	(d) $Fe_2(SO_4)_3$		(b) [Co(PPh <sub>3</sub> ) <sub>2</sub> (NH <sub>3</sub> ) <sub>2</sub> Cl <sub>2</sub> ]Cl	
5.	Which of the following is non-ionisable?		(c) $[Co(en)_3]Cl_3$	-📮
	(a) $Pt(NH_3)_2Cl_4$ $\Box$ (b) $Pt(NH_3)_3Cl_4$ $\Box$		(d) $[Co(en)_2Cl_2]Br$	
	(c) $Pt(NH_3)_4Cl_4$ $\Box$ (d) $Pt(NH_3)_6Cl_4$ $\Box$	18.	Which one of the following does not give a white preci	pitate
6.	What is the coordination number of Cr in $K_3Cr(ox)_3$ ?		with silver nitrate solution?	
	(a) 6		(a) $[Co(NH_3)_6]Cl_3$	
	(c) 4		(c) $[Co(NH_3)_4Cl_2]Cl_2$ $\square$ (d) $[Co(NH_3)_3Cl_3]$	. $\square$
7.	What is the oxidation state of iron in $K_4$ Fe(CN) <sub>6</sub> ?	19.	Which of the following has the highest molar conduc	tivity
	(a) 6		in solution?	
	(c) 3 $\square$ (d) 2 $\square$		(a) $[Pt(NH_3)_6]Cl_4$ $\Box$ (b) $[Pt(NH_3)_5Cl]Cl_3$	
8.	What is the value of $x$ in the $[Ni(CN)_4]^x$ complex ion?		(c) $[Pt(NH_3)_4Cl_2]Cl_2$	
	(a) +2	20.	Geometrical isomerism is found in coordination compo	ounds
	(c) 0		having coordination number:	
9.	A complex compound in which the oxidation number of metal		(a) 2	
	is zero: [C.E.T. (Karnataka) 2008]		(c) 4 (tetrahedral) $\Box$ (d) 6	
	(a) $[Ni(CO)_4]$ $\Box$ (b) $[Pt(NH_3)_4]Cl_2$ $\Box$ (c) $K_4[Fe(CN)_6]$ $\Box$ (d) $K_3[Fe(CN)_6]$ $\Box$	21.	Which one of the following will be able to show geome	
10.	12 1 702		isomerism? [B.V.(Pune)	
10.	The EAN of cobalt in the complex ion $[Co(en)_2Cl_2]^+$ is: (a) 27 $\Box$ (b) 36 $\Box$		(a) $MA_4$	닏
	(a) 27	200	(c) $MABCD$	
11.		22.	Optical isomerism is not shown by the complex:	
11.	sulphate is:	ŀ	(a) $[Cr(ox)_3]^{3-}$	닏
	(a) $[Co(en)_2SO_4]$ $\Box$ (b) $[Co(en)_3SO_4]$ $\Box$	'	(b) $[Co(en)_2Cl_2]^+$ (cis-form).	. 🔲
	(c) $[Co(en)_3]_2SO_4$ $\Box$ (d) $[Co(en)_3]_2(SO_4)_3$ $\Box$		(c) $[Co(en)_2Cl_2]^+$ (trans-form)	
12.	The IUPAC name for the complex $[Co(NH_3)_5(NO_2)]Cl_2$ is:		(d) $[Cr(en)_3]^{3+}$	
	[A.I.E.E.E. 2006]		ox=oxalate; en=ethylenediamine	
	(a) nitrito- <i>n</i> -pentaammine cobalt (III) chloride	23.	Theoretically, the number of geometrical isomers expect	ed for
	(b) nitrito- <i>n</i> -pentaammine cobalt (II) chloride		octahedral complex, [Mabcdef] is:	_
	(c) pentaammine nitrito- <i>n</i> -cobalt (II) chloride		(a) 0	
	(d) pentaammine nitrito-n-cobalt (III) chloride	,	(c) 12	
13.		24.	The IUPAC name of complex, $K_3[Al(C_2O_4)_3]$ is:	
	(a) tetracarbonyl nickelate(0)		(a) potassium alumino oxalate	
	•		(b) potassium trioxalatoaluminate(III)	

	'				
	(c) potassium aluminium(III) oxalate		37.	Which one of following high spin complexes has the largest	
	(d) potassium trioxalatoaluminate(VI)			C.F.S.E. (crystal field stabilisation energy):	
25.	The complex that violates the EAN is:			(a) $[Cr(H_2O)]^{3+}$	
	(a) potassium ferrocyanide			(c) $[Mn(H_2O)_6]^{2+}$	
	(b) potassium ferricyanide			[Hint: Cation with higher oxidation state has a larger value of	
	(c) tetracarbonyl nickel			C.F.S.E. and C.F.S.E. decreases with increase of the	
	(d) hexaammine cobalt(III) chloride		20	number of electrons.]	
26.	The hybridization in Ni(CO) <sub>4</sub> is:	_	ĺ	The complex having the molecular composition,	
	(a) $sp_3$ $\square$ (b) $sp_3^2$			$[\text{Co(NO}_2)_2(\text{SCN})(\text{en})_2]$ Br exhibits:	
	(c) $sp^3$			(a) linkage isomerism	
27.	$K_4[Fe(CN)_6]$ is called:		1	(c) cis-trans isomerism  (d) all of these	
	(a) potassium hexacyanoferrate(II)		ł	Which one is not an organometallic compound?	
	(b) potassium ferricyanate		1	(a) $RMgX$ $\Box$ (b) $(C_2H_5)_4Pb$ $\Box$	
	(c) potassium ferricyanide			(c) $(CH_3)_4Sn$ $\square$ (d) $C_2H_5ONa$ $\square$	
	(d) prussian blue		40.	The formula of the ferrocene is:	
28.	The hybridization of Fe in $K_3[Fe(CN)_6]$ is:			(a) $[(C_5H_5)_2Fe]$ $\Box$ (b) $[Fe(CN)_6]^{3-}$ $\Box$	
,	(a) $sp^3$ $\Box$ (b) $dsp^3$		l .	(c) $[Fe(CN)_6]^2$ $\Box$ (d) $[Fe(CO)_5]$ $\Box$	
	(c) $sp^3d^2$		41.	$\pi$ -bonding is not involved in:	
29.	The complex, [Ni(CN) <sub>4</sub> ] <sup>2-</sup> has:	_	1	(a) ferrocene □ (b) dibenzene chromium □ (c) Zeise's salt □ (d) Grignard reagent □	
	(a) linear structure $\Box$ (b) tetrahedral structure		42.	(c) Zeise's salt	
	(c) square planar structure		42.	(a) rhodium	
20	(d) octahedral structure			(c) aluminium	
30.	All ligands are:		43.	Arrange the following in order of decreasing number of	
	(a) Lewis acids		15.	unpaired electrons:	
31	Which of the following is paramagnetic?	<u></u>		(i) $[Fe(H_2O)_6]^{2+}$ (ii) $[Fe(CN)_6]^{3-}$	
51.	(a) Potassium ferrocyanide			(i) $[Fe(H_2O)_6]^{2+}$ (ii) $[Fe(CN)_6]^{3-}$ (iv) $[Fe(H_2O)_6]^{3+}$	
	(b) Potassium ferricyanide			(a) (i), (ii), (iii), (iv) $\square$ (b) (iv), (ii), (i), (iii) $\square$	
	(c) Hexaammine cobalt(III) chloride			(c) (ii), (iii), (i), (iv) $\square$ (d) (iv), (i), (ii), (iii) $\square$	
	(d) Tetracarbonyl nickel(0)			[Hint: (iv), (i), (ii) and (iii) have 5, 4, 1 and 0 number of unpaired	
32.	Among the following ions which one has the highest p	ara-	l	electrons respectively.]	
	magnetism?		44.	Which of the following systems has maximum number of	•
	(a) $[Cr(H_2O)_6]^{3+}$			unpaired electrons?	
	(c) $[Cu(H_2O)_6]^{2+}$		ļ	(a) $d^4$ (octahedral, low spin)	<u>-</u>
	[Hint: Larger the number of unpaired electrons, the more i	t has	der Alle Control	(b) $d^6$ (tetrahedral) $\Box$ (c) $d^6$ (octahedral, low spin) $\Box$	
	paramagnetism. The outer configurations are; $Cr^{3+}$ - $Fe^{2+}$ - $3d^6$ ; $Cu^{2+}$ - $3d^9$ ; $Zn$ - $3d^{10}$ ]	$-3d^{3}$ ;		(c) $d^6$ (octahedral, low spin) $\Box$ (d) $d^9$ (octahedral) $\Box$	
			45.	The IUPAC name of $K_3[Fe(CN)_6]$ is: [A.I.E.E.E. 2005]	
33.	Which one of the following is paramagnetic in nature?		43.	(a) potassium ferrocyanide	
	(a) $Ni(CO)_4$			(b) potassium ferricyanide	
	(c) $[NiCl_4]^{2-}$			(c) potassium hexacyanoferrate(II)	ĺ
34.	Which one of the following complexes is diamagnet	ic in		(d) potassium hexacyanoferrate(III)	1
	nature?		46.	The oxidation number of Pt in $[Pt(C_2H_4)Cl_3]^-$ is:	
	(a) $[Cr(NH_3)_6]^{3+}$			(a) $+1$ $\square$ (b) $+2$ $\square$	
	(c) $[Co(NH_3)_6]$ $\Box$ (d) $[Fe(H_2O)_6]^{2+}$			(c) $+3$ $\square$ (d) $+4$ $\square$	j
35.	Which of the following complexes does not have tetrahe	edral	47.	Amongst Ni(CO) <sub>4</sub> , [Ni(CN) <sub>4</sub> ] <sup>2-</sup> and [NiCl <sub>4</sub> ] <sup>2-</sup> :	
•	geometry?			(a) $Ni(CO)_4$ and $[NiCl_4]^{2-}$ are diamagnetic and $[Ni(CN)_4]^{2-}$	-
	(a) Ni(CO) <sub>4</sub> (diamagnetic)			is paramagnetic	]
	(b) [MnCl <sub>4</sub> ] <sup>2-</sup> (5 unpaired electrons)			(b) [NiCl <sub>4</sub> ] <sup>2</sup> and [Ni(CN) <sub>4</sub> ] <sup>2</sup> are diamagnetic and [Ni(CO) <sub>4</sub> ]	1
	(c) [Ni(CN) <sub>4</sub> ] <sup>2-</sup> (diamagnetic)		-	is paramagnetic	]
	(d) [NiCl <sub>4</sub> ] <sup>2-</sup> (2 unpaired electrons)			(c) Ni(CO) <sub>4</sub> and $[Ni(CN)_4]^{2-}$ are diamagnetic and $[NiCl_4]^{2-}$ is	3
36.	The complex $[Pt(NH_3)_4]^{2+}$ has structure.			paramagnetic $\square$	]
20,	(a) square planar			(d) Ni(CO) <sub>4</sub> is diamagnetic and $[NiCl_4]^{2-}$ and $[Ni(CN)_4]^{2-}$ are	3
	(c) pyramidal			paramagnetic	_

48.	Identify the complexes which are expected to be coloured:		(a) complex salt $\Box$ (b) double salt $\Box$
	(a) $[Ti(NO_3)_4]$		(c) normal salt $\Box$ (d) none of these $\Box$
	(c) $[Cr(NH_3)_6]^{3+}3Cl^-$	60.	Which of the following gives maximum number of isomers?
	[Hint: $\text{Ti}^{4+} = 3d^0$ ; $\text{Cu}^+ = 3d^{10}$ ; $\text{Cr}^{3+} = 3d^3$ ; $\text{V}^{3+} = 3d^2$ ]		[C.B.S.E. 2001]
49.	Vitamin B-12 contains:		(a) $[Co(NH_3)_4Cl_2]$ $\Box$ (b) $[Ni(en)(NH_3)_4]^{2+}$ $\Box$
	(a) cobalt		(c) $[Ni(C_2O_4)(en)_2]$ $\square$ (d) $[Cr(SCN)_2(NH_3)_4]^+$ $\square$
	(c) iron $\Box$ (d) nickel $\Box$	61.	Coordination number of Ni in $[Ni(C_2O_4)_3]^{4-}$ is:
50.	Find out the wrong statement for an octahedral complex:		[C.B.S.E. 2001]
	(a) An ion with $d^5$ configuration has one unpaired electron		(a) 3
	both in weak and strong fields.		(c) 4
	(b) A central metal ion with $d^8$ configuration has two	62.	Which of the following organometallic compounds is $\sigma$ and
	unpaired electrons.		$\pi$ bonded? [C.B.S.E. 2001]
	(c) An ion with $d^6$ configuration is diamagnetic in a strong		(a) $[\text{Fen}^5(\text{C}_5\text{H}_5)_2]$
	field.		(c) $[Co(CO)_5NH_3]^{2+}$ $\square$ (d) $[Al(CH_3)_3]$ $\square$
	(d) In $d^4$ , $d^5$ , $d^6$ and $d^7$ configurations, weak and strong field	63.	Which statement is incorrect? [C.B.S.E. 2001]
	complexes have different number of unpaired electrons.□		(a) Ni(CO) <sub>4</sub> —Tetrahedral, paramagnetic
	[Hint: A $d^5$ ion has 5 unpaired electrons in weak field.]		(b) $[Ni(CN)_4]^2$ —Square planar, diamagnetic
51.			* * * * * * * * * * * * * * * * * * *
	(a) $Na_2[CuCl_4]$ $\square$ (b) $Na_2[CdCl_4]$ $\square$		(c) [Ni(CO) <sub>4</sub> ]—Tetrahedral, diamagnetic
			(d) $[NiCl_4]^{2-}$ —Tetrahedral, paramagnetic
		64.	Which of the following cannot show linkage isomerism?
52.	The number of geometrical isomers of [Co(NH <sub>3</sub> ) <sub>3</sub> (NO <sub>3</sub> ) <sub>3</sub> ] is:		[D.C.E. 2001]
	$\begin{array}{cccc} \text{(a) } 0 & & \Box & \text{(b) } 2 & & \Box \\ \text{(c) } 2 & & \Box & \text{(d) } 4 & & \Box \end{array}$		(a) $NO_2^-$
52	(c) 3		(c) $CN^-$
53.	The total number of possible isomers of the compound,	65.	Consider the following complex;
	$[Cu(NH_3)_4][PtCl_4]$ , are:		[Co(NH <sub>3</sub> ) <sub>5</sub> CO <sub>3</sub> ]ClO <sub>4</sub>
	(a) 3		the coordination number, oxidation number, number of $d$
	(c) 4		electrons and number of unpaired $d$ electrons on the metal
54.	The geometry of Ni(CO) <sub>4</sub> and Ni(PPH <sub>3</sub> ) <sub>2</sub> Cl <sub>2</sub> are:		are respectively: [S.C.R.A. 2001]
	(a) both square planar		(a) $6, 3, 6, 0$
	(b) tetrahedral and square planar respectively □	1	(c) $7, 1, 6, 4$
	(c) both tetrahedral	66.	In electroplating of copper, K [Ag(CN) <sub>2</sub> ] is used instead of
	(d) square planar and tetrahedral respectively		AgNO <sub>3</sub> . The reason is: [C.B.S.E. 2002]
55.	What is the shape of Fe(CO) <sub>5</sub> molecule? [C.B.S.E. 2000]		(a) a thin layer of Ag is formed on Cu
	(a) Tetrahedral		(b) more voltage is required
	(c) Trigonal bipyramidal □ (d) Square pyramidal □		(c) $Ag^+$ ions are completely removed from solution $\Box$
56.			(d) less availability of Ag <sup>+</sup> ions, as Cu cannot displace Ag
	occurring extensively in living world? [C.B.S.E. 2000]		from $[Ag(CN)_2]^-$ ion
	(a) Haemoglobin	67.	
	(c) Florigen		[C.E.T. (Chandigarh) 2002]
57.	The complex ion which has no $d$ electrons in the central metal		(a) $[Co(en)_2Cl_2]^+$
	atom is (At. No. $Cr = 24$ , $Mn = 25$ , $Fe = 26$ , $Co = 27$ ):		(c) $[Co(NH_3)_4Cl_2]^+$
	[I.I.T. (S) 2001]	68.	In $[Cr(C_2O_4)_3]^{3-}$ , the isomerism shown is:
	(a) $[MnO_4]^-$		[A.I.E.E.E. 2002]
	(c) $[Fe(CN)_6]^{3-}$ $\Box$ (d) $[Cr(H_2O)_6]^{3+}$ $\Box$		(a) ligand $\Box$ (b) optical $\Box$
58.	The correct order of hybridization of the central atom in	1	(c) geometrical $\Box$ (d) ionisation $\Box$
	following species NH <sub>3</sub> , [PtCl <sub>4</sub> ] <sup>2-</sup> , PCl <sub>5</sub> , BCl <sub>3</sub> is (At. No. of	69.	Atomic numbers of Cr and Fe are respectively 25 and 26,
	Pt = 78): [L1.T. (S) 2001]	.	which of the following is paramagnetic with spin of electron?
	(a) $dsp^2$ , $dsp^3$ , $sp^2$ and $sp^3 \square$ (b) $sp^3$ , $dsp^2$ , $dsp^3$ , $sp^2 \square$		[C.B.S.E. 2002]
			(a) $Cr(CO)_6$
ξO	(c) $dsp^2$ , $sp^2$ , $dsp^3$ , $sp^3$ $\Box$ (d) $dsp^2$ , $sp^3$ , $sp^2$ , $dsp^3$ $\Box$		(c) $[Fe(CN)_6]^{4-}$
59.	e e	70.	The hypothetical complex chlorodiaquatriammine cobalt (III)
	give test for one of them in solution. Such salts are:		chloride can be represented as : [C.B.S.E. 2002]

		_	•
	(a) $[CoCl(NH_3)_3(H_2O)_2]Cl_2$	81.	The complex used as an anticancer agent is:
	(b) $[Co(NH_3)_3H_2OCl_3]$		[A.I.I.M.S. 2003; B.H.U. 2007]
	(c) $[Co(NH_3)_3(H_2O)Cl]$ $\Box$ (d) $[Co(NH_3)_3(H_2O)_3Cl_3]$ $\Box$		(a) $mer$ -[Co(NH <sub>3</sub> ) <sub>3</sub> Cl <sub>3</sub> ] $\square$ (b) $cis$ -[PtCl <sub>2</sub> (NH <sub>3</sub> ) <sub>2</sub> ] $\square$
71.	The type of isomerism present in nitropentaammine		(c) $cis$ - $K_2[PtCl_2Br_2]$ $\square$ (d) $Na_2[CoCl_4]$ $\square$
	chromium (III) chloride is: [A.I.E.E.E. 2002]	82.	The ligand called $\pi$ -acid is: [A.I.I.M.S. 2003]
	(a) optical		(a) CO $\Box$ (b) NH <sub>3</sub> . $\Box$

# **Objective Questions for IIT ASPIRANTS**

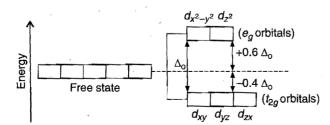

- The coordination number and oxidation number of M in the complex, [M(NH<sub>3</sub>)<sub>5</sub>SO<sub>4</sub>]Cl are:
  - (a) 10,3
- (b) 6,4
- (c) 2, 6
- (d) 6.3
- 2. CuSO<sub>4</sub>·5H<sub>2</sub>O is a coordination compound. It can be represented as:
  - (a)  $[Cu(H_2O)_4]SO_4 \cdot H_2O$
- (b) [Cu(H<sub>2</sub>O)<sub>3</sub>]SO<sub>4</sub>·2H<sub>2</sub>O
- (c)  $[Cu(H_2O)_2]SO_4:3H_2O$
- (d)  $[Cu(H_2O)_5]SO_4$
- The complex/complex ion, which shows optical activity is:
  - (a) [Cr(H<sub>2</sub>O)<sub>4</sub>Cl<sub>2</sub>]<sup>†</sup>
- (b) [Co(H<sub>2</sub>O)<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>]<sup>+</sup>
- (c) [Co(NH<sub>3</sub>)<sub>6</sub>]
- (d) [Co(CN)5NC]

[Hint:

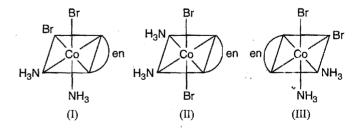

4.

The above splitting of d-orbitals takes place in the formation of:

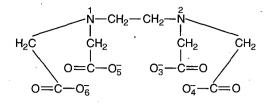

- (a) tetrahedral complexes
- (b) square-planar complexes

- (c) octahedral complexes
- (d) both tetrahedral and square-planar complexes
- 5. Which of the following pairs of complexes are isomeric with each other but their aqueous solutions exhibit different molar conductivities?
  - (a)  $[PtCl_2(NH_3)_4] Br_2$ and [Pt(NH<sub>3</sub>)<sub>4</sub>Br<sub>2</sub>] Cl<sub>2</sub>
  - (b) [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>] NO<sub>2</sub> [Co(NH<sub>3</sub>)<sub>4</sub>CINO<sub>2</sub>] CI and
  - [Co(NH<sub>3</sub>)<sub>5</sub>ONO] Cl<sub>2</sub> (c)  $[Co(NH_3)_5NO_2]Cl_2$ and
  - [Co(NH<sub>3</sub>)<sub>5</sub>SO<sub>4</sub>] Br (d) [Co(NH<sub>3</sub>)<sub>5</sub>Br] SO<sub>4</sub> and
  - [Hint: They are ionisation isomers but their molar conductivities are different due to different magnitude of charge on the cation and anion.]
- Three arrangements are shown for the complex, [Co(en)(NH<sub>3</sub>)<sub>2</sub>Br<sub>2</sub>]<sup>+</sup>. Which one is the wrong statement?

- (a) I and II are geometrical isomers
- (b) II and III are optical isomers
- (c) I and III are optical isomers
- (d) II and III are geometrical isomers
- 7. The donor sites of EDTA ligand are:
  - (a) O atoms only
  - (b) N atoms only
  - (c) two N atoms and four O atoms
  - (d) three N atoms and three O atoms

[Hint: The structure of EDTA ion is:

1, 2 are donor N atoms and 3, 4, 5, 6 are donor O atoms.]

- **8.** Which of the following can act as ligand but does not have any lone or unshared pair of electrons?
  - (a)  $C_2H_4$

(b) NH<sub>3</sub>

(c) H<sub>2</sub>O

(d) Cl<sup>-</sup>

[Hint:  $C_2H_4$  does not possess an unshared lone pair but it can act as  $\pi$ -acid ligand.]

9. A complex is prepared by mixing CoCl<sub>3</sub> and NH<sub>3</sub>. 0.1 *M* solution of the complex was found to freeze at -0.372°C. The formula of the complex is:

[Molal depression constant of water = 1.86°C/m]

- (a) [Co(NH<sub>3</sub>)<sub>6</sub>]Cl<sub>3</sub>
- (b) [Co(NH<sub>3</sub>)<sub>5</sub>Cl]Cl<sub>2</sub>
- (c) [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]Cl
- (d)  $[Co(NH_3)_3Cl_3]$

[Hint:

 $\Delta T_f = i \times K_f \times m = i \times 1.86 \times 0.1$ 

or  $0.372 = 0.186 \times i$ 

or i = 2

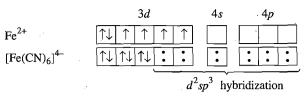

This shows that the complex gives two ions in solution. Thus, the formula of the complex is  $[Co(NH_3)_4Cl_2]Cl$ .  $[Co(NH_3)_4Cl_2]$   $Cl \rightleftharpoons [Co(NH_3)_4Cl_2]^+ + Cl^-$ 

- 10. Which statement is wrong?
  - (a) All the octahedral complexes of Ni<sup>2+</sup> are outer orbital complexes
  - (b) (SCN) shows linkage isomerism in coordination compounds
  - (c) All ligands are Lewis bases
  - (d) NH<sub>4</sub> ion can act as a ligand

[Hint: NH<sub>4</sub><sup>+</sup> ion does not act as ligand because nitrogen atom has no lone pair of electrons which it can donate to metal atom.]

- 11. Which of the following is correct?
  - (a) The IUPAC name of Mn<sub>3</sub>(CO)<sub>12</sub> is dodecacarbonyl trimanganese (0)
  - (b) The IUPAC name of  $K[BF_4]$  is tetrafluoroboron potassium (I)
  - (c) The IUPAC name of  $K_3[Al(C_2O_4)_3]$  is potassium trioxalate aluminium (III)
  - (d) The IUPAC name of K<sub>4</sub>[Fe(CN)<sub>6</sub>] is potassium ferrocyanide
- 12. Which of the following is not correct?
  - (a)  $[Fe(CN)_6]^{3-}$  is weakly paramagnetic
  - (b) [Fe(CN)<sub>6</sub>]<sup>4</sup> is strongly paramagnetic
  - (c) [Ni(CN)<sub>4</sub>]<sup>2-</sup> is diamagnetic
  - (d) [NiCl<sub>4</sub>]<sup>2-</sup> is paramagnetic

[Hint:  $[Fe(CN)_6]^4$  involves  $d^2sp^3$  hybridization. As CN<sup>-</sup> is a strong ligand, the pairing of electrons occurs, thus, it is a diamagnetic ion.

All orbitals are doubly occupied.]

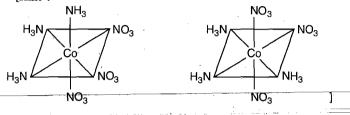

- 13. The number of geometrical isomers of  $[Co(NH_3)_3(NO_3)_3]$  are:
  - (a) 0

(b) 2

(c) 3

(d) 4

Hint:

Cis-form

Trans-form

- 14. The complex ion which has no d electron in the central metal atom is: [At. No. Cr = 24, Mn = 25, Fe = 26, Co = 27]
  - (a)  $MnO_4$
- (b)  $[Co(NH_3)_6]^{34}$
- (c)  $[Fe(CN)_6]^{3-}$
- (d)  $[Cr(H_2O)_6]^{3+}$
- **15.** In  $[Cr(C_2O_4)_3]^{3-}$ , the isomerism shown is :
  - (a) ligand
- (b) geometrical
- (c) optical
- (d) ionisation
- **16.**  $[Fe(H_2O)_6]^{2+}$  and  $[Fe(CN)_6]^{4-}$  differ in :
  - (a) geometry, magnetic moment
    - (b) magnetic moment, colour
    - (c) geometry, hybridization
    - (d) hybridization, number of unpaired electrons

[Hint:  $[Fe(H_2O)_6]^{2+}$  is paramagnetic while  $[Fe(CN)_6]^{4-}$  is diamagnetic.  $[Fe(H_2O)_6]^{2+}$  has pale green colour while  $[Fe(CN)_6]^{4-}$  has yellow colour.]

- 17. Complexes formed in the following methods are:
  - (i) cyanide process for extraction of silver
  - (ii) Mond's process for extraction of nickel
  - (iii) photographic fixing process
  - (iv) removal of Ca<sup>2+</sup> ions from hard water by EDTA.

- **18.** Which of the following statements is not correct?
  - (a) Higher the charge density on the central ion, the greater is the stability of its complexes
  - (b) Chelating ligands form more stable complexes as compared to monodentate ligands
  - (c) The higher the oxidation state of the metal, the more stable is the complex
  - (d) The cyano and ammine complexes are less stable than those formed by halide ions

- 19. Match the correct organic ligands used for the estimation of Ni<sup>2+</sup>, Fe<sup>3+</sup> and Al<sup>3+</sup> ions.
  - (i) Dimethyl glyoxime
- (ii) 1, 10-phenanthroline
- (iii) 8-hydroxy quinoline
  - (I)
- (III)
- $A1^{3+}$ (a) (b)
- Ni<sup>2+</sup> A1<sup>3+</sup>

- (c)
- A1<sup>3+</sup>
- Fe<sup>3+</sup> (d)
- Ni<sup>2+</sup>
- The EAN of a metal carbonyl,  $M(CO)_r$  is 36. The atomic number of metal is 24. The value of x is :
  - (a) 6

(c) 4

(d) 3

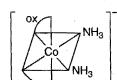

[Hint: EAN =  $36 = 2 \times x + 24$ ]

- **21.** *M*—*L* bonds in carbonyl possess :
  - (a) only sigma character
  - (b) only  $pi(\pi)$  character
  - (c) both sigma ( $\sigma$ ) and pi ( $\pi$ ) characters
  - (d) none of the above
- 22. The number of possible isomers of an octahedral complex,  $[Co(C_2O_4)_2(NH_3)_2]^{-1}$  is:
  - (a) 1

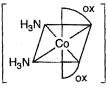

(b) 2

(c) 3

- (d) 4
- [Hint:

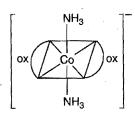

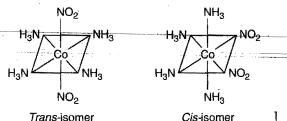

Cis-d-isomer

Cis-I-isomer

Trans-isomer

- 23.  $[Co(NH_3)_4(NO_2)_2]Cl$  exhibits:
  - (a) ionisation isomerism, geometrical isomerism and optical isomerism
  - (b) linkage isomerism, geometrical isomerism and optical isomerism
  - (c) linkage isomerism, ionisation isomerism and optical isomerism
  - (d) linkage isomerism, geometrical isomerism and ionisation isomerism
  - [Hint: (i) NO<sub>2</sub> is an ambidentate group. It can show linkage isomerism.
    - (ii) The complex can show ionisation isomerism with the complex [Co(NH<sub>3</sub>)<sub>4</sub>NO<sub>2</sub>Cl] NO<sub>2</sub>.
    - (iii) The complex shows geometrical isomerism.

Trans-isomer

Cis-isomer

- 24. When excess of ammonia is added to copper sulphate solution, the deep blue coloured complex is formed. The complex is:
  - (a) tetrahedral, paramagnetic
  - (b) tetrahedral, diamagnetic
  - (c) square planar, diamagnetic
  - (d) square planar, paramagnetic
  - [Hint:  $[Cu(NH_3)_4]^{2+}$  complex is formed by  $dsp^2$  hybridization and one electron is shifted to 4p-orbital.

 $dsp^2$ (square planar)]

1. (d) 2. (a) 3. (b) 4. (c) 5. (d) 6. (b) 7. (c) 8. (a) 9. (c) 10. (d) 11. (a) 12. (b) 17. (b) 22. (c) 13. (b) 14. (a) 15. (c) **16.** (b) 18. (d) 19. (c) 20. (a) 21. (c) 23. (d) 24. (d)

# Matrix Matching Questions for IIT Aspirants

## Coordination Compounds and Organometallic Compounds

Match the compounds in List-I with their classification in List-II:

### List-I

#### List-II

(a) LiAlH<sub>4</sub>

- (p) Reducing agent
- (b) KClMgCl2·6H2O
- (q) Double salt
- (c)  $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$
- (r) Alum
- (d) NaBH<sub>4</sub>

- (s) Complex hydride
- 2. Match the ligands in List-I with their classification in List-II:

#### List-I

#### List-II

(a) EDTA

(p) Monodentate

(b) DMG

- (q) Chelate ligand
- (c) Ethylenediammine (d) CN----
- (r) Bidentate (s) Hexadentate
- Match the complexes in List-I with their informations in List-II:

### List-I

#### List-II

- (a)  $[Cu(NH_3)_4]SO_4$
- (p)  $dsp^2$
- (b)  $[Pt(NH_3)_2Cl_2]$ (c)  $K_4[Fe(CN)_6]$
- (q) Octahedral (r)  $sp^3d^2$
- (d) [Fe(H<sub>2</sub>O)<sub>6</sub>]Cl<sub>3</sub>
- (s) Square planar
- 4. Match List-I with List-II: List-T

### List-II

- (a)  $d^2 s p^3$
- (p) Outer orbital octahedral complex
- (b)  $sp^{3}d^{2}$
- (q) High spin complex (r) Low spin complex
- (c) K<sub>3</sub>[Fe(CN)<sub>6</sub>] (d) [Fe(H<sub>2</sub>O)<sub>6</sub>]Cl<sub>3</sub>
- (s) Inner orbital octahedral complex
- 5. Match List-II with List-II: List-I

- (a) Ferrocene
- (b)  $Mn_2(CO)_{10}$
- (c) Vitamin B<sub>12</sub>
- (d) Heme

- List-II
- (p) Iron present
- (g) Cobalt -
- (r) Metal-metal bonding
- (s) Sandwich structure

6. Match List-II with List-II:

#### List-I

### List-II

- (a)  $[MnCl_6]^{2-}$
- (p) One unpaired electron
- (b)  $[Fe(CN)_6]^{3-}$
- (q)  $d^2sp^3$
- (c)  $[CoF_6]^{3-}$
- (r)  $sp^3d^2$
- (d)  $[Fe(H_2O)_6]^{2+}$
- (s) Four unpaired electrons
- 7. Match the complexes in the List-I with their coordination number in the List-II:

#### List-I

#### List-II

- (a)  $[Co(en)_3]^{3+}$
- (b)  $[Ca(EDTA)]^{2-}$
- (p) 6(q) 4
- (c) [Ni(CO)<sub>4</sub>]

- (r) 2
- (d) [Ag(NH<sub>3</sub>)<sub>2</sub>]Cl

- (e) [Fe(CO)<sub>5</sub>]
- Match the hybridization in List-I with its inference in complex
- compounds List-II:

### List-I

### List-II

(a) sp (b)  $sp^3$  (p) Octahedral (q) Tetrahedral

(c)  $sp^3d^2$ 

(r) Linear

(d)  $d^2sp^3$ 

- (s) Do not show geometrical
- isomerism Match the complexes in List-I with their stereoproperties in
- List-II:

### List-I

### (p) Show facial form

- (a)  $[CoCl_3(NH_3)_3]$ (b)  $[Cr(OX)_3]^{3-}$
- (q) Cis form is optically active

List-II

- (c)  $[CrCl_2(OX)_2]$
- (r) Trans form is optically inactive
- (d)  $[RhCl_3(Py)_3]$
- (s) Show meridian form
- Match the complexes in List-I with their properties listed in List-II: [I.LT. 2007]

#### List-I

### List-II

- (a)  $[Co(NH_3)_4(H_2O)_2]Cl_2$
- (b)  $[Pt(NH_3)_2Cl_2]$

- (d-r, s)(d-r)(d-p)
- -(e-s)
- (a-r, s) (b-q, s)(c-p) (a-p, s)(b-q, r) (c-q, r)
- **10.** (a-p, q, s) (b-p, r, s)
- (d-p, s)
  - (c-q, s)(d-q, s)

# **Assertion-Reason Type Questions**

The questions given below consist of Assertion (A) and **Reason** (R). Use the following key to select the correct answer:

- (a) If both (A) and (R) are correct and (R) is the correct explanation for (A).
- (b) If both (A) and (R) are correct but (R) is not correct explanation for (A).
- (c) If (A) is correct but (R) is incorrect.
- (d) If both (A) and (R) are incorrect.
- (e) If (A) is incorrect but (R) is correct.
- 1. (A) [Co(NH<sub>3</sub>)<sub>3</sub>Cl<sub>3</sub>] does not give a white precipitate with AgNO<sub>3</sub> solution.
  - (R) Chlorine is not present in the ionising sphere.
- (A) The ligands, thiocyanato (SCN) and isothiocyanato (NCS<sup>-</sup>) are ambidentate.
  - (R) The ligands form linkage isomers.
- (A) Ni(CO)<sub>4</sub> is diamagnetic in nature.
  - (R) Ni-atom undergoes  $sp^3$  hybridization.
- (A) Cis-isomer of [Co(en)<sub>2</sub>Cl<sub>2</sub>]Cl shows optical activity.
  - (R) Cis-isomer of [Co(en)<sub>2</sub>Cl<sub>2</sub>]Cl is a symmetric molecule.
- 5. (A) Complexes containing three bidentate groups such as  $[Cr(ox)_3]^{3-}$  and  $[Co(en)_3]^{3+}$  do not show optical activity.
  - (R) Octahedral complex, [Co(NH<sub>3</sub>)<sub>4</sub>Cl<sub>2</sub>]Cl shows geometrical isomerism.
- 6. (A) Tetrahedral complexes do not show geometrical iso-
  - (R) The relative positions of the ligands in the tetrahedral complex are the same w.r.t. each other.
- 7. (A) Ti(OC<sub>6</sub>H<sub>5</sub>)<sub>4</sub> is an organometallic compound.
  - (R) Acetate ion can form a chelate.
- (A) EAN of Cr in its complexes is always 36.
  - (R) Oxidation state of Cr in Cr(CO)<sub>6</sub> is zero.
- (A)  $K_3[Fe(CN)_6]$  is a low spin complex.
  - (R) Fe<sup>2+</sup> ion in this complex undergoes  $sp^3d^2$  hybridization.
- 10. (A) Coordination isomerism occurs when both cation and anion are complex.
  - (R) The complexes with coordination number 6 form octahedral complexes involving either  $sp^3d^2$  or  $d^2sp^3$ hybridization.

- 11. (A) Metals possess two types of valencies-primary and secondary. The primary valency is not ionisable while secondary valency is ionisable.
  - (R) The IUPAC name of K<sub>3</sub>[Fe(CN)<sub>6</sub>] is potassium ferricyanide.
- 12. (A) After splitting of d-orbitals during complex formation, the orbitals form two sets of orbitals  $t_{2p}$  and  $e_p$ .
  - (R) Splitting of d-orbitals occurs only in the case of strong field ligands such as CN-.
- 13. (A) Ferrocene is a  $\pi$ -bonded complex.
  - (R) All organometallic compounds are  $\pi$ -bonded complexes.
- 14. (A) All inner orbital complexes are diamagnetic.
  - (R) Inner orbital complexes contain only paired orbitals.
- 15. (A) Organometallic compounds are those which have one or more metal-carbon bonds.
  - (R) Metallic carbonyls are organometallic compounds having both  $\sigma$  and  $\pi$ -bonds.
- **16.** (A) In octahedral complexes, the three orbitals  $(d_{xy}, d_{yz}, d_{zx})$ are stable and of low energy while the two orbitals  $(d_{x^2-v^2}, d_{z^2})$  are unstable and have high energy.
  - (R) In octahedral complexes, the three d-orbitals  $(d_{xy}, d_{yz}, d_{zx})$ experience less repulsion from the ligands while two d-orbitals  $(d_{x^2-y^2}, d_{z^2})$  experience more repulsion from the ligands due to their shapes.
- 17. (A)  $[Co(NO_2)_3(NH_3)_3]$  does not show optical isomerism.
  - (R) It has a plane of symmetry.
- **18.** (A)  $[Fe(H_2O)_5NO]SO_4$  is paramagnetic.
  - (R) The Fe in [Fe(H<sub>2</sub>O)<sub>5</sub>NO]SO<sub>4</sub> has three unpaired electrons.

[Hint: Fe<sup>+</sup>-one electron from 4s is shifted to 3d i.e., it has  $3d^7$  configuration.

3 unpaired electrons]

- 19. (A) The geometrical isomers of the complex  $[M(NH_3)_4Cl_2]$  are optically inactive.
  - (R) Both geometrical isomers of the complex  $[M(NH_3)_4Cl_2]$ possess axis of symmetry.

# **HOUGHT TYPE QUESTIONS**

### THOUGHT 1

The neutral molecules, anions or cations which are directly linked with a central metal atom or ion in a complex are called ligands. A ligand is a species that is capable of donating an electron pair or pairs to the central metal atom or ion. It acts as a Lewis base. The ligands having two or more donor atoms are called polydentate or multidentate ligands. A multidentate ligand is known as a chelating ligand if on coordination it results in formation of a closed or cyclic ring. The complexes, thus, formed are known as chelates. Chelates are usually more stable.

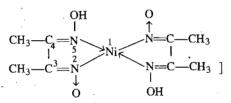

- 1. Which of the following ligands can form chelates?
  - (a) Ethylenediamine
- (b) Oxalic acid
- (c) Glycine
- (d) All of these
- How many donor sites are present in ethylenediamine tetraacetate ligand?
  - (a) 2

(b) 3

(c) 4

- (d) 6
- 3. Ni<sup>2+</sup> ion forms a scarlet red complex with DMG. It is a . . . . ... membered closed ring structure.
  - (a) 3
- (b) 4
- (c) 5
- (d) 6

[Hint: The structure of Ni-DMG complex is,

- 4. Which of the following is not a chelate?
  - (a) Cis-platin—a drug used in the treatment of cancer
  - (b) Haemoglobin—a protein present in blood
  - (c) Chlorophyll—a green plant pigment which acts as a photosensitizer in the synthesis of carbohydrates
  - (d) Vitamin B<sub>12</sub>—it is a cobalt (I) complex which is essential for growth of animals
- 5. Which of the following statements are correct about stability of chelates?
  - (a) As the number of rings in complex increases, stability of chelate also increases
  - (b) A chelate having five membered ring is more stable if it contains double bonds
  - (c) A chelate having six membered ring is more stable if it does not contain double bonds
  - (d) Chelating ligands are atleast bidentate ligands
- 6. Chelate effect refers to:
  - (a) increase in reactivity of complex because of chelation
  - (b) increase in stability of complex due to chelation
  - (c) increase in conductivity of complex due to chelation
  - (d) decrease in stability of complex due to chelation

### **THOUGHT 2**

Coordination compounds play a vital role in our lives. The importance of these compounds can be realised from the fact that life would not have been possible without the existence of chlorophyll in plants and haemoglobin in the blood of the animals. The field of such compounds has expanded very fast in recent years and coordination compounds are playing important roles in analytical chemistry, polymerisation reactions, metallurgy and refining of metals, organic synthesis, electroplating, biochemistry, water purification, textile dyeing and bacteriology.

- 1. The hardness of water is estimated by:
  - (a) Conductivity method
- (b) EDTA method
- (c) Titrimetric method
- (d) Distillation-method
- 2. A reagent used for identifying nickel ion is:
  - (a) Potassium ferrocvanide (b) Phenolphthalein
  - (c) Dimethyl glyoxime
- (d) EDTA
- 3. Lead poisoning in the body can be removed by:
  - (a) Zeise's salt
- (b) Ferrocene
- (c) Cis-platin
- (d) [Ca(EDTA)]<sup>2</sup>
- 4. Extraction of Ag from sulphide ore and removal of unreacted silver halide from photographic plate involve complexes:
  - (a)  $[Ag(CN)_2]^T$ ,  $[Ag(S_2O_3)_2]^{3-}$
  - (b)  $[Ag(S_2O_3)_2]^{3-}$ ,  $[Ag(CN)_2]^{-}$
  - (c) [Ag(CN)<sub>2</sub>] in both
- (d)  $[Ag(S_2O_3)_2]^{3-}$  in both
- Which is used in cancer chemotherapy?
  - (a) Cis-platin
- (b) Zeise's salt
- (c) Ferrocene
- (d) Fischer's salt

### THOUGHT 3

When crystals of CuSO<sub>4</sub> 4NH<sub>3</sub> are dissolved in water, there is hardly any evidence for the presence of Cu<sup>2+</sup> ions or ammonia molecules. A new ion, [Cu(NH<sub>3</sub>)<sub>4</sub>]<sup>2+</sup>, is furnished in which ammonia molecules are directly linked with the metal ion. Similarly, the aqueous solution of Fe(CN)2.4KCN does not give tests of Fe<sup>2+</sup> and CN ions but gives test of a new ion,  $[Fe(CN)_6]^4$ . The ions  $[Cu(NH_3)_4]^{2+}$  and  $[Fe(CN)_6]^{4-}$  are called complex ions. These ions are represented as:

$$\begin{bmatrix} NH_3 \\ \downarrow \\ H_3N \longrightarrow Cu \longleftarrow NH_3 \\ \uparrow \\ NH_3 \end{bmatrix}^{2+} ; \begin{bmatrix} NC & CN \\ NC \longrightarrow Fe \longleftarrow CN \\ NC & CN \end{bmatrix}^{4-}$$

- 1. The primary and secondary valency of copper in the complex Cu(NH<sub>3</sub>)<sub>4</sub>SO<sub>4</sub> are:
  - (a) 2, 4
- (b) 4, 2
- (c) 0, 4
- (d) 1, 4

2. The EAN of Fe in  $[Fe(CN)_6]^{4-}$  ion is :

(a) 24

(b) 30

(d) 38

3. The hybrid state of Cu in  $[Cu(NH_3)_4]^{2+}$  is:

(a)  $sp^3$ 

(b)  $sp^2d$ 

(c)  $sp^3d^2$ 

(d)  $dsp^2$ 

**4.**  $[Fe(CN)_6]^{4-}$  ion is:

- (a) square planar
- (b) octahedral
- (c) tetrahedral
- (d) none of these
- 5. Which one of the following statements is correct?
  - (a)  $[Cu(NH_3)_4]^{2+}$  is diamagnetic while  $[Fe(CN)_6]^{4-}$  is paramagnetic
  - (b)  $[Cu(NH_3)_4]^{2+}$  is paramagnetic while  $[Fe(CN)_6]^{4-}$  is diamagnetic
  - (c) Both are paramagnetic (d) Both are diamagnetic
- **6.** For a complex ion,  $[Cu(NH_3)_4]^{2+}$ :
  - (a) stability constant is  $[Cu(NH_3)_4]^{2+}/[Cu^{2+}][NH_3]^4$
  - (b) stability constant is  $[Cu^{2+}][(NH_3)_4]/[Cu(NH_3)_4]^{2+}$
  - (c) stability is more if instability constant is higher
  - (d) stability is less if stability constant is higher

# THOUGHT 4

The coordination number of Ni<sup>2+</sup> is 4.

 $NiCl_2 + KCN \longrightarrow A$  (Cyano complex)

 $NiCl_2 + Conc. HCl (excess) \longrightarrow B (Chloro complex)$ 

- 1. The IUPAC names of A and B are:
- [I.I.T. 2006]
- (a) Potassium tetracyanonickelate(II), potassium tetrachloridonickelate (II)

- (b) Tetracyanopotassiumnickelate (II), tetrachloridopotassiumnickelate(II)
- (c) Tetracyanonickel(II), tetrachloridonickel (II)
- (d) Potassium tetracyanonickel(II), potassium tetrachloridonickel(II)
- 2. Predict the magnetic nature of A and B:
  - (a) both are diamagnetic
  - (b) A is diamagnetic and B is paramagnetic with one unpaired
  - (c) A is diamagnetic and B is paramagnetic with two unpaired electrons
  - (d) both are paramagnetic
- 3. The hybridization of A and B are:

(a)  $dsp^2$ ,  $sp^3$ 

(c)  $dsp^2$ ,  $dsp^2$ 

(d)  $sp^3d^2$ ,  $d^2sp^3$ 

[Hint: Cyano complex K<sub>2</sub>[Ni(CN)<sub>4</sub>]

Potassium tetracyanonickelate (II)

Chloro complex K2[NiCl4]

Potassium tetrachloridonickelate(II)

3dCyano complex

> $dsp^2$ diamagnetic

Chloro complex

3d

# BRAIN STORMING PROBLEMS

- 1. Write down the IUPAC names of the following complexes:
  - (i)  $(NH_4)_2[FeF_5H_2O]$
  - (ii)  $[Co(NH_3)_5H_2O](ReO_4)_3$
  - (iii)  $[Co(H_2O)(NH_3)_5][Co(C_2O_4)_3]$
  - (iv)  $[Co(H_2O)(NH_3)_5][Cr(SCN)_4(NH_3)_2]_3$
  - (v)  $[Co(H_2O)(NH_3)_5][Co(NO_2)_4(NH_3)_2]_3$
  - (vi)  $K_4[Mo(CN)_8]$
- (vii)  $(NH_4)_2[Cr(NH_3)(NCS)(S)]$
- (viii)  $[Bi \{SC(NH_2)_2\}_2](SO_4)$  (ix)  $[(CH_3)_4N]_2[Co(NCS)_4]$
- 2. [V(CO)<sub>6</sub>] has a magnetic moment corresponding to one unpaired electron. Draw a valence bond structure for this molecule. What is geometrical structure of complex?
- 3. Indicate whether of the following complexes are low spin or high spin complexes:

- [Co(NH<sub>3</sub>)<sub>5</sub>Cl]Cl<sub>2</sub>
- 0 unpaired electron
- $K_4[Cr(CN)_6]$ [Pt(NH3)6]Cl4
- 2 unpaired electrons 0 unpaired electron
- (NH<sub>4</sub>)<sub>2</sub>[FeF<sub>5</sub>H<sub>2</sub>O]
- 5 unpaired electrons
- 4. Arrange the following complexes in increasing order of molar conductivity (on the basis of Werner's theory):
  - (a)  $K[Co(NH_3)_3(NO_2)_4]$
  - (b)  $[Cr(NH_3)_3(NO_2)_3]$
  - (c)  $[Cr(NH_3)_5(NO_2)_3][Co(NO_2)_6]_2$
  - (d) Mg[Cr(NH<sub>3</sub>)(NO<sub>2</sub>)<sub>5</sub>]
  - [Ans. (b) < (a) < (d) < (c)]
- 5. Write down the formula corresponding to the following IUPAC names.
  - (i) Aluminium tetrachloridoaurate(III)

- (ii) Diamminesilver(I) hexacvanoferrate(II)
- (iii) Tetrahydroxodiaquoaluminate(III) ion
- (iv) Hexaamminecobalt(III) tetrachloridodiammine chromate(III)
- (v) Hexaamminenickel(II) hexanitrocobaltate(III)

[Ans. (i) Al[AuCl<sub>4</sub>]<sub>3</sub>

- (ii) [Ag(NH<sub>3</sub>)<sub>2</sub>]<sub>4</sub>[Fe(CN)<sub>6</sub>]
- (iii)  $[Al(H_2O)_2(OH)_4]^-$  (iv)  $[Co(NH_3)_6][Cr(NH_3)_2Cl_4]_3$
- (v)  $[Ni(NH_3)_6]_3[Co(NO_2)_6]_2$
- **6.** How many geometrical isomers are possible for each of the following complexes? Draw the structure of each isomer:
  - (a)  $Pt(NH_3)_2(SCN)_2$
- (b) [CoCl<sub>2</sub>Br<sub>2</sub>]<sup>2-</sup>tetrahedral
- (c)  $Co(NH_3)_3(NO_2)_3$
- (d) Pt(en)Cl<sub>2</sub>
- (e)  $\left[\operatorname{Cr}(\operatorname{en})_2\operatorname{Br}_2\right]^+$
- $(f_{\bullet}) [Rh(en)_3]^{3+}$

[Ans. (a) Two (b) None (c) Two (d) None (e) Two (f) None]

- 7. Which of the following complexes can exist as optical isomers (enantiomers)? Draw the structure of each enantiomer:
  - (a)  $[Fe(C_2O_4)_3]^{3-}$
- (b)  $[Co(NH_3)_4(en)]^{34}$
- (c)  $[Co(NH_3)_2(en)_2]^{3+}$
- (d)  $[Cr(H_2O)_4Cl_2]^{24}$

**8.**  $[Fe(CN)_6]^{3-}$  ion has magnetic moment of 1.41 B.M. while  $[Fe(H_2O)_6]^{3+}$  has a magnetic moment of 5.92 B.M. Explain.

[Ans.  $[Fe(CN)_6]^3$  has one unpaired electron  $(d^2sp^3)$  hybridization of  $Fe^{3+}$ ) while  $[Fe(H_2O)_6]^{3+}$  has five unpaired electrons  $(sp^3d^2)$  hybridization of  $Fe^{3+}$ ,

[Fe(CN)<sub>6</sub>]<sup>3-</sup>

Mag. moment =  $\sqrt{2}$  = 1.414 B.M.

 $[Fe(H_2O)_6]^{3+}$ 

Mag. moment =  $\sqrt{5 \times 7} = \sqrt{35} = 5.92$  B.M.]

9. Match the geometry (given in column A) with the complex (given in column B).

(A)

(B)

- (i) Tetrahedral
- (a)  $[Cu(NH_3)_4]^2$
- (ii) Octahedral
- (b)  $[Ag(NH_3)_2]^{+}$
- (iii) Square planar
- (c) Fe(CO)<sub>5</sub>
- (iv) Trigonal bipyramidal
- (d)  $[Cr(H_2O)_6]^3$

- (v) Linear
- (e) [NiCL<sub>1</sub>]<sup>2</sup>-

[Ans. (i-e); (ii-d); (iii-a); (iv-c); (v-b)]

- 10. How many ions are given by the following complexes in aqueous solution?
  - (i) Ni(CO)<sub>4</sub>
- (ii) CoCl<sub>3</sub>·5H<sub>2</sub>O
- (iii) PtCl<sub>4</sub>·6NH<sub>3</sub>
- (iv) Cr(NH<sub>3</sub>)<sub>3</sub>(NO<sub>2</sub>)<sub>3</sub>

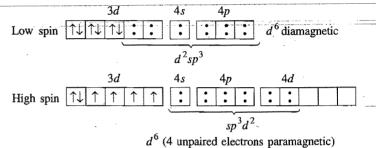

[Ans. (i) No ionisation

- (ii)  $[Co(H_2O)_5Cl] Cl_2 \rightleftharpoons [Co(H_2O)_5Cl]^{2+} + 2Cl^-$ ; three ions
- (iii)  $[Pt(NH_3)_6]Cl_4 \rightleftharpoons [Pt(NH_3)_6]^{4+} + 4Cl^-$ ; five ions
- (iv) [Cr(NH<sub>3</sub>)<sub>3</sub>Cl<sub>3</sub>] no ionisation]
- 11. What d electron configurations exhibit both high and low spin in octahedral complexes?

[Ans.  $d^4$ ,  $d^5$ ,  $d^6$ ,  $d^7$ ]

- 12. Depict high spin and low spin configurations for each of the following complexes. Tell whether each is diamagnetic or paramagnetic. Give the number of unpaired electrons for the paramagnetic complexes:
  - (a)  $[Fe(CN)_6]^{4-}$
- b) [Co(NH<sub>2</sub>)<sub>6</sub>]<sup>3+</sup>
- (c)  $[Fe(H_2O)_6]^{3+}$
- (d) [CrFa]<sup>4</sup>

[Ans. (a)  $[Fe(CN)_6]^{4-}$ :

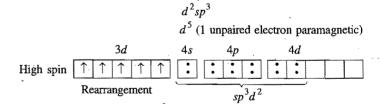

(b)  $\left[\text{Co(NH}_3)_6\right]^{3+}$ :  $d^6$  Case depiction as in (a)

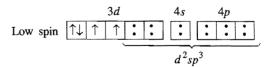

Low spin diamagnetic; high spin paramagnetic (4 unpaired electrons)

(c)  $[Fe(H_2O)_6]^{3+}$ :

Low spin

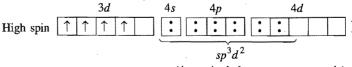

(d)  $[CrF_6]^{4-}$ :  $d^4$  Case

(2 unpaired electrons paramagnetic)

 $d^5$  (5 unpaired electrons paramagnetic)

(4 unpaired electrons paramagnetic)

13. Draw the structure of geometrical isomers of  $[Pt(gly)_2]$  where  $gly \rightarrow NH_2CH_2COO^-$ .

[Ans. 
$$CH_2 - NH_2$$
  $OC - O$   $OCO$ 

**14.** How many geometrical isomers with formula [MABCD] e.g., [Pt(NH<sub>3</sub>)(py)(NH<sub>2</sub>OH) NO<sub>2</sub>]<sup>+</sup> are possible?

[Ans. 3]

[Hint:

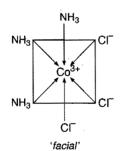

**15.**—Give the example of a tetrahedral complex showing optical activity.

**16.** What are *facial* and *meridional* isomers? Explain with examples.

[Ans. For the complexes of the type [Ma<sub>3</sub>b<sub>3</sub>] e.g., [Co(NH<sub>3</sub>)<sub>3</sub>Cl<sub>3</sub>] and [Rh(py)<sub>3</sub>Cl<sub>3</sub>]; the isomer is called facial (fac) when all similar ligands occupy same face of an octahedron as shown below. When all similar ligands are not on the same face then the isomer is called meridional (mer).

17. Explain why [Cu(en)<sub>2</sub>]<sup>2+</sup> is less stable than [Fe(EDTA)]<sup>-</sup>?

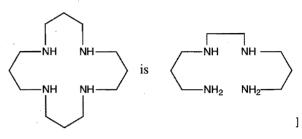

[Ans. [Cu(en)<sub>2</sub>]<sup>2+</sup> has four rings in the structure. On the other hand [Fe(EDTA)]<sup>-</sup> has five rings in the structure.

$$\begin{bmatrix} \mathsf{CH}_2 - \mathsf{NH}_2 & \mathsf{NH}_2 - \mathsf{CH}_2 \\ \mathsf{CH}_2 - \mathsf{NH}_2 & \mathsf{CU}^2 + \mathsf{NH}_2 - \mathsf{CH}_2 \\ \mathsf{CH}_2 - \mathsf{NH}_2 & \mathsf{CH}_2 \end{bmatrix}^{2+} \\ \begin{bmatrix} \mathsf{C} & \mathsf{C} & \mathsf{C} \\ \mathsf{C} & \mathsf{C} & \mathsf{C} \\ \mathsf{C} & \mathsf{C} & \mathsf{C} \\ \mathsf{C} & \mathsf{C} & \mathsf{C} \\ \mathsf{C} \\ \mathsf{C} & \mathsf{C} \\ \mathsf{C} & \mathsf{C} \\ \mathsf{C} \\ \mathsf{C} & \mathsf{C} \\ \mathsf{C} \\ \mathsf{C} & \mathsf{C} \\ \mathsf{C} \\ \mathsf{C} & \mathsf{C} \\ \mathsf{$$

Greater is the number of rings of chelation, more is the stability of complex. Thus, [Fe(EDTA)]<sup>-</sup> is more stable than [Cu(en)<sub>2</sub>]<sup>2+</sup>.]

18. What do you understand by macrocyclic effect?

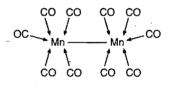

[Ans. Thermodynamic stability of a complex formed with a cyclic polydentate ligand is increased when compared to the complex formed with a non-cyclic ligand.

19. The EAN of each Mn(Z = 25) in  $Mn_2(CO)_{10}$  is 36. What is the structure of this complex?

[Ans. EAN = 25 (electrons from Mn atom) + 10 (electrons from five CO ligand) +1 (electron from Mn—Mn bond)

Thus, structure will be:

**20.** How many different structures are possible for each of the following complex ions?

(a)  $[Co(NH_3)_5H_2O]^{3+}$ 

(b)  $[Co(NH_3)_4(H_2O)_2]_0^{3+}$ 

(c)  $[Co(NH_3)_3(H_2O)_3]^{3+}$ 

(d)  $[Co(NH_3)_2(H_2O)_4]^{3+}$ 

[Ans. Draw the structures yourself.]

21. The hexaaqua complex,  $[Ni(H_2O)_6]^{2+}$ , is green, whereas the corresponding ammonia complex,  $[Ni(NH_3)_6]^{2+}$ , is violet. Explain.

[Ans. NH<sub>3</sub> is a stronger ligand than H<sub>2</sub>O, so [Ni(NH<sub>3</sub>)<sub>6</sub>]<sup>2+</sup> will absorb higher energy light than [Ni(H<sub>2</sub>O)<sub>6</sub>]<sup>2+</sup>. Being green, [Ni(H<sub>2</sub>O)<sub>6</sub>]<sup>2+</sup> is probably absorbing red light while violet, [Ni(NH<sub>3</sub>)<sub>6</sub>]<sup>2+</sup> is probably absorbing higher energy yellow-green light.]

22. Which of the following metal ions cannot form both highspin and low-spin octahedral complexes?

(a)  $Ti^{3+}$ 

(b)  $Co_{2+}^{2+}$ 

(c)  $Fe^{2+}$ 

(d) Cu<sup>2+</sup>

[Ans. (a) and (d)]

23. Rank the following complex ions in order of increasing  $\Delta$ :  $[Cr(NH_3)_6]^{3+}, [Cr(H_2O)_6]^{3+}, [Cr(NO_2)_6]^{3-}.$ 

[Ans.  $[Cr(H_2O)_6]^{3+} < [Cr(NH_3)_6]^{3+} < [Cr(NO_2)_6]^{3-}$ .]

**24.** The value of  $\Delta$  for  $[RhCl_6]^{3-}$  is 243 kJ mol<sup>-1</sup>. What wavelength of light will promote an electron from the  $t_{2g}$  set to the  $e_g$  set? What is the colour of the complex?

[Hint:  $\Delta = hv = h$ .  $\frac{c}{\lambda}$  for one electron

or 
$$\lambda = \frac{h \cdot c}{\Delta} = \frac{6.63 \times 10^{-34} \text{Js} \times 3 \times 10^8 \text{ms}^{-1} \times 6.02 \times 10^{23}}{243 \times 10^3 \text{J}}$$
  
= 492 × 10<sup>-9</sup> m = 492 nm, orange]

### INTEGER ANSWER Type Questions

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. How many number of unpaired electrons are present in  $d^6$ , low spin octahedral complex?
- 2. On treatment of 100 mL of 0.1 *M* solution of the complex CoCl<sub>3</sub>·6NH<sub>3</sub> with excess of AgNO<sub>3</sub>, 4.305 g of AgCl was obtained. What is the positive charge present on the complex ion?
- 3. The possible number of geometrical isomers for the complex  $[Pt(NH_3)(NH_2OH)(NO_2)(py)]NO_2$  are:

- **4.** The oxidation number of M in the compound  $[M(NH_3)_5SO_4]$  is:
- 5. A certain complex ion has the formula  $[M(en)_2Br_2]^+$  where M is the metal ion and en = ethylene diamine. How many isomers are possible for this?
- 6. What is the value of spin only magnetic moment value of  $Cr(CO)_6$ ?
- 7. How many unpaired electrons are present in  $[Fe(H_2O)_5NO]SO_4$  complex?
- **8.** How many H-bonds are present in the complex entity formed for Ni<sup>2+</sup> and dimethylglyoxime?

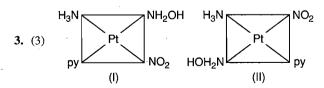

### Answers

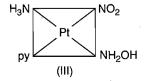

1. (0) Octahedral complex has  $d^2sp^3$  hybridisation.

2. (3) Number of moles of complex =  $\frac{0.1}{1000} \times 100 = 0.01$  mole

Number of moles of AgNO<sub>3</sub> =  $\frac{4.305}{143.5}$  = 0.03 mole

This shows that three chloride ions are present in the complex. The formula is  $[Co(NH_3)_6]Cl_3$ .

- 4. (2)
- 5. (3) Geometrical isomers, cis form has optical isomer.
- **6.** (0) In  $Cr(CO)_6$ , there is no unpaired electron.
- 7. (3) The oxidation state of Fe in the complex is +1. Thus Fe<sup>+</sup> has configuration  $3d^7$ . Thus, there are three unpaired electrons.

8. (2) 
$$CH_3 - C = N$$
  $N = C - CH_3$   $CH_3 - C = N$   $N = C - CH_3$   $N = C - CH_3$ 

- 53. What is the crystal field splitting energy or crystal field stabilisation energy (CFSE) for d' configuration for strong ligand field?
  - (a)  $-1.6 \Delta_0$
- (b)  $-2.0 \Delta_0$
- (c)  $-2.4 \Delta_0$
- (d)  $-1.8 \Delta_0$
- 54. In the following complexes of manganese what is the distribution of electrons on d-orbitals of manganese?
  - (i)  $[Mn(H_2O)_6]^{2+}$
- (ii) [Mn(CN)<sub>6</sub>]<sup>4</sup>
- (a)  $t_{2g}^3 e_g^2$  in both
- (b)  $t_{2g}^5 e_g^0$  in both
- (c)  $t_{2g}^3 e_g^2$  in (i) and  $t_{2g}^5 e_g^0$  in (ii)
- (d)  $t_{2g}^5 e_g^0$  in (i) and  $t_{2g}^3 e_g^2$  in (ii)

#### Passage 2

The d-block elements include the most common metal used in construction and manufacturing, metals that are valued for their beauty, metals used in coins and metals used in modern technology. The d-block elements include the densest elements, the metals with the highest melting and lowest melting points. Some of the members are radioactive and certain d-block elements are particularly important in living organisms. A number of compounds of d-block elements are used for special purposes.

- 55. Which of the element possesses the highest melting point?
  - (a) La

(b) W

(c) S

- (d) Pt
- **56.** Which of the element possesses highest density?

(b) Ag

(c) Au

- (d) Ir
- **57.** How many d-block elements are radioactive in nature?

(b) 9

(c) 10

- (d) 11
- 58. Wilkinson's catalyst is a transition metal complex in which the metal is:
  - (a) Rh

(b) Ru

(c) Fe

(d) Ni

### iswers with Hints

1. (a) The magnetic moment depends on the number of unpaired electrons.

> Mag. moment =  $\sqrt{n(n+2)}$  where n is the number of unpaired electrons.

 $Ti^{3+}$ 

→ Minimum mag. moment

Ni<sup>2+</sup>  $3d^7$ 

Co<sup>2+</sup>

 $Mn^{2+}$ 

- 2. (b)
- 3.
  - (d) (c)  $[Fe(CN)_6]^{4-}$  $Fe^{2+}3d^{6}$  $d^2sp^3$  octahedral diamagnetic

 $[Ni(CN)_4]^{2+}$  $Ni^{2+}3d^{8}$ 

Ni(CO)<sub>4</sub>

diamagnetic

 $Ni^{6}3d^{10}$ sp3 tetrahedral diamagnetic

- (a) Cu<sup>+</sup> is colourless as it contains completely filled d-orbitals.
- (c)  $2CrO_A^{2-} + 2H^+ \rightarrow Cr_2O_7^{2-} + H_2O$
- 7. (b)  $Cu^{2+} + 2CN^{-} \longrightarrow Cu(CN)_2 \longrightarrow Cu_2(CN)_2$  $Cu_2(CN)_2 + 6KCN \longrightarrow 2K_3[Cu(CN)_4]$ i.e.,  $[Cu(CN)_4]^{3-}$  is formed in which Cu(I) is present which is colourless.
- 8. (c) Only primary valencies are ionised.

$$\begin{split} [\text{Co(NH}_3)_5\text{Cl}]\text{Cl}_2 & \longleftarrow \underbrace{[\text{Co(NH}_3)_5\text{Cl}]^{2^+} + 2\text{Cl}^-}_{3 \text{ ions}} \\ & \xrightarrow{-2\text{AgNO}_3} 2\text{AgCl} + [\text{Co(NH}_3)_5\text{Cl}](\text{NO}_3)_2 \end{split}$$

(a) The oxides with lower oxidation states are basic while with higher oxidation states are acidic.

> The oxides with intermediate states are amphoteric. CrO and V2O3 are basic in nature. Mn2O7 is an acidic oxide. Cr<sub>2</sub>O<sub>3</sub> shows amphoteric nature.

**10.** (b) Cis-[Co(en)(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>]<sup>+</sup> exists in optically active forms.

$$\begin{bmatrix} Cl \\ Cl \\ NH_3 \end{bmatrix}^+ \begin{bmatrix} Cl \\ Cl \\ H_3N \end{bmatrix}$$

$$NH_3$$

11. (a) Magnetic moment depends on the number of unpaired electrons.

$$Cr^{3+}$$
  $\uparrow \uparrow \uparrow \uparrow \uparrow \stackrel{\times}{\searrow} \stackrel{\times}{\times}$ 

One unpaired electron

 $\times$   $\times$   $\times$   $\times$  No unpaired electron ↑↓ × ×

 $3d^{10} sp^3d^2$ 

No unpaired electron

12. (c) Higher the oxidation state of the metal greater is the crystal field splitting. The species (c) is in the +3 oxidation state while others are in +2 state.

- 34. (A) KCN gives K<sub>3</sub>[Cu(CN)<sub>4</sub>] complex compound with CuSO<sub>4</sub>
  - (R) KCN reduces Cu<sup>2+</sup> to Cu<sup>+</sup> and then forms a complex
- 35. (A) Silver is recovered from argentocyanide complex by adding zinc dust.
  - (R) Zinc is less electropositive than silver.
- 36. (A) Scandium and zinc are two members of first transition series which do not form coloured compounds.
  - (R) Scandium compounds have  $3d^0$  configuration while zinc compounds have  $3d^{10}$  configuration, i.e., there is no d-d
- 37. (A) The highest oxidation state of manganese is +6.
  - (R) The highest oxide formed by manganese is acidic in
- 38. (A)  $[Fe(CN)_6]^{3-}$  is weakly paramagnetic while  $[Fe(CN)_6]^{4-}$  is diamagnetic.
  - (R) Both  $[Fe(CN)_6]^3$  and  $[Fe(CN)_6]^4$  involve  $d^2sp^3$ hybridisation. In rearranging electrons in d-orbitals, one d-orbital is singly occupied in [Fe(CN)<sub>6</sub>]<sup>3-</sup> and all d-orbitals are doubly occupied in  $[Fe(CN)_6]^4$ .
- 39. (A) The order of increasing crystal field splitting in the three complexes of iron is:

 $[FeCl_6]^{4-} < [Fe(H_2O)_6]^{2+} < [Fe(H_2O)_6]^{3+}$ 

- (R) The crystal field splitting depends on the position of ligand in the spectrochemical series and oxidation state of central metal ion.
- **40.** (A)  $[Cr(H_2O)_2(C_2O_4)_2]^-$  shows geometrical isomerism.
  - (R) [Co(NH<sub>3</sub>)<sub>5</sub>(NO<sub>2</sub>)] (NO<sub>3</sub>)<sub>2</sub> shows ionisation and linkage isomerism.

#### MATRIX MATCHING QUESTIONS

41. Match Column-II with Column-II:

#### Column-I

#### Column-II

- (a) Mercury
- (m) d-block element
- (b) Lanthanum
- (n) f-block element
- (c) Uranium
- (o) Radioactive element
- (d) Technetium
- (e) Americium
- (p) Synthetic element
- (q) Variable valency
- 42. Match Column-II with Column-II:

#### Column-I

#### Column-II

- (a)  $K_2MnO_4$
- (p) Transition element in +6 oxidation state
- (b) KMnO<sub>4</sub>
- (q) Oxidising agent in acid medium
- (c) K<sub>2</sub>CrO<sub>4</sub>
- (r) Obtained from pyrolusite ore
- (d)  $K_2Cr_2O_7$
- (s) Obtained from chromite ore
- 43. Match Column-I with Column-II:

#### Column-I

#### Column-II

- (a)  $[Fe(CN)_6]^4$
- (q) Diamagnetic
- (b)  $[Cu(NH_3)_4]^{2+}$ (c)  $[Mn(CN)_6]^2$
- (r) Unpaired electron or electrons

(p) Paramagnetic

- (d)  $[CuCl_4]^{2-}$
- (s)  $sp^3$ -hybridisation
- (e)  $[Fe(CN)_6]^{3}$
- (t)  $d^2sp^3$ -hybridisation
- 44. Match Column-I with Column-II:

#### Column-I

#### Column-II

- (a) [Co(en)<sub>2</sub>Cl<sub>2</sub>]Cl
- (p) Linkage isomerism
- (b) [Co(NH<sub>3</sub>)<sub>3</sub>Cl<sub>3</sub>]
- (q) Optical isomerism
- (c) [Cr(NH<sub>3</sub>)<sub>5</sub>NO<sub>2</sub>]Cl<sub>2</sub>
- (r) Geometrical isomerism
- (d)  $[Co(en)_3]Cl_3$
- (s) Ionisation isomerism

#### INTEGER ANSWER TYPE

- 45. The effective atomic number (EAN) of a metal carbonyl,  $M(CO)_x$  is 36. The atomic number of M is 26. The value of x
- 46. A weak field complex of Ni<sup>2+</sup> has magnetic moment value of 2.82 BM. The number of electrons in the  $t_{2g}$  level of Ni<sup>2+</sup> will
- 47. The number of unpaired electrons present in chromium atom
- 48. The number of NaCl molecules in the following balanced equation is:

$$K_2Cr_2O_7 + H_2SO_4 + NaCl \longrightarrow KHSO_4 + NaHSO_4 + CrO_2Cl_2 + H_2O$$

- 49. In hydrated ferric chloride, how many water molecules are coordinated to iron ion?
- 50. What is the oxidation state of the central metal atom in [Fe(EDTA)] complex ion?

#### LINKED COMPREHENSION TYPE

#### Passage 1

In octahedral complexes with six ligands surrounding the metal atom/ion, the degeneracy of d-orbitals is disturbed due to repulsions between the ligands and d-orbitals. The repulsions between  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals and the ligands are greater than  $d_{xy}$ ,  $d_{yz}$  and  $d_{zx}$  orbitals and ligands. Thus, there is splitting of d-orbitals into two sets, i.e., two orbitals of higher energy,  $e_e$  set and three orbitals of lower energy,  $t_{2g}$  set. The difference of energy between the two sets of d-orbitals is called crystal field splitting energy and is represented by  $\Delta_0$ . For any given metal cation, the magnitude of  $\Delta_0$  depends upon the nature of the ligands. Some ligands produce strong fields and hence splitting is large whereas some others produce weak fields and hence they result in small splitting of *d*-orbitals.

- **51.** In an octahedral crystal field,  $e_g$ , orbitals are:
  - (a) raised in energy by  $0.4 \Delta_0$
  - (b) lowered in energy by  $0.6 \Delta_0$
  - (c) raised in energy by  $0.6 \Delta_0$
  - (d) lowered in energy by  $0.4 \Delta_0$
- **52.** Predict the order of  $\Delta_0$  for the following complexes:
  - (A)  $[Fe(H_2O)_6]^{2+}$ , (B)  $[Fe(CN)_4(H_2O)_2]^{2-}$ , (C)  $[Fe(CN)_6]^4$
  - (a) (A) < (B) < (C)
- (b) (B) < (C) < (A)
- (c) (C) < (B) < (A)
- (d) (B) < (A) < (C)

	(c) $[PtCl(dien)]Cl, [NiCl_2Br_2]^2$		(c) La is an element of transition series rather than lanthanoid
	(d) $[Co(NO_3)_3(NH_3)_3]$ , $Cis$ - $[Pt(en)_2Cl_2]$		series.
20.	For which of the following species d-d transition does not		(d) Atomic radius of Zr and Hf is same due to lanthanoid
	account for its colour?	27	contraction.
	(a) $Cr_2O_7^{2-}$	27.	Which of the following is not correct for $[Cr(NH_3)_6]Cl_3$ ?  (a) It gives white precipitate with AgNO <sub>3</sub> .
	(c) $CrO_2Cl_2$ $\Box$ (d) All of these $\Box$	•	(a) It gives white precipitate with AgNO <sub>3</sub> .
21.	Mn <sup>2+</sup> forms a complex with Br <sup>-</sup> ion. The magnetic moment		(c) It is dramagnetic.
	of the complex is 5.92 BM. The probable formula and		(d) It is colourless.
	geometry of the complex is:	28.	Identify the false statements.
	(a) $[MnBr_4]^{2-}$ ; tetrahedral		(a) The hybridisation of Cr in $[Cr(H_2O)_6]Cl_3$ is $d^2sp^3$ .

# CHAPTER 16

# Stoichiometry

(Calculations Based on Chemical Equations)

#### Contents:

- 16.1 Introduction
- 16.2 Calculations Involving Mass-Mass Relationship
- 16.3 Calculations Involving Mass-Volume Relationship
- 16.4 Calculations Involving Volume-Volume Relationship

#### 16.1 INTRODUCTION

A chemical equation\* is a short-hand method of depicting a chemical change with the help of chemical symbols and formulae and it relates both the qualitative and quantitative aspects of a chemical change. As a symbol or a formula has a quantitative meaning, in the same fashion, an equation formed with them also gives quantitative information relating the ingredients (reacting materials) and the products of the reaction.

Calculations based on chemical equations are known as **stoichiometric** calculations. Calculations based on chemical equations are of three types:

- (i) Calculations involving mass-mass relationship.
- (ii) Calculations involving mass-volume relationship.
- (iii) Calculations involving volume-volume relationship.

# 16.2 CALCULATIONS INVOLVING MASS-MASS RELATIONSHIP

In general, the following steps are adopted in making necessary calculations:

- (i) Write down balanced molecular equation of the chemical change.
- (ii) Write down the number of moles below the formula of each of the reactants and products.
- (iii) Write down the relative masses of the reactants and products with the help of formula below the respective formula. These shall be theoretical amounts of reactants and products.
- (iv) By the application of unitary method or the rule of three, the unknown factor is determined.

<sup>\*</sup>For details, consult Chapter 1, Physical Chemistry for Competitions.

**Problem 1.** How many grams of oxygen are required to burn completely 570 g of octane?

#### **Solution:**

Balanced equation of the chemical change is:

$$2C_8H_{18} + 25O_2 \longrightarrow 16CO_2 + 18H_2O$$
2 mole 25 mole 2 × 114 25 × 32

For burning  $2 \times 114$  g of octane, oxygen required

$$= 25 \times 32 \text{ g}$$

For burning 1 g of octane, oxygen required

$$=\frac{25\times32}{2\times114}\,\mathrm{g}$$

Thus, for burning 570 g of octane, oxygen required

$$=\frac{25\times32}{2\times114}\times570$$

**Problem 2.** Calculate the number of grams of magnesium chloride that could be obtained from 17.0 g of HCl when HCl is reacted with excess of magnesium oxide.

#### **Solution:**

Balanced equation of the chemical change is:

MgO + 2HCl 
$$\longrightarrow$$
 MgCl<sub>2</sub> + H<sub>2</sub>O  
1 mole 2 mole 1 mole 1 mole 2 × 36.5 g (24 + 71) g 95 g  
73 g of HCl produce MgCl<sub>2</sub> = 95 g  
1 g of HCl produce MgCl<sub>2</sub> =  $\frac{95}{73}$  g 95

17 g of HCl will produce 
$$MgCl_2 = \frac{95}{73} \times 17$$
 g = 22.12 g

**Problem 3.** The amount of carbon monoxide in a gas sample can be determined by using the reaction,

$$I_2O_5 + 5CO \longrightarrow I_2 + 5CO_2$$

If a gas sample liberates 0.384 g of  $I_2$ , how many grams of CO were present in the sample?

#### Solution:

$$I_2O_5 + 5CO \longrightarrow I_2 + 5CO_2$$
 $\begin{array}{ccc}
5 & \text{mole} & & 1 & \text{mole} \\
5 \times 28.0 & & & 253.8 & g
\end{array}$ 

253.8 g of iodine liberated when CO is present in the sample =  $5 \times 28$  g

1 g of iodine liberated when CO is present in the sample

$$=\frac{5\times28}{253.8}$$
 §

0.384 g of iodine liberated when CO is present in the sample

$$= \frac{5 \times 28}{253.8} \times 0.384 = 0.212 \text{ g}$$

**Problem 4.** Calculate the weight of iron which will be converted into its oxide by the action of 18 g of steam.

[M.L.N.R. 1996]

#### **Solution:**

The balanced equation for the chemical change is:

$$3Fe + 4H2O \longrightarrow Fe3O4 + 4H2$$
3 mole 4 mole
3 × 56 g 4 × 18 g
$$4 \times 18 \text{ g of steam convert iron into } Fe3O4 = 3 \times 56 \text{ g}$$

1 g of steam converts iron into 
$$Fe_3O_4 = \frac{3 \times 56}{4 \times 18}$$
 g

18 g of steam convert iron into 
$$Fe_3O_4 = \frac{3 \times 56}{4 \times 18} \times 18$$
 g = 42 g

**Problem 5.** Calculate the residue obtained on strongly heating 2.76 g  $Ag_2CO_3$ .

#### **Solution:**

The balanced equation for the chemical change is:

$$Ag_2CO_3 \xrightarrow{\text{Heat}} 2Ag + CO_2 + \frac{1}{2}O_2$$
1 mole 2 mole
276 g 2 × 108 g

f Ag\_2CO\_2 give silver on heating = 2

276 g of 
$$Ag_2CO_3$$
 give silver on heating = 216 g

2.76 g of Ag<sub>2</sub>CO<sub>3</sub> give silver on heating = 
$$\frac{216}{276} \times 2.76$$
 g = 2.16 g

#### Limiting Reagent

In general, when a chemical reaction is carried out, one of the reagents will be used in excess of the amount required. The reagent that is not present in excess is the one that will determine how much product can be obtained and is thus referred to as the limiting reagent. The reagent that gives the least number of moles of the product is the limiting reagent.

With the help of limiting reagent, the amount of the excess reagent which has been utilised and the amount remaining can be calculated. This can be clearly understood from the following problems:

**Problem 6.** 100 g sample of calcium carbonate is reacted with 70 g of orthophosphoric acid. Calculate:

- (a) the number of grams of calcium phosphate that could be produced.
- (b) the number of grams of excess reagent that will remain unreacted.

#### **Solution:**

The balanced equation is:

100 g of CaCO<sub>3</sub> would produce 
$$Ca_3(PO_4)_2 = \frac{310}{300} \times 100$$
  
= 103 g  
= 0.33 mole

196 g of 
$$H_3PO_4$$
 produce  $Ca_3(PO_4)_2 = 310$  g or 1 mole  
70 g of  $H_3PO_4$  would produce  $Ca_3(PO_4)_2 = \frac{310}{196} \times 70$   
= 110.7 g  
= 0.356 mole

The above values tell that CaCO<sub>3</sub> is the limiting reagent. Hence, calcium phosphate formed is 0.33 mole or 103 g. For producing 103 g of Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>, H<sub>3</sub>PO<sub>4</sub> required will be

$$=\frac{196}{310} \times 103 = 65.12 \text{ g}$$

Mass of remaining orthophosphoric acid = (70 - 65.12)= 4.88 g

**Problem 7.** What is the maximum mass of  $Al(OH)_3$  that can be prepared by reaction of 13.4 grams of  $AlCl_3$  with 10 grams of NaOH according to the following equation?

$$AlCl_3 + 3NaOH \longrightarrow Al(OH)_3 + 3NaCl$$

#### Solution:

The balanced equation is:

$$AlCl_3 + 3NaOH \longrightarrow Al(OH)_3 + 3NaCl$$
1 mole 3 mole 1 mole
133.5 g 120 g 78.0 g

133.5 g of AlCl<sub>3</sub> produce Al(OH)<sub>3</sub> = 78.0 g

13.4 g of AlCl<sub>3</sub> produce Al(OH)<sub>3</sub> = 
$$\frac{78.0}{133.5}$$
 × 13.4 = 7.829 g

120 g of NaOH produce  $Al(OH)_3 = 78 g$ 

10 g of NaOH produce Al(OH)<sub>3</sub> = 
$$\frac{78}{120}$$
 × 10 = 6.5 g

Hence, NaOH is a limiting reagent. Thus,  $Al(OH)_3$  produced in the reaction is 6.5 g.

**Problem 8.** 200 grams of marble chips are dropped into 100 g of hydrochloric acid. How much chips will remain undissolved? What weight of anhydrous calcium chloride and what weight of carbon dioxide gas could be obtained from it?

#### **Solution:**

The balanced equation for the chemical change is:

Since marble chips remain undissolved, HCl is a limiting reagent.

73 g of HCl react with 
$$CaCO_3 = 100 \text{ g}$$

100 g of HCl will react with 
$$CaCO_3 = \frac{100}{73} \times 100$$

Weight of chips undissolved = 200-136.986= 63.014g

73 g of HCl produce  $CaCl_2 = 111$  g

100 g of HCl will produce 
$$CaCl_2 = \frac{111}{73} \times 100 = 152.05 \text{ g}$$

73 g of HCl produce 
$$CO_2 = 44$$
 g

100 g of HCl will produce 
$$CO_2 = \frac{44}{73} \times 100 = 60.27$$
 g

#### Calculations Involving Per cent Yield

In general, when a reaction is carried out in the laboratory we do not obtain actually the theoretical yield of the product. The amount of the product that is actually obtained is called the actual yield. Knowing the actual yield and theoretical yield, the per cent yield can be calculated by the following formula:

Per cent yield = 
$$\frac{\text{Actual yield}}{\text{Theoretical yield}} \times 100$$

**Problem 9.** A 7.8 g sample of  $C_6H_6$  reacts with excess of  $HNO_3$  to produce 9.0 g of  $C_6H_5NO_2$ . What is the per cent yield of  $C_6H_5NO_2$  in this experiment?

#### Solution:

The balanced equation is:

$$\begin{array}{cccc} C_6H_6 \ + \ HNO_3 \longrightarrow & C_6H_5NO_2 \ + \ H_2O \\ \hline 1 \ mole & 1 \ mole & 1 \ mole \\ \hline 78 \ g & 123 \ g \end{array}$$

78 g of benzene produce  $C_6H_5NO_2 = 123 \text{ g}$ 

7.8 g of benzene will produce 
$$C_6H_5NO_2 = \frac{123}{78} \times 7.8$$
  
= 12.3 g

i.e., theoretical yield of 
$$C_6H_5NO_2 = 12.3 g$$

Actual yield = 
$$9.0 g$$

Per cent yield = 
$$\frac{\text{Actual yield}}{\text{Theoretical yield}} \times 100$$
  
=  $\frac{9.0}{12.3} \times 100 = 73.17$ 

**Problem 10.** If  $4.80 \text{ g of } N_2F_4$  is obtained when 4.00 g of  $NH_3$  is reacted with  $14.0 \text{ g of } F_2$  according to the following reaction,

$$2NH_3 + 5F_2 \longrightarrow N_2F_4 + 6HF$$

what is the per cent yield?

#### **Solution:**

The balanced equation is:

34 g of NH<sub>3</sub> react with fluorine = 190 g

4 g of NH<sub>3</sub> react with fluorine = 
$$\frac{190}{34} \times 4$$
  
= 22.35 g

This shows that fluorine is a limiting reagent.

190.0 g of fluorine produce 
$$N_2F_4 = 104.0$$
 g

14.0 g of fluorine produce 
$$N_2F_4 = \frac{104.0}{190.0} \times 14.0$$
  
= 7.66 g

*i.e.*, theoretical yield = 
$$7.66 \text{ g}$$

Actual yield = 4.80 g  
Per cent Yield = 
$$\frac{\text{Actual yield}}{\text{Theoretical yield}} \times 100$$
  
=  $\frac{4.80}{7.66} \times 100 = 62.66$ 

#### Successive Reactions

In such reactions, the products of one reaction are used up in one or more subsequent reactions. For solving these problems, balanced and molecular equations are written for all reactions involved separately. The individual equations are multiplied as a whole by suitable factors in order to cancel out the products of one reaction which are utilized in the subsequent reactions. The unknown factors are now equated with the known factors and their values are thus determined.

**Problem 11.** Find out the weight of calcium carbonate that must be decomposed to produce sufficient quantity of carbon dioxide to convert 10.6 g of sodium carbonate completely into sodium bicarbonate.

#### Solution:

The balanced equations are:

1 mole 1 mole 100 g 44 g

106 g Na<sub>2</sub>CO<sub>3</sub> are completely converted into NaHCO<sub>3</sub> by 44 g of CO<sub>2</sub>.

10.6 g Na<sub>2</sub>CO<sub>3</sub> are completely converted into NaHCO<sub>3</sub> by CO<sub>2</sub>

$$=\frac{44}{106}\times10.6=4.4$$
 g

From equation (ii), it is clear that,

44 g of  $CO_2$  is obtained from  $CaCO_3 = 100$  g

4.4 g of CO<sub>2</sub> is obtained from 
$$CaCO_3 = \frac{100}{44} \times 4.4 = 10$$
 g

Problem 12. From the following reaction sequence,

$$Cl_2 + 2KOH \longrightarrow KCl + KClO + H_2O$$
  
 $3KClO \longrightarrow 2KCl + KClO_3$   
 $4KClO_3 \longrightarrow KCl + 3KClO_4$ 

calculate the mass of chlorine needed to produce 50 g of  $KClO_4$ .

#### **Solution:**

The given balanced equations are:

$$[Cl_2 + 2KOH \longrightarrow KCl + KClO + H_2O] \times 12$$

$$[3KClO \longrightarrow 2KCl + KClO_3] \times 4$$

$$4KClO_3 \longrightarrow KCl + 3KClO_4$$

Adding 
$$12\text{Cl}_2 + 24\text{KOH} \longrightarrow 21\text{KCl} + 3\text{KClO}_4 + 12\text{H}_2\text{O}$$
  
 $12 \text{ mole}$  3 mole  
 $12 \times 71 \text{ g}$  3 × 138.5 g

 $3 \times 138.5$  g of KClO<sub>4</sub> are obtained by the use of chlorine =  $12 \times 71$  g

50 g of KClO<sub>4</sub> will be obtained by the use of chlorine

$$= \frac{12 \times 71}{3 \times 138.5} \times 50$$
$$= 102.527 \text{ g}$$

**Problem 13.** 1 gram of pyrolusite was boiled with excess of concentrated HCl and the issuing gas was passed through a solution of potassium iodide when 1.27 g of iodine were liberated. What was the percentage of pure  $MnO_2$  in the pyrolusite sample? [Mn = 55; Cl = 35.5; K = 39; I = 127]

#### **Solution:**

The following equations are involved in the problem:

$$2KI + Cl_2 \longrightarrow 2KCl + I_2$$

$$MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$$

Adding 
$$MnO_2 + 4HCl + 2KI \rightarrow MnCl_2 + 2KCl + 2H_2O + I_2$$
  
1 mole 1 mole  $87 \text{ g}$   $2 \times 127 \text{ g}$ 

 $2 \times 127$  g of  $I_2$  are obtained from manganese dioxide

1.27 g of I<sub>2</sub> are obtained from manganese dioxide

$$= \frac{87}{2 \times 127} \times 1.27 = 0.435 \text{ g}$$

Percentage of purity of pyrolusite  $=\frac{0.435}{1} \times 100 = 43.5$ 

#### Composition of Mixtures

**Problem 14.** 2.662 grams of a mixture of potassium chloride and sodium chloride gave on treatment with silver nitrate solution, 5.752 grams of dry silver chloride. Find the percentage composition of the mixture.

$$[Na = 23; K = 39.1; Cl = 35.5; Ag = 108]$$

#### **Solution:**

Let x g NaCl be present in the mixture.

The amount of KCl in the mixture = (2.662 - x) g

The reactions which occur in the formation of AgCl are:

(i) NaCl + AgNO<sub>3</sub> 
$$\longrightarrow$$
 AgCl + NaNO<sub>3</sub>

1 mole
1 mole
143.5 g

(ii) 
$$KCl + AgNO_3 \longrightarrow AgCl + KNO_3$$
1 mole 1 mole
74.6 g 143.5 g

$$58.5 \text{ g NaCl give AgCl} = 143.5 \text{ g}$$

x g NaCl give AgCl = 
$$\frac{143.5 \times x}{58.5}$$
 = 2.453x g

$$74.6 \text{ g KCl give AgCl} = 143.5 \text{ g}$$

$$(2.662 - x)$$
 g KCl give AgCl =  $\frac{143.5 \times (2.662 - x)}{74.6}$   
=  $(5.12 - 1.924 \ x)$  g

So, 
$$2.453x + (5.12 - 1.924x) = 5.752$$

or 
$$0.529x = 0.632$$
  
 $x = \frac{0.632}{0.529} = 1.195 \text{ g}$ 

The mixture contains NaCl = 1.195 g

Percentage of NaCl = 
$$\frac{1.195}{2.662} \times 100 = 44.89$$

Percentage of KCl = (100 - 44.89) = 55.11

**Problem 15.** Determine the percentage composition of a mixture of anhydrous sodium carbonate and sodium bicarbonate from the following data:

Mass of the mixture taken = 3.0 g

Loss in mass on heating = 0.186 g

$$[Na = 23; C= 12; O= 16]$$

#### **Solution:**

On heating only sodium bicarbonate will decompose according to the following equation:

Loss = (168 - 106) g = 62 g

62 g loss occur when sodium bicarbonate heated = 168 g 0.186 g loss occur when sodium bicarbonate heated

$$=\frac{168}{62}\times0.186=0.504$$

Percentage of NaHCO<sub>3</sub> = 
$$\frac{0.504}{3.0} \times 100 = 16.8$$

Percentage of anhydrous  $Na_2CO_3 = (100 - 16.8)$ 

= 83.2

**Problem 16.** A mixture of FeO and Fe<sub>3</sub>O<sub>4</sub> when heated in air to constant weight gains 5% in its weight. Find the composition of initial mixture. [Fe = 55.8; O = 16]

#### Solution:

Let the total mass of mixture be = 100 g

Let the mass of FeO be x g and that of Fe<sub>3</sub>O<sub>4</sub> will be (100 - x) g. Both the oxides on heating are converted into Fe<sub>2</sub>O<sub>3</sub> according to following equations:

(i) 
$$2\text{FeO} + \frac{1}{2}\text{O}_2 \longrightarrow \text{Fe}_2\text{O}_3$$
  
143.6 g 159.6 g

(ii) 
$$2\text{Fe}_3\text{O}_4 + \frac{1}{2}\text{O}_2 \longrightarrow 3\text{Fe}_2\text{O}_3$$
  
 $462.8 \text{ g}$   $478.8 \text{ g}$ 

Mass of Fe<sub>2</sub>O<sub>3</sub> produced from x g of FeO =  $\frac{159.6 \times x}{143.6}$  g

Mass of  $Fe_2O_3$  produced from (100 - x) g of  $Fe_3O_4$ 

$$=\frac{478.8}{462.8}\times(100-x)$$
 g

Total mass of  $Fe_2O_3$  produced = 105 g

So, 
$$\frac{159.6 \times x}{143.6} + \frac{478.8}{462.8} (100 - x) = 105$$

On solving

x = 20.78

Hence, the initial composition of the mixture is:

FeO = 20.78% and  $Fe_3O_4 = 79.22\%$ 

# 16.3 CALCULATIONS INVOLVING MASS-VOLUME RELATIONSHIP

These calculations are based on the fact that 1 mole or 1 g molecule of the substance occupies 22.4 litres or 22400 mL at N.T.P. The following example shows the mass-volume relationship:

Volume of a gas at any temperature and pressure can be converted into mass or *vice-versa* with the help of equation,

$$PV = \frac{w}{M}RT$$

where w is the mass of the gas, M is the molecular mass and R is molar gas constant.

**Problem 17.** Calculate the volume of carbon dioxide at N.T.P. evolved by strong heating of 20 g calcium carbonate.

#### **Solution:**

The balanced equation is:

**Problem 18.** Calculate the volume of hydrogen liberated at 27°C and 760 mm pressure by treating 1.2 g of magnesium with excess of hydrochloric acid.

Solution: The balanced equation is:

$$\begin{array}{ccc} Mg + 2HCl & \longrightarrow MgCl_2 + H_2 \\ \text{l mole} & \text{l mole} \\ 24 \text{ g} & \text{22.4 litre} \\ & \text{at N.T.P.} \end{array}$$

24 g of Mg liberate hydrogen = 22.4 litre

1.2 g Mg will liberate hydrogen = 
$$\frac{22.4}{24} \times 1.2$$
  
= 1.12 litre

Volume of hydrogen under given condition can be calculated by applying,

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2}$$

$$P_1 = 760 \text{ mm}$$

$$T_1 = 273 \text{ K}$$

$$V_1 = 1.12 \text{ litre}$$

$$V_2 = \frac{760 \times 1.12}{273} \times \frac{300}{760} = 1.2308 \text{ litre}$$

**Problem 19.** What quantity of copper (II) oxide will react with 2.80 litre of hydrogen at N.T.P.?

#### **Solution:**

The balanced equation is:

$$\begin{array}{ccc} CuO & + & H_2 \longrightarrow Cu + H_2O \\ 1 & mole & 1 & mole \\ 79.5 & g & 22.4 & litre \\ & at & N.T.P. \end{array}$$

22.4 litre of hydrogen at N.T.P. reduce CuO = 79.5 g

2.80 litre of hydrogen at N.T.P. will reduce CuO

$$=\frac{79.5}{22.4} \times 2.80 \text{ g} = 9.94 \text{ g}$$

**Problem 20.** 10 grams of a sample of potassium chlorate gave, on complete decomposition, 2.24 litre of oxygen at N.T.P. What is the percentage purity of the sample of potassium chlorate?

#### Solution:

The balanced equation of the decomposition is:

 $3 \times 22.4$  litre of oxygen obtained from KClO<sub>3</sub> = 245 g

2.24 litre of oxygen obtained from KClO<sub>3</sub> = 
$$\frac{245}{3 \times 22.4} \times 2.24$$
  
= 8.17 g

10 g of sample contains pure  $KClO_3 = 8.17$  g

Percentage purity of the sample = 
$$\frac{8.17}{10} \times 100 = 81.7$$

**Problem 21.** What volume of hydrogen at N.T.P. would be liberated by the action of zinc on 50 mL dilute  $H_2SO_4$  of 40% purity and having specific gravity of 1.3. [Zn = 63.5]

#### Solution:

Mass of 50 mL dilute  $H_2SO_4$  = volume × specific gravity

$$= 50 \times 1.3 = 65 \text{ g}$$

100 g of dilute  $H_2SO_4$  contain = 40 g  $H_2SO_4$ 

65 g of dilute 
$$H_2SO_4$$
 contain  $=\frac{40}{100} \times 65 = 26$  g

The reaction involved is:

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$$
1 mole
1 mole
98 g
22.4 litre
at N.T.P.

At N.T.P. 98 g  $H_2SO_4$  liberate hydrogen with zinc = 22.4 litre

At N.T.P. 26 g H<sub>2</sub>SO<sub>4</sub> will liberate hydrogen with zinc

$$=\frac{22.4}{98} \times 26$$
 litre = 5.94 litre

**Problem 22.** At flash bulb used for taking photograph in poor light contains 30 mL of oxygen at a pressure of 780 mm at 27°C. Supposing that the initial wire flashed is pure magnesium which is oxidised to magnesium oxide in the process of flashing, calculate the minimum mass of magnesium wire that is to be needed for maximum efficiency.

#### **Solution:**

If V is the volume of oxygen at N.T.P., then

$$\frac{760 \times V}{273} = \frac{780 \times 30}{300}$$
$$V = 28 \text{ mL}$$

Mass of 22400 mL of oxygen at N.T.P. = 32 g 32 32 32

Mass of 28 mL of oxygen at N.T.P. = 
$$\frac{32}{22400} \times 28 = 0.04$$
 g

The reaction involved is:

$$\begin{array}{cccc}
2\text{Mg} & + & \text{O}_2 & \longrightarrow 2\text{MgO} \\
2 \times 2^4 & \text{g} & & 32 & \text{g}
\end{array}$$

32 g oxygen oxidise magnesium =  $2 \times 24$  g

0.04 g oxygen oxidise magnesium =  $\frac{2 \times 24}{32} \times 0.04 = 0.06$  g

# 16.4 CALCULATIONS INVOLVING VOLUME-VOLUME RELATIONSHIP

These calculations are based on two laws:

(i) Avogadro's law and (ii) Gay-Lussac's law. For example,

$$2NO$$
 +  $O_2$  =  $2NO_2$  (Avogadro's law)  
 $2 \text{ mole}$  1 mole 2 mole  
 $2 \times 22.4 \text{ litre}$  22.4 litre 2 × 22.4 litre

(Under similar conditions of temperature and pressure, equal moles of gases occupy equal volumes.)

or 
$$2NO + O_2 = 2NO_2$$
 (Gay-Lussac's law)  
2 vol 2 vol

(Under similar conditions, gases react in simple ratio of their volumes.)

**Problem 23.** What volume of oxygen gas at N.T.P. is necessary for complete combustion of 20 litre of propane measured at 27°C and 760 mm pressure?

#### **Solution:**

The balanced equation is:

$$C_3H_8 + 5O_2 = 3CO_2 + 4H_2O$$
1 vol 5 vol
1 litre 5 litre

1 litre of propane required = 5 litre of oxygen

20 litre of propane will require =  $5 \times 20$ 

= 100 litre of oxygen at 760 mm and 27°C.

This volume will be converted to N.T.P. conditions. Given conditions,

$$P_1 = 760 \text{ mm}$$
  $P_2 = 760 \text{ mm}$   
 $T_1 = (27 + 273)\text{K} = 300 \text{ K}$   $T_2 = 273 \text{ K}$   
 $V_1 = 100 \text{ litre}$   $V_2 = ?$   
 $V_2 = \frac{760 \times 100}{300} \times \frac{273}{760} \text{ litre}$   
 $V_3 = 91.0 \text{ litre}$ 

**Problem 24.** One litre of a mixture of carbon monoxide and carbon dioxide is passed through a tube containing red hot charcoal. The volume now becomes 1.6 litre. Volumes are measured under similar conditions. Find the composition of gaseous mixture.

#### **Solution:**

When the mixture is passed over red hot charcoal, carbon dioxide present in the mixture is reduced to carbon monoxide. Thus, increase in volume is due to formation of CO from CO<sub>2</sub>.

The desired equation is: 
$$CO_2 + C = 2CO$$

Let x litre of  $CO_2$  be present in the mixture, the volume of carbon monoxide in the mixture = (1 - x) lit. x volume of CO<sub>2</sub> produce 2x volume of CO.

Total volume of CO = 
$$2x + 1 - x = 1 + x$$
  
= 1.6 litre (given)

So.

x = 0.6 litre

Volume of  $CO_2$  in the mixture = 0.6 litre

Volume of CO in the mixture = (1 - 0.6) = 0.4 litre

Problem 25. 1 litre of oxygen at N.T.P. is allowed to react with three times of carbon monoxide at N.T.P. Calculate the volume of each gas found after the reaction.

**Solution:** The desired equation is:

$$\begin{array}{cccc}
2CO & + & O_2 = 2CO_2 \\
2 & \text{vol} & 1 & \text{vol} & 2 & \text{vol}
\end{array}$$

1 vol of O2 reacts with 2 vol of CO

1 litre of O<sub>2</sub> reacts with 2 litre of CO

Thus,

1 litre of CO remains unreacted.

1 vol of  $O_2$  produces  $CO_2 = 2$  vol

or

1 litre of  $O_2$  will produce  $CO_2 = 2$  litre

Thus, gaseous mixture after the reaction consists,

Volume of 
$$CO = 1$$
 litre

Volume of  $CO_2 = 2$  litre

**Problem 26.** The percentage by volume of  $C_3H_8$  in a mixture of C<sub>3</sub>H<sub>8</sub>, CH<sub>4</sub> and CO is 36.5. Calculate the volume of CO<sub>2</sub> produced when 100 mL of the mixture is burnt in excess of  $O_2$ .

#### **Solution:**

The desired balanced equations are:

$$C_{3}H_{8} + 5O_{2} \longrightarrow 3CO_{2} + 4H_{2}O$$

$$1 \text{ vol} \qquad \qquad 3 \text{ vol}$$

$$CH_{4} + 2O_{2} \longrightarrow CO_{2} + 2H_{2}O$$

$$1 \text{ vol} \qquad \qquad 1 \text{ vol}$$

$$CO + \frac{1}{2}O_{2} \longrightarrow CO_{2}$$

$$1 \text{ vol} \qquad \qquad 1 \text{ vol}$$

Let a mL of C<sub>3</sub>H<sub>8</sub>, b mL of CH<sub>4</sub> and c mL of CO be present in 100 mL of mixture, then

$$a+b+c=100$$

Given

$$a = 36.5 \text{ mL}$$

So, 
$$b + c = (100 - 36.5) = 63.5 \text{ mL}$$

Volume of CO<sub>2</sub> formed = 
$$(3a + b + c)$$
  
=  $(3 \times 36.5 + 63.5)$  mL  
=  $109.5 + 63.5 = 173.0$  mL

Problem 27. The weight of one litre of ozonised oxygen at N.T.P. was found to be 1.5 g. When 100 mL of this mixture at N.T.P. were treated with turpentine oil, the volume was reduced to 90 mL. Hence, calculate the molecular mass of [M.L.N.R. 1996] ozone.

#### **Solution:**

Ozone is absorbed by turpentine oil.100 mL of ozonised

mixture is reduced to 90 mL with turpentine oil, i.e., 10 mL of ozone is present in 100 mL of the mixture.

1 L of mixture consists ozone = 100 mL

1 L of mixture consists oxygen = 900 mL

Let the molecular mass of ozone be M.

Mass of 100 mL of ozone = 
$$\frac{M}{22400} \times 100 = \frac{M}{224} g$$

Mass of 900 mL of oxygen = 
$$\frac{32}{22400} \times 900 = \frac{9}{7}$$
 g

So, 
$$\frac{M}{224} + \frac{9}{7} = 1.5$$

or 
$$M + 288 = 336$$

or 
$$M = 336 - 288 = 48$$

**Problem 28.** A gas mixture of 3 litre of propane  $(C_3H_8)$ and butane  $(C_4H_{10})$  on complete combustion at 25°C produced 10 litre  $CO_2$ . Find out the composition of gas mixture.

[M.L.N.R. 1992]

#### **Solution:**

Let a litre of C<sub>3</sub>H<sub>8</sub> and b litre of C<sub>4</sub>H<sub>10</sub> be present in mixture.

$$a + b = 3 \qquad \dots (i)$$

$$C_{3}H_{8} + 5O_{2} \longrightarrow 3CO_{2} + 4H_{2}O$$

$$1 \text{ vol} \qquad 3 \text{ vol}$$

$$C_{4}H_{10} + \frac{13}{2}O_{2} \longrightarrow 4CO_{2} + 5H_{2}O$$

$$1 \text{ vol} \qquad 4 \text{ vol}$$

$$^{4}$$
 vol  $^{2}$  CO<sub>2</sub> formed by  $^{2}$   $^{4}$   $^{2}$   $^{4}$   $^{2}$   $^{2}$   $^{4}$   $^{2}$   $^$ 

CO<sub>2</sub> formed by 
$$C_4H_{10} = 4b$$
  
  $3a + 4b = 10$  ... (ii)

Solving equations (i) and (ii),

$$a = 2$$
 litre

$$b = 1$$
 litre

### Some Miscellaneous Worked Problems

**Problem 29.** An impure sample of calcium carbonate contains 80% pure calcium carbonate. 25 g of the impure sample reacted with excess of hydrochloric acid. Calculate the volume of carbon dioxide at N.T.P. obtained from this sample.

#### Solution:

100 g of impure calcium carbonate contains

= 80 g pure calcium carbonate

25 g of impure calcium carbonate sample contains

$$=\frac{80}{100}\times25$$

= 20 g pure calcium carbonate

The desired equation is:

$$CaCO_3 + 2HCl = CaCl_2 + CO_2 + H_2O$$
1 mole
100 g
22.4 litre
at N.T.P.

100 g pure CaCO<sub>3</sub> liberate = 22.4 litre CO<sub>2</sub>

20 g pure 
$$CaCO_3$$
 liberate =  $\frac{22.4}{100} \times 20$   
= 4.48 litre  $CO_2$ 

**Problem 30.** A sample of hydrochloric acid contains 20% hydrochloric acid by weight. How much of this acid in grams is required for complete reaction with 50 g of calcium carbonate?

#### Solution:

The desired balanced equation is:

CaCO<sub>3</sub> + 2HCl = CaCl<sub>2</sub> + H<sub>2</sub>O + CO<sub>2</sub>  
<sup>1</sup> mole 2 mole  
<sup>100</sup> g 73 g  
100 g of CaCO<sub>3</sub> require = 73 g HCl  
50 g of CaCO<sub>3</sub> will require = 
$$\frac{73}{100} \times 50$$
  
= 36.5 g HCl

20 g of HCl is present in = 100 g sample 36.5 g of HCl is present in =  $\frac{100}{20} \times 36.5$  g sample = 182.5 g sample

Thus, 182.5 g of HCl sample is required for complete reaction with 50 g of calcium carbonate.

**Problem 31.** A mixture of aluminium and zinc weighing 1.67 g was completely dissolved in acid. 1.69 litre of hydrogen measured at 0°C and 1 atm. pressure was evolved. What was the weight of aluminium in the mixture?

**Solution:** Let the mixture contain aluminium x g.

The mixture contains zinc = (1.67 - x) g

Suppose the mixture is dissolved in H<sub>2</sub>SO<sub>4</sub>.

$$2A1 + 3H_2SO_4 = Al_2(SO_4)_3 + 3H_2 \uparrow$$
  
2 × 27 g 3 × 22.4 litre  
at N.T.P.

 $2 \times 27$  g Al will evolve hydrogen =  $3 \times 22.4$  litre

$$x$$
 g Al will evolve hydrogen =  $\frac{3 \times 22.4}{2 \times 27}x$  litre  
Zn + H<sub>2</sub>SO<sub>4</sub>  $\longrightarrow$  ZnSO<sub>4</sub> + H<sub>2</sub>

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + H_2$$
65 g
22.4 litre
at N.T.P.

65 g of zinc evolve hydrogen = 22.4 litre

So, (1.67 - x) g of zinc will evolve hydrogen

$$=\frac{22.4}{65}(1.67-x)$$
 litre

Thus, 
$$\frac{3 \times 22.4}{2 \times 27} x + \frac{22.4}{65} (1.67 - x) = 1.69$$
or 
$$\frac{67.2}{54} x - \frac{22.4}{65} x = 1.69 - \frac{22.4 \times 1.67}{65}$$

$$x = 1.24$$

Weight of Al in the given mixture = 1.24 g

**Problem 32.** A 1.00 g sample of KClO<sub>3</sub> was heated under such conditions that a part of its decomposed according to the equation

$$(i) 2KClO_3 \longrightarrow 2KCl + 3O_2$$

and the remaining underwent change according to the equation,

(ii) 
$$4KClO_3 \longrightarrow 3KClO_4 + KCl$$

If the amount of oxygen evolved was 146.8 mL at S.T.P., calculate the percentage by weight of KClO<sub>4</sub> in the residue.

#### **Solution:**

67.2 litre of oxygen is evolved from = 245 g KClO<sub>3</sub> 0.1468 litre of oxygen will be evolved from

$$=\frac{245}{67.2}\times0.1468=0.5352$$
 g KClO<sub>3</sub>

Hence, KClO<sub>3</sub> left for (ii) reaction.

$$(1.00 - 0.5352) = 0.4648 \text{ g}$$
  
 $245 \text{ g KClO}_3 \text{ yield KCl} = 149 \text{ g}$   
 $0.5352 \text{ g KClO}_3 \text{ will yield KCl} = \frac{149}{245} \times 0.5352 \text{ g}$   
 $= 0.3254 \text{ g}$ 

Considering equation (ii),

0.4648 g KClO<sub>3</sub> will yield 
$$=\frac{415.5}{490} \times 0.4648$$
  
= 0.3941 g KClO<sub>4</sub>  
490g KClO<sub>3</sub> yield = 74.5 g KCl

$$0.4648 \text{ g KClO}_3 \text{ will yield} = \frac{74.5}{490} \times 0.4648$$
  
= 0.0707 g KCl

Total weight of residue = 
$$0.3254 + 0.3941 + 0.0707$$
  
=  $0.7902$  g  
% KClO<sub>4</sub> =  $\frac{0.3941}{0.7902} \times 100 = 49.8$ 

**Problem 33.** 1 g Mg is burnt in a closed vessel which contains 0.5 g of  $O_2$ .

- (i) Which reactant is left in excess?
- (ii) Find the weight of the excess reactant.

#### Solution:

The desired chemical equation is:

$$2Mg + O_2 \longrightarrow 2MgO$$
48 g of Mg react with oxygen = 32 g

1 g of Mg would react with oxygen = 
$$\frac{32}{48}$$
 = 0.67 g

However, only 0.5 g of O<sub>2</sub> is present. Hence, whole of Mg is not burnt and a part of left unreacted.

32 g of oxygen react with magnesium = 48 g  
0.5 g of oxygen would react with magnesium = 
$$\frac{48}{32}$$
 = 0.5 g  
= 0.75 g

Mass of magnesium left unreacted = (1.0 - 0.75) g = 0.25 g

**Problem 34.** 5 g of K<sub>2</sub>SO<sub>4</sub> were dissolved in 250 mL of solution. How many mL of this solution should be used so that 1.2 g of BaSO<sub>4</sub> may be precipitated from BaCl<sub>2</sub> solution? Solution:

The desired equation is:

233 g of BaSO<sub>4</sub> is obtained from = 174 g of K<sub>2</sub>SO<sub>4</sub>

1.2 g of BaSO<sub>4</sub> will be obtained from = 
$$\frac{174}{233} \times 1.2$$
  
= 0.8961 g of K<sub>2</sub>SO<sub>4</sub>

5 g of K<sub>2</sub>SO<sub>4</sub> is present in 250 mL of solution.

So, 0.8961 g of 
$$K_2SO_4$$
 will be present in  $\frac{250}{5} \times 0.8961$   
= 44.8 mL of solution

**Problem 35.** A 5.0 g mixture of lead nitrate and sodium nitrate was heated below  $600^{\circ}$ C until the mass of the residue was constant. If the loss of mass is 28%, find the mass of each component in the original mixture. [Pb = 207; N = 14; O = 16; Na = 23] [1.1.T. 1990]

#### **Solution:**

Let the mass of  $Pb(NO_3)_2$  in the mixture be x g. The mass of sodium nitrate = (50 - x) g The desired reactions in the problem are :

$$\begin{array}{c} \text{2Pb(NO}_3)_2 \longrightarrow \text{2PbO} + 4\text{NO}_2 + \text{O}_2 \\ \text{662 g} & \text{446 g} \\ \text{2NaNO}_3 \longrightarrow \text{2NaNO}_2 + \text{O}_2 \\ \text{170g} & \text{138g} \end{array}$$

Loss in mass is 28% of 5 g =  $\frac{28}{100} \times 5 = 1.4$  g

Mass of residue left = (5 - 1.4) = 3.6 g ... (i)

662 g lead nitrate produce on heating PbO = 446 g

x g lead nitrate would produce on heating PbO =  $\frac{446}{662} \times x$  g Similarly, 170 g NaNO<sub>3</sub> produce NaNO<sub>2</sub> on heating = 138 g

(5.0 - x) g NaNO<sub>3</sub> produce NaNO<sub>2</sub> on heating =  $\frac{138}{178} \times (5 - x)$ Total residue after heating

/ AAC 120

$$= \frac{446}{662}x + \frac{138}{170} \times (5 - x) \qquad \dots \text{ (ii)}$$

Equating (i) with (ii),

$$\frac{446}{662}x + \frac{138}{170}(5 - x) = 3.6$$

On solving,

$$x = 3.32$$

Mass of lead nitrate in mixture = 
$$3.32 \text{ g}$$
  
Mass of sodium nitrate in mixture =  $(5 - 3.32) \text{ g}$   
=  $1.68 \text{ g}$ 

**Problem 36.** A mixture of formic acid and oxalic acid is heated with conc.  $H_2SO_4$ . The gas produced is collected and on its treatment with KOH solution the volume of the gas decreases by one sixth. Calculate the molar ratio of the two acids in the original mixture. [Roorkee 1990]

#### **Solution:**

The reactions of the acids may be represented by the following equations:

Let the total volume of the gas collected be V litre. On passing through KOH solution,  $CO_2$  is absorbed and the volume of the gas decreases by one sixth.

Volume of CO<sub>2</sub> in the mixture = 
$$\frac{V}{6}$$
  
Volume of total CO =  $V - \frac{V}{6} = \frac{5V}{6}$ 

Volume of CO produced from  $H_2C_2O_4 = V/6$ 

Volume of CO produced from HCOOH 
$$=\frac{5V}{6} - \frac{V}{6} = \frac{4V}{6}$$

Moles of CO produced from HCOOH = 
$$\frac{4V}{6} \times \frac{1}{22.4}$$

Moles of CO produced from 
$$H_2C_2O_4 = \frac{V}{6} \times \frac{1}{22.4}$$

Thus,

$$\frac{\text{Moles of HCOOH}}{\text{Moles of H}_2\text{C}_2\text{O}_4} = \frac{\text{Moles of CO produced from HCOOH}}{\text{Moles of CO produced from H}_2\text{C}_2\text{O}_4}$$

$$=\frac{\frac{4V}{6} \times \frac{1}{22.4}}{\frac{V}{6} \times \frac{1}{22.4}} = \frac{4}{1}$$

The formic acid and oxalic acid in the original mixture are in the molar ratio of 4:1.

**Problem 37.** Chlorine gas can be produced in the laboratory by the reaction,

 $K_2Cr_2O_7 + 14HCl \longrightarrow 2KCl + 2CrCl_3 + 7H_2O + 3Cl_2$  if a 61.3 g sample that is 96%  $K_2Cr_2O_7$  is allowed to react with 320 mL of hydrochloric acid solution having a density 1.15 g mL<sup>-1</sup> and containing 30% HCl by mass, what mass of  $Cl_2$  is generated?

#### **Solution:**

The desired equation is:

$$\begin{array}{c} K_{2}Cr_{2}O_{7} + 14HC1 \longrightarrow 2KC1 + 2CrCl_{3} + 7H_{2}O + 3Cl_{2} \\ 294 \text{ g} & 14 \times 36.5 \text{ g} & 3 \times 71 \text{ g} \\ \\ \text{Mass of } K_{2}Cr_{2}O_{7} = \frac{96}{100} \times 61.3 = 58.848 \text{ g} \\ \end{array}$$

Mass of HCl= 
$$\frac{30}{100} \times 320 \times 1.15 = 110.4 \text{ g}$$
  
294 g K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> react with HCl = 511.0 g  
58.848 g K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> would react with HCl= $\frac{511.0}{294.0} \times 58.848 \text{ g}$   
= 102.28 g

Thus, K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is a limiting reagent whereas HCl is present in excess.

294 g K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> produce chlorine = 
$$3 \times 71$$
 g  
58.848 g K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> would produce chlorine =  $\frac{3 \times 71}{294.0} \times 58.848$  g  
= 42.63 g

**Problem 38.** Gasteric juice contains 3.0 g HCl per litre. If a person produces 2.5 litre of gasteric juice per day, how many antacid tablets containing 400 mg of Al(OH)<sub>3</sub> are needed to neutralise all the acid produced per day? [Dhanbad 1991]

#### Solution:

2.5 litre of gasteric juice contain  $HCl = 2.5 \times 3 = 7.5$  g The desired equation is :

$$\begin{array}{ccc} Al(OH)_3 + & 3HCl \longrightarrow AlCl_3 + 3H_2O \\ & 1 & \text{mole} & 3 & \text{mole} \\ & 78 & g & 3 \times 36.5 & g \end{array}$$

 $3 \times 36.5$  g HCl is completely neutralised by 78 g Al(OH)<sub>3</sub> 7.5 g HCl would be completely neutralised by Al(OH)<sub>3</sub>

$$= \frac{78}{3 \times 365} \times 75 = 5.342 \text{ g}$$

No. of tablets of Al(OH)<sub>3</sub> =  $\frac{5.342}{0.4}$  = 13.36 ≈ 14

**Problem 39.** A mixture of 20 mL of CO, CH<sub>4</sub> and  $N_2$  was burnt in excess of oxygen resulting in reduction of 13 mL by volume. The residual gas was then treated with KOH solution to show a contraction of 14 mL in volume. Calculate volume of CO, CH<sub>4</sub> and  $N_2$  in mixture. All measurements are made at constant pressure and temperature. [I.I.T. 1995]

#### Solution:

Let 'a' mL CO, 'b' mL CH<sub>4</sub> and 'c' mL  $N_2$  be present in the gaseous mixture.

$$a + b + c = 20 \text{ mL}$$
 ... (i)

The desired reactions are:

$$\begin{array}{ccccc} CO + \frac{1}{2}O_2 & \longrightarrow & CO_2 \\ 1 & \text{vol} & 1/2 & \text{vol} & 1 & \text{vol} \\ \text{'a'} & \text{vol} & \text{'a'/2} & \text{vol} & \text{'a'} \text{vol} \\ \end{array}$$

$$\begin{array}{cccc} CH_4 + 2O_2 & \longrightarrow & CO_2 + 2H_2O \\ 1 & \text{vol} & 2 & \text{vol} & 1 & \text{vol} \\ \text{'b'} & \text{vol} & \text{'2b'} & \text{vol} & \text{'b'} \text{vol} \end{array}$$

CO<sub>2</sub> is absorbed by KOH.

Thus, 
$$a + b = 14 \text{ mL}$$
 ... (ii)

From equations (i) and (ii), c = 6 mL, *i.e.*,  $N_2$  in mixt. = 6 mL

$$a + b + c + \text{vol. of } O_2 \text{ taken } - \text{vol. of } O_2 \text{ left } - (a + b) - c$$
  
= 13 mL

or vol. of 
$$O_2$$
 taken – vol. of  $O_2$  left = 13 mL

or vol. of 
$$O_2$$
 used = 13 mL  
or  $\frac{a}{2} + 2b = 13$ mL  
or  $a + 4b = 26$  mL ... (iii)

Solving equations (ii) and (iii),

$$a = 10 \text{ mL}, b = 4 \text{ mL}$$

Vol. of CO = 10 mL; vol. of  $CH_4 = 4$  mL; vol. of nitrogen = 6 mL.

**Problem 40.** A mixture of ethane  $(C_2H_6)$  and ethene  $(C_2H_4)$  occupies 40 litre at 1.00 atm. and at 400 K. The mixture reacts completely with 130 g of  $O_2$  to produce  $CO_2$  and  $H_2O$ . Assuming ideal gas behaviour, calculate the mole fractions of  $C_2H_4$  and  $C_2H_6$  in the mixture. [I.I.T. 1995]

#### **Solution:**

or

Volume of gaseous mixture at N.T.P. conditions is:

$$V = \frac{40 \times 1}{400} \times \frac{273}{1} = 27.3$$
 litre

Let 'x' litre of  $C_2H_4$  and (27.3 - x) litre of  $C_2H_6$  be present in the mixture.

Mole fraction of 
$$C_2H_4 = \frac{x}{27.3}$$
.  
Mole fraction of  $C_2H_6 = \frac{27.3 - x}{27.3}$ 

The desired equations are:

Total volume of oxygen used

$$= \left\{ 3x + \frac{7}{2}(27.3 - x) \right\} \text{ litre}$$
Mass of oxygen used =  $\frac{(7 \times 27.3 - x)}{2 \times 22.4} \times 32$ 

$$\frac{(7 \times 27.3 - x)}{1.4} = 130 \qquad \text{(Given)}$$

$$191.1 - x = 130 \times 1.4$$

$$x = 9.1$$

Mole fraction of  $C_2H_4 = \frac{9.1}{27.3} = 0.33$ 

Mole fraction of 
$$C_2H_6 = \frac{27.3 - 9.1}{27.3} = 0.66$$

**Problem 41.** Equal masses of mercury and iodine are allowed to react completely to form a mixture of mercurous and mercuric iodides. Calculate the ratio of the masses of mercurous and mercuric iodides formed. [I = 127; Hg = 201]

**Solution:** The required equations are:

**Problem 48.** A precipitate of AgCl and AgBr weighs 0.4066 g. On heating in a current of chlorine, the AgBr is converted to AgCl and the mixture loses 0.0725 g in mass. Find the percentage of chlorine in the original mixture.

#### Solution:

Let the masses of AgCl and AgBr in the original mixture be 'a' gram and 'b' gram respectively.

$$a + b = 0.4066$$
 ...(i)  
AgBr  $\xrightarrow{\text{Cl}_2}$  AgCl  
188 g 143.5 g

188 g AgBr changes to 143.5g AgCl

'b' g AgBr changes to  $=\frac{143.5}{188} \times b$  g AgCl

Total mass of AgCl after conversion

$$= a + \frac{143.5}{188} \times b = (0.4066 - 0.0725)$$

or 
$$a + \frac{143.5b}{188} = 0.3341$$
 ...(ii)

Solving eqs. (i) and (ii),

$$a = 0.1007 \text{ g}$$
  
 $b = 0.3059 \text{ g}$ 

Percentage of chlorine in the original mixture

$$=\frac{35.5\times0.1007\times100}{143.5\times0.4066}=6.13$$

### -••• PRACTICE PROBLEMS -•••-

### **■ Subjective Type Questions**

1. 13.4 g of a sample of a salt Na<sub>2</sub>SO<sub>4</sub>·xH<sub>2</sub>O was found to contain 6.3 g of water. Determine the number of molecules of water of crystallisation.

[Ans. 7 water molecules]

**2.** How much potassium chlorate is needed to obtain 2.4 litre oxygen at N.T.P.?

[Ans. 8.75 g]

**3.** Calculate the volume of carbon dioxide obtained at N.T.P. by heating 8.4 g of sodium bicarbonate.

[Ans. 1.12 litre]

**4.** Calculate the volume of air needed for the combustion of 1 kg of carbon.

[Hint: 100 parts of air contain 21 parts of oxygen by volume.] [Ans. 8888.9 litre]

- 5. What weight of chalk containing 60% CaCO<sub>3</sub> would be required for obtaining 200 litres of CO<sub>2</sub> at N.T.P.?
  [Ans. 1.488 kg]
- 6. How many grams of oxygen will be formed by the action of 12 g of sodium peroxide on water? Calculate also the volume of the gas at N.T.P.

[Ans. 2.462 g, 1.7234 litre]

- 7. Calculate the weight of lime (CaO) that can be obtained by heating 200 kg of limestone which is 93% pure.

  [Ans. 104.16 kg]
- **8.** What weight of zinc will react with dilute H<sub>2</sub>SO<sub>4</sub> to liberate 1000 mL of hydrogen at 27°C and 750 mm pressure? [Zn = 65]

[Ans. 2.6 g of zinc]

**9.** What weight of AgCl will be precipitated when a solution containing 4.77 g of NaCl is added to a solution of 5.77 g of AgNO<sub>3</sub>?

[Hint: AgNO<sub>3</sub> is the limiting reagent in this problem.] [Ans. 4.87 g AgCl]

How much of iron can be theoretically obtained by the reduction of 1 kg of Fe<sub>2</sub>O<sub>3</sub>? [Fe = 56][Ans. 700 g]

11. Caustic soda is often prepared commercially by the reaction of Na<sub>2</sub>CO<sub>3</sub> with slaked lime, Ca(OH)<sub>2</sub>. How many grams of NaOH can be obtained by treating 2 kg of Na<sub>2</sub>CO<sub>3</sub> with Ca(OH)<sub>2</sub>?

[Ans. 1.51 kg]

**12.** Most of the commercial hydrochloric acid is prepared by heating NaCl with concentrated H<sub>2</sub>SO<sub>4</sub>. How much sulphuric acid containing 90% H<sub>2</sub>SO<sub>4</sub> by weight is needed for the production of 1 kg of concentrated hydrochloric acid containing 42.0% HCl by weight?

[Hint: Amount of pure HCl in 1 kg of 42.0% acid is 0.42 kg. Determine the H<sub>2</sub>SO<sub>4</sub> required to produce 0.42 kg HCl. It comes to 0.564 kg. Finally, determine the H<sub>2</sub>SO<sub>4</sub> solution containing 90% H<sub>2</sub>SO<sub>4</sub>.]

[Ans.  $0.6266 \text{ kg H}_2\text{SO}_4 \text{ solution}]$ 

13. Iodine can be made by the reaction,

 $2NaIO_3 + 5NaHSO_3 \rightarrow 3NaHSO_4 + 2Na_2SO_4 + H_2O + I_2$ To produce 2 kg of iodine, how much NaIO<sub>3</sub> and how much NaHSO<sub>3</sub> must be used ?

[Ans. 3.12 kg NaIO<sub>3</sub>, 4.10 kg NaHSO<sub>3</sub>]

**14.** The reduction of Cr<sub>2</sub>O<sub>3</sub> by Al proceeds quantitatively on ignition by a suitable fuse.

$$2Al + Cr_2O_3 \longrightarrow Al_2O_3 + 2Cr$$

How much metallic chromium can be made by bringing to reaction temperature a mixture of 5.0 kg Al and  $20 \text{ kg Cr}_2\text{O}_3$ . Which reactant remains at the completion of the reaction and how much?

[Ans. 9.6 kg chromium; 5.9 kg Cr<sub>2</sub>O<sub>3</sub>]

- 15. 10 g of FeS is treated with dilute H<sub>2</sub>SO<sub>4</sub> and liberated gas is passed through an aqueous solution of CdCl<sub>2</sub>. The amount of cadmium sulphide precipitated is 14.4 g. Calculate the percentage purity of FeS. [Fe = 56; Cd = 112]
  [Ans. 88% purity]
- 16. 50 mL of a mixture of CO and H<sub>2</sub> gave 20 mL of CO<sub>2</sub> after combustion in excess of air. Determine the percentage of CO by volume in the mixture.
  [Ans. 40%]

17. A colourless gas burns with a blue flame and reduces hot copper oxide to copper. When burnt in oxygen, it produces a gas which turns lime water milky. Calculate the volume of the gas at 100°C and 1.5 atm. pressure when 50 mL of oxygen at N.T.P. is required for complete combustion.

[Ans. The gas is CO, volume = 91.08 mL]

- **18.** What volume of hydrogen measured at 27°C and 776.7 mm pressure would be obtained by treating 1.3 g of pure zinc with excess of hydrochloric acid. Aqueous tension at 27°C is  $26.7 \, \text{mm}$ , [Zn = 65][Ans. 498.86 mL]
- 19. 34 g of pure H<sub>2</sub>O<sub>2</sub> is decomposed. Calculate the weight and volume at N.T.P. of oxygen that will be evolved. [Ans. 16 g, 11.2 litre]
- 20. 6 g of an impure sample of KClO<sub>3</sub> gave 1.9 g of oxygen on strong heating in presence of a catalyst. What is the percentage purity of the sample? [Ans. Percentage purity = 80.9]
- 21. Find the percentage composition of iron and magnesium, 5.0 g, which when dissolved in acid, gave 2.81 litre of  $H_2$  at N.T.P. [Fe = 56; Mg = 24][Ans. Fe = 69.60%; Mg = 30.40%]
- 22. 10 g of an alloy of aluminium and magnesium is treated with excess of dilute HCl. The evolved hydrogen collected over mercury at 0°C has a volume of 1.2 litre at 0.29 atm. pressure. Calculate the percentage composition of the alloy. [Al = 27; Mg = 24][Ans. Al = 54.87%; Mg = 45.13%]
- 23. A mixture of calcium and magnesium carbonates weighing 1.4 g was strongly heated until no further loss of weight was perceived. The residue weighed 0.76 g. What percentage of MgCO<sub>3</sub> was present in the mixture? [Ans. 20.45%]
- 24. A mixture of NaI and NaCl gave with H<sub>2</sub>SO<sub>4</sub>, Na<sub>2</sub>SO<sub>4</sub> equal in weight to the original mixture taken. Find the percentage composition of the mixture.

[Hint: 
$$2\text{NaI} + \text{H}_2\text{SO}_4 \longrightarrow \text{Na}_2\text{SO}_4 + 2\text{HI}$$
  
 $2 \times 150\text{g}$   $142\text{g}$   
 $2\text{NaCl} + \text{H}_2\text{SO}_4 \longrightarrow \text{Na}_2\text{SO}_4 + 2\text{HCl}$   
 $2 \times 58.5 \text{ g}$   $142 \text{ g}$ 

Let 100 g of the mixture be taken 'a' g NaI and (100 - a)g NaCl are present. Quantity of Na2SO4 formed is:

$$\frac{142}{300} \times a + \frac{142}{117} (100 - a) = 100$$
 ]

[Ans. 28.86% NaI; 71.14% NaCl]

- 25. How much potassium chlorate must be strongly heated to get as much oxygen as would be obtained from 10.8 g of mercuric oxide? [K = 39; Cl = 35.5; Hg = 200][Ans. 2.04 g KC1O<sub>3</sub>]
- 26. What will be the ratio of the yields of hydrogen prepared by the action of (i) dilute HCl and (ii) super-heated steam on the same amount of metallic iron? [Ans. The ratio is 3:4.]

27. How many grams of cupric oxide will be completely reduced by hydrogen gas produced from 6.53 g of zinc by boiling it with excess of NaOH solution? [Zn = 65.3; Cu = 63.5]

[Hint: The required reactions are:

$$Zn + 2NaOH \longrightarrow Na_2ZnO_2 + H_2$$

$$65.3 g \qquad \qquad 2 g$$

$$CuO + H_2 \longrightarrow Cu + H_2O]$$

$$79.5 g \quad 2 g$$

[Ans. 7.95 g]

28. 6 grams of an impure sample of NH<sub>4</sub>Cl were boiled with excess of alkali till all the ammonia was released. The issuing gas was completely neutralised by 20 mL of a dilute H2SO4 solution of specific gravity 1.16 and containing 22.19% of H<sub>2</sub>SO<sub>4</sub> by weight in it. What is the percentage purity of the sample of ammonium chloride?

[**Hint :** Amount of 
$$H_2SO_4 = \frac{22.19}{100} \times 20 \times 1.16 = 5.148 g$$
  
The required equations are :

$$2NH_3 + H_2SO_4 \longrightarrow (NH_4)_2SO_4$$

$$34 \text{ g} \qquad 98 \text{ g}$$

$$NH_3 \text{ neutralised by } 5.148 \text{ g } H_2SO_4 = \frac{34}{98} \times 5.148 = 1.786 \text{ g}$$

$$NH_4Cl + NaOH \longrightarrow NH_3 + NaCl + H_2O$$

NH<sub>4</sub>Cl required to produce 1.786 g NH<sub>3</sub> = 
$$\frac{53.5}{17} \times 1.786$$
  
- 5.62 g

Percentage purity = 
$$\frac{5.62}{6.0} \times 100 = 93.67$$
]

29. 0.5 g of pyrolusite (naturally occurring MnO<sub>2</sub>) were boiled with excess of conc. HCl and the issuing gas was passed through a solution of potassium iodide, when 0.635 g of iodine were liberated. What was the percentage of pure  $MnO_2$  in the pyrolusite sample ? [Mn = 55; Cl = 35.5; K=39; I = 1271

[Hint: Required equations are:

$$\begin{array}{c} MnO_2 + 4HCl \longrightarrow MnCl_2 + 2H_2O + Cl_2 \\ Cl_2 + 2KI \longrightarrow 2KCl + I_2 \end{array}$$

[Ans. 43.5]

i.e.,

**30.** A mixture of cuprous oxide (Cu<sub>2</sub>O) and cupric oxide (CuO) was found to contain 88% copper. Calculate the amount of each oxide in 5 g sample of the mixture. [Cu = 64]

[Hint: Let a g of  $Cu_2O$  and (100 - a) g of CuO be present in 100 g of the mixture. The required equations are:

$$\begin{array}{c} \text{Cu}_2\text{O} + \text{C} \longrightarrow 2\text{Cu} + \text{CO} \\ 144 \text{ g} & 128 \text{ g} \\ \text{CuO} + \text{C} \longrightarrow \frac{\text{Cu}}{64 \text{ g}} + \text{CO} \\ 80 \text{ g} & 64 \text{ g} \\ \end{array}$$

$$\frac{128}{144} \times a + \frac{64}{80}(100 - a) = 88 \qquad \text{(Given } a = 90 \\ a = 90 \\ \text{i.e.,} & \text{Cu}_2\text{O} = 90 \text{ g} \quad \text{and} \quad \text{CuO} = 10 \text{ g} \\ \text{[Ans. Cu}_2\text{O} = 4.5 \text{ g}; \quad \text{CuO} = 0.5 \text{ g}] \end{array}$$

31. 10 mL of a gaseous hydrocarbon were burnt completely in 80 mL of O<sub>2</sub> at N.T.P. The remaining gas occupied 70 mL at N.T.P. The volume becomes 50 mL on treatment with KOH. What is empirical formula of hydrocarbon?

[Hint: 
$$C_xH_y + (x + y/4)O_2 \longrightarrow xCO_2 + y/2H_2O$$
  
1 vol  $(x + y/4)$  vol  $x$  vol  $y/2$  vol  
10 mL  $10(x + y/4)$  mL  $10x$  mL  $zero$   
 $CO_2$  produced  $= (70 - 50) = 20$  mL  
Unreacted oxygen  $= 50$  mL  
Oxygen used  $= 30$  mL  
So,  $10x = 20$  or  $x = 2$   
 $10\left(x + \frac{y}{4}\right) = 30$   
or  $x + \frac{y}{4} = 3$  or  $\frac{y}{4} = 1$  or  $y = 4$ ]  
[Ans.  $C_2H_4$ ]

32. Find the resultant volumes measured at the same temperature and pressure when (i) 10 mL of carbon monoxide are exploded with 25 mL of oxygen and (ii) 10 mL of oxygen are exploded with 25 mL of carbon monoxide.

[Ans. (i) 
$$O_2 = 20 \text{ mL}$$
,  $CO_2 = 10 \text{ mL}$ , (ii)  $CO = 5 \text{ mL}$ ,  $CO_2 = 20 \text{ mL}$ ]

- 33. 12 mL of a gaseous hydrocarbon are exploded with excess of oxygen. The contraction observed is 30 mL. When treated with a solution of KOH, there is further contraction of 24 mL. What is the molecular formula of the hydrocarbon? [Ans. C<sub>2</sub>H<sub>6</sub>]
- 34. 500 mL of a hydrocarbon burnt in excess of oxygen, yield 2500 mL of CO<sub>2</sub> and 3.0 litre of water vapours. All the volumes being measured at the same temperature and pressure. What is the formula of the hydrocarbon?
  [Ans. C<sub>5</sub>H<sub>12</sub>]
- 35. Ca(OH)<sub>2</sub> + 2NH<sub>4</sub>Cl = CaCl<sub>2</sub> + 2NH<sub>3</sub> + 2H<sub>2</sub>O Find from the above equation the amount in grams of NH<sub>4</sub>Cl required to produce 2.024 litre of NH<sub>3</sub> at 750 mm pressure and 0°C. Also find the weight of CaCl<sub>2</sub> produced. [Ans. 4.78 g NH<sub>4</sub>Cl; 4.96 g CaCl<sub>2</sub>]
- 36. 1.4 g of a sample of marble (CaCO<sub>3</sub>) containing silica as impurity, gave 282 mL of carbon dioxide at 15°C and 767 mm pressure, when treated with excess of dilute HCl. Calculate the percentage of impurity in the sample.
  [Ans. Percentage of impurity = 14]
- 37. 60 mL of a mixture of carbon monoxide and hydrogen were mixed with 40 mL of oxygen and the mixture was exploded in an eudiometer. After cooling, the volume was found to be 30 mL. Find the composition of the original mixture. (Volumes are measured at the same temperature and pressure.)

[Hint: Let x mL of CO and (60 - x) mL of H<sub>2</sub> be present in the original mixture.

(i) 
$$2\text{CO} + \text{O}_2 \longrightarrow 2\text{CO}_2$$

$$2 \text{ vol} \quad 1 \text{ vol} \quad 2 \text{ vol}$$

$$x \qquad \frac{x}{2} \qquad x$$
(ii) 
$$2\text{H}_2 + \text{O}_2 \longrightarrow \text{H}_2\text{O}$$

$$2 \text{ vol} \quad 1 \text{ vol} \quad 0 \text{ vol}$$

$$(60 - x) \qquad \frac{(60 - x)}{2} \text{ after cooling}$$

$$\text{Oxygen used} = \frac{x}{2} + \frac{60 - x}{2} = 30 \text{ mL}$$

$$\text{Residual oxygen} = 40 - 30 = 10 \text{ mL}$$

$$\text{Vol of CO}_2 + \text{Residual oxygen} = x + 10 = 30$$

$$\text{or} \qquad \qquad x = 20$$

$$\text{CO'volume} = 20 \text{ mL}; \text{H}_2 \text{ volume} = 40 \text{ mL}$$

- 38. A mixture of marsh gas (CH<sub>4</sub>) and acetylene requires 22 mL of oxygen for complete combustion and produces 14 mL of carbon dioxide. Find the volume of each component in the mixture when all the volumes are measured at N.T.P.

  [Ans. CH<sub>4</sub> = 6 mL; C<sub>2</sub>H<sub>2</sub> = 4 mL]
- 39. 100 mL of a mixture of carbon monoxide, methane and hydrogen are mixed with 300 mL of oxygen and fired. After cooling the resultant gas occupied 285 mL and after absorption by potash 205 mL of oxygen remained. Find the composition of the mixture if all the volumes are measured under the same conditions of temperature and pressure.

  [Ans. CO = 50 mL; CH<sub>4</sub> = 30 mL; H<sub>2</sub> = 20 mL]
- 40. What weight of oxalic acid crystals (C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>·2H<sub>2</sub>O), on being heated with excess of conc. H<sub>2</sub>SO<sub>4</sub> would give 1 litre of the mixture of gases at N.T.P.? What volume of gaseous product would be obtained at N.T.P. by (i) burning the above mixture of gases and (ii) passing the mixture of gases repeatedly over red hot carbon?

[Ans. 2.81 g; (i) 1 litre (ii) 1.5 litre]

41. Igniting MnO<sub>2</sub> converts it quantitatively to Mn<sub>3</sub>O<sub>4</sub>. A sample of pyrolusite is of the following composition: MnO<sub>2</sub> 80%; SiO<sub>2</sub> and other inert constituents 15% and rest being water. The sample is ignited in air the constant weight. What is the percentage of Mn in the ignited sample?

$$[Mn = 54.9, O = 16]$$

[Hint : First determine the amount of  $Mn_3O_4$  from 80 g of  $MnO_2$ . It comes to 70.2 g. Total residue 70.2 + 15.0 = 85.2 g

% of Mn<sub>3</sub>O<sub>4</sub> in the ignited sample = 
$$\frac{70.2}{85.2} \times 100$$
= 82.4

% of Mn in the ignited sample = 
$$\frac{3 \times 54.9}{228.7} \times 82.4 = 59.36$$
 ]

**42.** A 2.0 g of sample containing Na<sub>2</sub>CO<sub>3</sub> and NaHCO<sub>3</sub> loses 0.248 g when heated to 300°C. What is the percentage of Na<sub>2</sub>CO<sub>3</sub> in the mixture?

[Hint: On heating only NaHCO3 is decomposed.]

[Ans. % of  $Na_2CO_3 = 66.4$ ]

43. 25.4 g of iodine and 14.2 g of chlorine are made to react completely to yield a mixture of ICl and ICl<sub>3</sub>. Calculate the number of moles of ICl and ICl<sub>3</sub> formed.

[Hint: 
$$I_2$$
 +  $2Cl_2 \longrightarrow ICl_3$  +  $ICl_3$ ]
254 g 142 g 1 mole 1 mole

[Ans. 0.1 mole IC1<sub>3</sub> and 0.1 mole IC1.]

- 44. 2.68 g of a mixture of CaCO<sub>3</sub>, MgCO<sub>3</sub> and NaHCO<sub>3</sub> suffered a loss of 1.19 g on heating. The residue on treatment with excess of hydrochloric acid gave 0.112 litre of CO<sub>2</sub> as measured at N.T.P. Calculate the weight of each component.
  [Ans. CaCO<sub>3</sub> = 1 g; MgCO<sub>3</sub> = 0.84 g; NaHCO<sub>3</sub> = 0.84 g]
- **45.** Crude calcium carbide is made in electric furnace by the following reaction,

$$CaO + 3C \longrightarrow CaC_2 + CO$$

The product contains 85% CaC<sub>2</sub> and 15% unreacted CaO.

- (a) How much CaO is to be added to the furnace charge for each 1000 kg of CaC<sub>2</sub> (pure)?
- (b) How much CaO is to be added to the furnace charge for each 1000 kg of crude product?

[Hint: (a) For getting 1000 kg pure CaC2, the CaO required  $=\frac{56}{64} \times 1000 = 875 \text{ kg}$ 

Free CaO present = 
$$\frac{15 \times 1000}{85}$$
 = 176.47 kg

Total = 875 + 176.47 = 1051.47 kg

(b) 1000 kg crude product consists 850 kg CaC2 and 150 kg CaO.

CaO required for 850 kg 
$$CaC_2 = \frac{56}{64} \times 850 = 743.75$$
 kg  
Total = 743.75 + 150 = 893.75 kg

46. A fluorine disposal plant was constructed to carry out the reactions.

$$F_2 + 2NaOH \longrightarrow 2NaF + H_2O + \frac{1}{2}O_2$$
  
 $2NaF + CaO + H_2O \longrightarrow CaF_2 + 2NaOH$ 

As the plant operated, excess lime was added to bring about complete precipitation of the fluorides as CaF2. Over a period of operation 2000 kg of fluorine was fed into the plant and 10000 kg of lime was required. What was the percentage utilization of lime?

38 g fluorine require CaO = 56 g

$$2000 \times 1000$$
 g fluorine require CaO =  $\frac{56}{38} \times 2000 \times 1000$   
=  $\frac{56}{19} \times 10^6$  g  
% utilization =  $\frac{56}{19} \times \frac{10^6}{10^7} \times 100 = 29.5$ ]

- 47. 20 mL solution containing 0.20 g of an impure sample of H<sub>2</sub>O<sub>2</sub> reacts with 0.316 g of KMnO<sub>4</sub> in presence of H<sub>2</sub>SO<sub>4</sub>.
  - (i) Find the purity of hydrogen peroxide sample.
  - (ii) Calculate the volume of dry oxygen evolved at 27°C and 750 mm pressure.

[Hint: 
$$2KMnO_4 + 3H_2SO_4 + 5H_2O_2 = K_2SO_4 + 2MnSO_4$$
  
 $_{316 \text{ g}}$   $_{170$ 

[Ans. Purity 85%; 124.72 mL]

48. How many kilograms of pure H<sub>2</sub>SO<sub>4</sub> could be obtained from 1 kg of iron pyrite (FeS<sub>2</sub>) according to the following reactions? [Fe = 56]

$$\begin{array}{c} 4\text{FeS}_2 + 11\text{O}_2 \longrightarrow 2\text{Fe}_2\text{O}_3 + 8\text{SO}_2 \\ 2\text{SO}_2 + \text{O}_2 \longrightarrow 2\text{SO}_3 \\ \text{SO}_3 + \text{H}_2\text{O} \longrightarrow \text{H}_2\text{SO}_4 \end{array}$$

[**Ans.** 1.63 kg]

49. When 60 mL of a mixture of N<sub>2</sub>O and NO were mixed with an equal volume of pure H2 and exploded, 38 mL of N2 were left. Calculate the volume of each gas present in the original

[Ans. 
$$N_2O = 16 \text{ mL}$$
;  $NO = 44 \text{ mL}$ ]

**50.** Carbon disulphide, CS<sub>2</sub>, can be made from byproduct SO<sub>2</sub>. The overall reaction is,

$$5C + 2SO_2 \longrightarrow CS_2 + 4CO$$

How much CS<sub>2</sub> can be produced from 450 kg of waste SO<sub>2</sub> with excess of coke, if the SO<sub>2</sub> conversion is 82%? [Ans. 219 kg]

51. A mixture containing NaHCO<sub>3</sub> and Na<sub>2</sub>CO<sub>3</sub> weighed 1.0235 g. The dissolved mixture was reacted with excess of Ba(OH)<sub>2</sub> to form 2.1028 g BaCO<sub>3</sub> by the reactions,

$$Na_2CO_3 + Ba(OH)_2 \longrightarrow BaCO_3 + 2NaOH$$
  
 $NaHCO_3 + Ba(OH)_2 \longrightarrow BaCO_3 + NaOH + H_2O$   
What is the percentage of NaHCO<sub>3</sub> in the mixture?

[Ba = 137]

[Ans. 39.51%]

52. A blackened silver coin weighing 15 g on treatment with HCl vielded 25 mL of H<sub>2</sub>S at 12°C and 775 mm pressure. What percentage of original silver tarnished?

[Ans. 1.57%]

53. Brass is an alloy of copper and zinc. A sample of brass weighing 5.793 g when treated with excess of dilute sulphuric acid gave 324 mL of hydrogen at 20°C and 750 mm pressure. What is the percentage by weight of copper in the alloy? [Hint: Only zinc will react with dilute H<sub>2</sub>SO<sub>4</sub> to give hydrogen] [Ans. 85.025% copper]

54. Polyethylene is obtained according to following sequence of reactions.

$$CaC_2 + H_2O \longrightarrow CaO + C_2H_2$$
  
 $C_2H_2 + H_2 \longrightarrow CH_2 = CH_2$   
 $nCH_2 = CH_2 \longrightarrow (-CH_2 - CH_2 -)_n$ 

Find out the mass of polyethylene which can be obtained from 10 kg of calcium carbide.

[Hint: The mass of polyethylene is same as the mass of ethylene.] [Ans. 4.375 kg]

55. 1.0 g of a mixture of potassium chloride and potassium iodide dissolved in water and precipitated with silver nitrate, gave 1.618 g of silver halides. Calculate the percentage of each in the mixture, [K = 39, Cl = 35.5, I = 127, Ag = 108][Ans. % KCl = 39.6; % KI = 60.4]

50 mL of dry ammonia gas was sparked for a long time in an eudiometer tube over mercury. After sparking the volume becomes 97 mL. The gaseous mixture is washed with water and after drying, the volume becomes 94 mL. This was mixed with 60.5 mL of oxygen and the mixture was burnt. After the completion of the combustion of H<sub>2</sub>, the volume of the residual gas was 48.75 mL. Derive the molecular formula of ammonia.

[Hint: Let the formula be N<sub>x</sub>H<sub>y</sub>.

Thus,

Initial vol. 
$$N_x H_y \Longrightarrow (x/2) \ N_2 + (y/2) \ H_2$$
Initial vol.  $50 \text{ mL}$   $0$   $0$ 
Final vol.  $(50-a) \text{ mL}$   $\frac{ax}{2}$   $\frac{ay}{2}$ 

i.e.,  $(50-a) + \frac{ax}{2} + \frac{ay}{2} = 97$ 

After washing,  $\frac{ax}{2} + \frac{ay}{2} = 94$ 

or  $50-a=3$ 

or  $a=47 \text{ mL}$ 

Thus,  $N_2 = \frac{47x}{2}$  and  $H_2 = \frac{47y}{2}$ 

or 
$$x + y = 4 \qquad \dots(i)$$

$$H_2 + \frac{1}{2}O_2 \longrightarrow H_2O$$

$$\frac{47y}{2} \qquad 60.5 \qquad 0$$

$$0 \qquad \left(60.5 - \frac{47y}{4}\right)$$

Residual gases after combustion =  $N_2 + O_2$  left

$$48.75 = \frac{47x}{2} + 60.5 - \frac{47y}{4} \qquad \dots (ii)$$

Solving (i) and (ii),

$$x = 1$$
 and  $y = 3$ 

Formula is NH3.]

- **57.** 3.2 g of a mixture of KNO<sub>3</sub> and NaNO<sub>3</sub> was heated to constant weight which was found to be 2.64 g. What is the % of KNO<sub>3</sub> in mixture?

  [Ans. 44.22%]
- 58. 3 g sample of blue vitriol (CuSO<sub>4</sub>:5H<sub>2</sub>O) were dissolved in water. BaCl<sub>2</sub> solution was mixed in excess to this solution. The precipitate obtained was washed and dried. It weighed 2.82 g. Determine % of SO<sub>4</sub><sup>2-</sup> by weight in sample. [Ans. 38.72%]
- **59.** 0.260 g sample of limestone is dissolved and calcium is precipitated as calcium oxalate CaC<sub>2</sub>O<sub>4</sub>. After filtration and washing the precipitate, its required 20 mL of 0.05 *M* KMnO<sub>4</sub> solution acidified with sulphuric acid to titrate. What is the percentage of CaO in the limestone?

[Hint: 
$$CaCO_3 \longrightarrow CaO \longrightarrow CaC_2O_4$$
  
1 mole 1 mole 2 mole 2 mole 5 mole  $CaC_2O_4 \longrightarrow CaC_2O_4 
[Ans. 53.8%]

**60.** The chromate ion may be present in waste water from a chrome plating plant. It is reduced to insoluble chromium hydroxide, Cr(OH)<sub>3</sub>, by dithionite ion, S<sub>2</sub>O<sub>4</sub><sup>2-</sup> in basic solution according to following equation:

 $3S_2O_4^{2-} + 2CrO_4^{2-} + 2H_2O + 2OH^- \longrightarrow 6SO_3^{2-} + 2Cr(OH)_3$ 200 L of water require 774 g of Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>. Calculate molarity and normality of  $CrO_4^{2-}$  in waste water.

[**Hint**: Number of moles of  $Na_2S_2O_4 = \frac{774}{174} = 4.448$  mole;

Number of moles of  $CrO_4^{2-} = \frac{2}{3} \times 4.448 = 2.965$  mole]

[Ans. Molarity = 0.0148 M; Normality = 0.0444 N]

- 61. A welding fuel gas contains carbon and hydrogen only. Burning a small sample of it in oxygen gives 3.38 g carbon dioxide, 0.69 g of water and no other products. A volume of 10 L (measured at S.T.P.) of this welding gas is found to weigh 11.6 g. Calculate:
  - (i) empirical formula
  - (ii) molar mass of the gas and
  - (iii) molecular formula.

[Ans. (i) CH; (ii)  $26 \text{ g mol}^{-1}$ ; (iii)  $C_2H_2$ ]

**62.** A mixture of FeO and Fe<sub>3</sub>O<sub>4</sub> when heated in air to a constant weight gains 5% in its weight. Find the composition of initial mixture.

[Ans. FeO (20.25%), Fe<sub>3</sub>O<sub>4</sub> (79.75%)]

63. Superphosphate of lime can be synthesised as:

$$5Ca_3(PO_4)_2 + 11H_2SO_4 \longrightarrow 4Ca(H_2PO_4)_2 + 2H_3PO_4 + 11CaSO_4$$

- (a) How much H<sub>2</sub>SO<sub>4</sub> is required to convert 2g Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> by this reaction?
- (b) Calculate amount of superphosphate of lime obtained from 2 g of Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub> by this reaction.

[Ans. (a) 1.39 g; (b) 3.39 g]

- **64.** Trifluoroacetic anhydride (CF<sub>3</sub>CO)<sub>2</sub>O was prepared by treating 100 g of trifluoroacetic acid (CF<sub>3</sub>COOH) with 100 g P<sub>4</sub>O<sub>10</sub>. The anhydride collected weighed 65.6 g. What was the percentage yield?

  [Ans. 71.2%]
- **65.** In the study of thermal decomposition of K<sub>3</sub>[Fe(C<sub>2</sub>O<sub>4</sub>)<sub>2</sub>]; 25 mg of the compound produced 2.24 mg of CO<sub>2</sub> along with FeC<sub>2</sub>O<sub>4</sub> and K<sub>2</sub>C<sub>2</sub>O<sub>4</sub>. Calculate % yield of carbon dioxide. [Ans. 88.9%]
- **66.** 0.105 mole of  $K_2Cr_2O_7$  are required to oxidise a mixture of XO and  $X_2O_3$  to form  $XO_4$  and  $Cr^{3+}$ . If 0.0817 mole of  $XO_4$  is formed, what is atomic mass of X? Given weight of the original mixture  $(XO + X_2O_3)$  is 2.180 g.

[Hint: Involved reactions are:

- (i)  $6XO + 5Cr_2O_7^{2-} + 34H^+ \longrightarrow 6XO_4^- + 10Cr^{3+} + 17H_2O$ (ii)  $3X_2O_3 + 4Cr_2O_7^{2-} + 26H^+ \longrightarrow 6XO_4^- + 8Cr^{3+} + 13H_2O$ [Ans. 100]
- 67. If 20 g CaCO<sub>3</sub> is treated with 20 g HCl, how many grams of CO<sub>2</sub> can be generated according to the following equation, CaCO<sub>3</sub>(s) + 2HCl(aq.) → CaCl<sub>2</sub>(aq.) + H<sub>2</sub>O(l) + CO<sub>2</sub>(g) Which one of the two reactants is limiting?

  [Ans. 8.8 g CO<sub>2</sub>; CaCO<sub>3</sub> is limiting.]
- **68.** Calculate percentage yield if the reaction of 64 g of NaBH<sub>4</sub> with iodine produced 15 g BI<sub>3</sub>.

$$NaBH_4 + 4I_2 \longrightarrow BI_3 + NaI + 4HI$$

[Ans. 2.27%]

**69.** Silver may be removed from solutions of its salts by reaction with metallic zinc according to the reaction,

$$Zn + 2Ag^{+} \longrightarrow 2Ag + Zn^{2+}$$

A 50 g piece of zinc was thrown into a 100 L vat containing 3.0 g Ag<sup>+</sup>/L.

- (a) Which reactant was completely consumed?
- (b) How much of the other substance remained unreacted?
   [Ans. (a) Zinc is completely consumed, (b) 140 g Ag<sup>+</sup> remain unreacted.
- 70. A particular 100 octane aviation gasoline used 1.00 mL of tetraethyllead, (C<sub>2</sub>H<sub>4</sub>)<sub>4</sub>Pb, of density 1.66 g/mL per litre of product. This compound is made as follows:

$$4C_2H_5Cl + 4NaPb \longrightarrow (C_2H_5)_4Pb + 4NaCl + 3Pb$$

How many gram of ethyl chloride is needed to make enough tetraethyllead for 1 L of gasoline?

[Atomic mass of Pb = 207]

[Hint: The mass of 1 mL  $(C_2H_5)_4Pb = 1 \times 1.66 = 1.66$  g. This is the amount needed per litre.]

[Ans.  $1.33 \text{ g C}_2\text{H}_5\text{Cl}$ ]

71. (a) How much bismuth nitrate, Bi(NO<sub>3</sub>)<sub>3</sub>·5H<sub>2</sub>O would be formed from a solution of 15 g bismuth in nitric acid?

$$Bi + 4HNO_3 + 3H_2O \longrightarrow Bi(NO_3)_3 \cdot 5H_2O + NO$$

(b) How much 30% nitric acid (containing 30% HNO<sub>3</sub> by mass) is required to react with this amount of bismuth? [Atomic mass of bismuth = 209]

[Ans. (a) 34.8 g, (b) 60.3 g solution]

72. The roasting of 100 g copper ore yielded 75.4 g of 89.5% pure copper. If the ore is composed of Cu<sub>2</sub>S and CuS with 11 % inert impurity, calculate the % of Cu<sub>2</sub>S in the ore. The equations are:

and 
$$Cu_2S + O_2 \longrightarrow 2Cu + SO_2$$
  
 $CuS + O_2 \longrightarrow Cu + SO_2$ 

[Atomic mass of copper = 63.54]

[Hint: Mass of pure copper from 100 g of copper ore

$$= \frac{75.4 \times 89.5}{100} = 67.483$$
Number of moles =  $\frac{67.483}{63.54} = 1.06$  mole Cu

In the sample, let x per cent  $Cu_2S$  and (89.0 - x) per cent CuS be present.

then, 
$$\frac{2x}{159.15} + \frac{(89.0 - x)}{95.61} = 1.06$$
]  
[Ans. Cu<sub>2</sub>S = 62%.]

73. 150 g of marble chips are dropped into one kilogram of solution of hydrochloric acid containing one tenth of its weight of the pure acid. How much chips will remain undissolved? What weight of anhydrous calcium chloride, and what weight of carbon dioxide gas would be obtained from it?

[Ans. Marble chips left undissolved = 13.014 g; CaCl<sub>2</sub> formed = 152.054 g; CO<sub>2</sub> evolved = 60.24 g]

74. Hydrogen is generated by the action of steam on hot magnesium. Calculate the mass of magnesium that will be required to produce just sufficient hydrogen to combine with all the oxygen that can be obtained by the complete decomposition of 24.5 g of KClO<sub>3</sub>.

[Ans. 14.4 g]

75. The maximum mass of copper sulphate crystals, CuSO<sub>4</sub>·5H<sub>2</sub>O obtained from 20 g of a sample of brass containing only zinc and copper is 37.2 g. What mass of zinc was present in 20 g of brass?

[Atomic masses of Cu = 63.5; S = 32; Zn = 65] [Ans. 10.53 g]

### ILLUSTRATIONS OF OBJECTIVE QUESTIONS

1. The oxygen obtained by the decomposition of 72 g  $\rm H_2O$  is :

[P.M.T. (Rai.) 2005]

(a) 72 g

(b) 46 g

(c) 50 g

(d) 64 g

Ans. (d)

[Hint: 
$$2H_2O(g) \longrightarrow 2H_2(g) + O_2$$
2 mole
36  $g$ 
1 mole

- : 36 g H<sub>2</sub>O give 32 g O<sub>2</sub> on decomposition
- ∴ 72 g H<sub>2</sub>O will give 64 g O<sub>2</sub> on decomposition]
- 2. 35.4 mL of HCl is required for the neutralization of a solution containing 0.275 g of sodium hydroxide. The molarity of hydrochloric acid is: [P.M.T. (Raj.) 2005]
  - (a) 0.97 M
- (b) 0.142 M
- (c) 0.194 M
- (d) 0.244 M

Ans. (c)

[Hint : Number of moles of NaOH =  $\frac{0.275}{40}$  =  $6.875 \times 10^{-3}$ 

Neutralization reaction:

 $HCl(aq.) + NaOH(aq.) \longrightarrow NaCl(aq.) + H_2O(l)$ 

Number of moles of HCl required for neutralization = no. of moles of NaOH

$$= 6.875 \times 10^{-3}$$

Number of moles = 
$$\frac{MV}{1000}$$

$$6.875 \times 10^{-3} = \frac{M \times 35.4}{1000}$$

M = 0.194 M

3. 2.76 g of silver carbonate on being strongly heated yield a residue weighing:

(a) 2.16 g

- (b) 2.48 g
- (c) 2.64 g
- (d) 2.32 g

Ans. (a)

[Hint: 
$$Ag_2CO_3(s) \longrightarrow 2Ag(s) + CO_2(g) + \frac{1}{2}O_2(g)$$
  

$$\begin{array}{ccc}
1 \text{ mole} & 2 \text{ mole} \\
276 \text{ g} & 2 \times 108 \\
& -216 \text{ g}
\end{array}$$

Residue obtained by heating 276 g of  $Ag_2CO_3 = 216$  g

- $\therefore$  Residue obtained by heating 2.76 g of Ag<sub>2</sub>CO<sub>3</sub> =  $\frac{216}{276} \times 2.76$
- 4. 'X' grams of CaCO<sub>3</sub> was completely burnt in air. The mass of solid residue formed is 28 g. What is the value of 'X' (in grams)?

  [E.A.M.C.E.T. (Engg.) 2005]
  - (a) 44

(b) 200

(c) 150

(d) 50

Ans. (d)

[Hint: 
$$CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$$

$$\begin{array}{ccc}
1 & \text{mole} & 1 & \text{mole} \\
100 & g & 56 & g
\end{array}$$

Residue formed by 100 g of CaCO<sub>3</sub> on decomposition = 56 g

Residue formed by 'X' g of CaCO<sub>3</sub> on decomposition = 28 g

$$\frac{56}{100} \times X = 28$$
$$X = 50 \text{ g } 1$$

- 5. 10 grams of CaCO<sub>3</sub> is completely decomposed to X and CaO. X is passed through an aqueous solution containing one mole of sodium carbonate. What is the number of moles of sodium bicarbonate formed? [E.A.M.C.E.3. 2004]
  - (a) 0.2

(b) 0.1

(c) 0.01

(d) 10

$$\begin{array}{ccc} \text{CaCO}_3 & \longrightarrow & \text{CaO} & + & \text{CO}_2 \\ \text{1 mole} & & \text{1 mole} & & (X) \\ 0.1 \text{ mole} & & & 1 \text{ mole} \\ & & & 0.1 \text{ mole} \end{array}$$

Number of moles of 
$$CaCO_3 = \frac{10}{100} = 0.1$$
  
 $Na_2CO_3 + CO_2 + H_2O \longrightarrow 2NaHCO_3$  ]

1 mole
0.1 mole
0.2 mole
0.2 mole

- 6. When 32.25 g of ethyl-chloride is subjected to dehydrohalogenation reaction, the yield of the alkene formed is 50%. The mass of the product is:
  - (a) 14 g

(c) 64.5 g

Ans. (d)

[Hint: 
$$CH_3$$
— $CH_2$ — $Cl$  — $CH_2$ — $CH_2$ + $HCl$  1 mole 64.5 g 28 g 32.25 g 14 g

Since, the yield is 50%, the actual mass of the product is 7 g.]

- 7. If 30 mL of H<sub>2</sub> and 20 mL of O<sub>2</sub> react to form water. What is left at the end of the reaction? [A.F.M.C. 2005]
  - (a)  $10 \,\mathrm{mL}\,\mathrm{of}\,\mathrm{H}_2$
- (b)  $5 \text{ mL of } H_2$
- (c)  $10 \,\mathrm{mLof} \,\mathrm{O}_2$
- (d) 5 mL of  $O_2$

Ans. (d)

Thus, 15 mL of O<sub>2</sub> is used up, hence 5 mL of O<sub>2</sub> is left at the end of the reaction.]

- 8. 100 mL of NaOH is neutralised by 10 mL of  $0.5 M H_2SO_4$ . The molarity of NaOH solution will be :
  - (a) 1

(b) 0.1

(c) 0.01

(d) 0.001

Ans. (b)

[Hint: 
$$2 \text{NaOH} + \text{H}_2 \text{SO}_4 \longrightarrow \text{Na}_2 \text{SO}_4 + 2 \text{H}_2 \text{O}_4$$
  

$$\frac{M_1 V_1}{n_1} = \frac{M_2 V_2}{n_2}$$

$$\frac{M_1 \times 100}{2} = \frac{0.5 \times 10}{1}$$

$$M_1 = \frac{0.5 \times 10 \times 2}{100} = 0.1$$

- 9. Assuming that petrol is iso-octane (C<sub>8</sub>H<sub>18</sub>) and has a density of 0.8 g mL<sup>-1</sup>, 1.425 L petrol on complete combustion will consume how much of oxygen gas at S.T.P.?
  - (a) 50 L

- (b) 125 L
- (c) 125 mole
- (d) 50 mole

Ans. (c)

[Hint: Mass of petrol =  $1425 \times 0.8 = 1140 \text{ g}$ 

Number of moles of iso-octane = 
$$\frac{1140}{114}$$
 = 10

$$C_8H_{18} + \frac{25}{2}O_2 = 8CO_2 + 9H_2O$$
]

1 mole 12.5 mole
10 mole 125 mole

- 10. Conversion of oxygen to ozone occurs to the extent of 15% only. The mass of ozone that can be prepared from 67.2 L of oxygen at S.T.P. will be:
  - (a) 14.4 g

(b) 96 g

(c) 640 g

(d) 64 g

Ans. (a)

[Hint: Number of moles of  $O_2 = \frac{67.2}{22.4} = 3$   $3O_2 = 2O_3$ 3 mole 2 mole

Since, percentage yield is 15%, number of moles of ozone formed actually from 3 moles of oxygen

$$=\frac{2\times15}{100}$$
 = 0.3 mole

Mass of ozone formed =  $0.3 \times 48 = 14.4$  g]

# **OBJECTIVE QUESTIONS**

**Note:** Choose the correct answer out of the given alternatives in each question.

1.	The percentage of nitrogen in urea is about:			
	(a) 38.4	1	(a) some ny aregon remains uncombined	
_	(c) 59.1	11.	If a mixture containing 3 mole of hydrogen and 1 mole	
2.	The mass of sulphuric acid needed to dissolve 3 g	1	nitrogen is converted completely into ammonia, the ratio	
	magnesium carbonate is:		initial and final volumes under the same temperature at	nd
	(a) $3.5 \mathrm{g}$ $\square$ (b) $7.0 \mathrm{g}$ $\square$		pressure would be:	_
	(c) $1.7 \mathrm{g}$		_ (-) - (-)	
3.	The haemoglobin from red corpuscles of most mammals		— (c) 2.1	
	contain approximately 0.33% of iron by mass. The molecular	12.	The mass of residue left after strongly heating 1.38 g of silv	/er
	mass of haemoglobin is 67200. The number of iron atoms in	1	carbonate will be:	
	each molecule of haemoglobin is:		(a) $1.16 \mathrm{g}$	
	(a) 1		_ (-)	
	(c) 3	13.	100 mL of PH <sub>3</sub> when decomposed produces phosphorus a	nd
4.	10 mL of a solution of H <sub>2</sub> O <sub>2</sub> liberated 0.5 g of I <sub>2</sub> from KI		hydrogen.The change in volume is:	
	solution. The percentage of $H_2O_2$ in the solution is:		(a) 100 mL decrease $\Box$ (b) 100 mL increase	
	(a) 0.27	1 .	(c) 50 mL increase	
	(c) 0.47	14.	7.46 g of KCl are heated in excess of H <sub>2</sub> SO <sub>4</sub> and MnO <sub>2</sub> . T	he
	[Hint: $2KI + H_2O_2 \longrightarrow 2KOH + I_2$ ]		gas evolved is passed through KI solution. The amount	of
_	34 g $2 \times 127$ g	1	iodine set free will be:	
5.	The mass of CO <sub>2</sub> obtained when 60 g of calcium carbonate	1	(a) $12.7 \text{ g}$	
	is treated with excess of hydrochloric acid is:		(c) $6.4 \mathrm{g}$	
	(a) 30.0		[Hint: $[KC1 + H_2SO_4 \longrightarrow K_2SO_4 + 2HC1] \times 2$	
6	_ (-)		$MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$	
6.	The quantity of ammonium sulphate necessary for the	-	$2KI + Cl_2 \longrightarrow 2KCl + I_2$	-
	production of ammonia gas sufficient to neutralise a		$2KCl + MnO2 + 2KI \longrightarrow 2K2SO4 + 2KCl + MnCl2 + I2$	
	solution containing 292 g of HCl is: (a) 272 g	15	$2 \times 74.5 \text{ g}$ $2 \times 127$	-
		15.	If 0.5 mole of BaCl <sub>2</sub> is mixed with 0.20 mole of Na <sub>3</sub> PO <sub>4</sub> . T	
	(c) $528 g$ $\Box$ (d) $1056 g$ $\Box$ [Hint: $NH_3 + HC1 \longrightarrow NH_4C1$ and $(NH_4)_2SO_4 = 2NH_3$ ]	}	maximum number of moles Ba <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub> that can be formed in	_
	$\begin{array}{cccccccccccccccccccccccccccccccccccc$		(a) 0.10	
7.				
	is:	16	[Note: Na <sub>3</sub> PO <sub>4</sub> is a limiting reagent.]	
	(a) 23.48	16.	2 2 2	me
	(c) 53.78	ĺ	of resulting gas is:	_
8.	The volume of oxygen required for complete oxidation of 2.0			
	litre of methane at N.T.P. is:		_ (-,	
	(a) 4 litre $\Box$ (b) 12.25 litre $\Box$	17.	1 2	om
	(c) 1 litre $\Box$ (d) 3 litre $\Box$		temperature. The final mixture of gases is:	_
9.	The % loss in mass after heating a pure sample of potassium	-		
	chlorate will be:		(c) $30 \mathrm{mL}$	
	(a) 12.25	18.	12 g of magnesium (At. mass = $24$ ) will react with an acid	l to
	(c) 39.17		give:	
	[Hint: $2KClO_3 \longrightarrow 2KCl + 3O_2$ ]	1	(a) one mole of $H_2$ $\square$ (b) one mole of $O_2$	
	2 × 122.5 g 2 × 74.5		(c) one-half mole of $H_2$ $\square$ (d) one-half mole of $O_2$	
10.	Three volumes of hydrogen are required to combine with one	19.	The mass of quick lime obtained by strongly heating 25 g	g of
	volume of nitrogen to form 2 volumes of ammonia. When		marble is:	
	one mole of hydrogen is allowed to react with one mole of		(a) 14 g	
	nitrogen, the two gases:		(c) 42 g	
	(a) do not combine	20.	A metal oxide is reduced by heating it in a stream	of
	(b) $2/3$ mole of nitrogen remains unreacted		hydrogen. It is found that after complete reduction, 3.15 g	g of

	the oxide has yielded 1.05 g of the metal. We may deduce that:	31.	Volume of oxygen needed for complete combustion of 20 mL of a hydrocarbon $C_xH_v$ will be:
	(a) the atomic mass of the metal is 8 $\Box$		(a) $(x + y/4)$ mL $\Box$ (b) $20(x + y/4)$ mL $\Box$
	(b) the atomic mass of the metal is 4		(c) $1/20(x+y/4)$ mL $\Box$ (d) none of these $\Box$
	(c) the equivalent mass of the metal is 8	32.	Hydrogen evolved at N.T.P. on complete reaction of 27 g of
	(d) the equivalent mass of the metal is 4		aluminium with excess of aqueous NaOH would be:
21			(a) 22.4 litre
21.	The mass of oxygen with which 13.5 g of aluminium will		(c) $67.2$ litre $\Box$ (d) $33.6$ litre $\Box$
	completely react, is:		[Hint: $2AI + 2NaOH + 2H_2O \longrightarrow 2NaAlO_2 + 3H_2$ ]
	(a) 4 g	33.	The volume of Cl <sub>2</sub> obtained when 4.35 g MnO <sub>2</sub> react
	(c) 12 g	55.	completely with concentrated HCl (At. mass of Mn = 55):
22.	1.6 g of an organic compound on combustion gave 4.4 g		(a) $4.48$ litre $\Box$ (b) $2.24$ litre $\Box$
	carbon dioxide. The % of carbon in organic compound is:		(c) 1.12 litre $\Box$ (d) 0.56 litre $\Box$
	(a) 30	34.	Cyclohexanol is dehydrated to cyclohexene on heating with
	(c) 60		conc. $H_2SO_4$ . If the yield of the reaction is 75%, how much
23.	At N.T.P., 10 litre of hydrogen sulphide gas reacted with 10		cyclohexene will be obtained from 100 g of cyclohexanol?
	litre of sulphur dioxide gas. The volume of gas, after the		(a) 61.5 g
	reaction is complete, would be:		(c) 20.0 g
	(a) 5 litre		[Hint: $C_6H_{11}OH \xrightarrow{-H_2O} C_6H_{10}$ ]
	(c) 15 litre $\Box$ (d) 20 litre $\Box$		100 g 82 g
24.	A substance contains 0.25% iron by mass. The molecular	35.	1 g of Mg is burnt in a closed vessel which contains 0.5 g of
	mass of substance is 89600. The number of iron atoms per		oxygen. The mass of excess reactant is:
	molecule of the substance is:		(a) $0.25 \text{ g of Mg}$ $\square$ (b) $0.33 \text{ g of O}_2$ $\square$
-	(a) 5 (b) 4		(c) $0.1 \text{ g of Mg}$ $\square$ (d) $0.25 \text{ g of O}_2$ $\square$
25	(c) 3	36.	When 1 g of zinc is treated separately with excess of H <sub>2</sub> SO <sub>4</sub>
25.	The minimum amount of hydrogen required to reduce 7.95 g		and excess of NaOH, the ratio of volume of H <sub>2</sub> evolved is:
	of CuO (Mol. mass 79.5) will be:		(a) 1:1
	(a) 2 g		(c) $2:1$
00	(c) 2240 mL at N.T.P.	37.	The mass of CaO required to remove the hardness of 10 <sup>6</sup>
26.	2.0 g mixture of sodium carbonate and sodium bicarbonate		litre of water containing 1.62 g of calcium bicarbonate per
	on heating to constant weight gave 224 mL of CO <sub>2</sub> at N.T.P.		litre is :
	The % weight of sodium bicarbonate in the mixture is:		(a) 140 kg
	(a) 50	20	(c) 420 kg
27	(c) $80$ $\square$ (d) $84$ $\square$ What volume of hydrogen at N.T.P. will be liberated when	38.	The minimum quantity of H <sub>2</sub> S in grams needed to precipitate
21.	3.25 g of zinc completely dissolve in dilute HCl? (At. mass		63.5 g of copper ions will be nearly:
	of $Zn = 65$ )		(a) 63.5 g
	(a) 1.12 litre	30	(c) $31.75 \mathrm{g}$ $\Box$ (d) $20.0 \mathrm{g}$ $\Box$ If 2 moles of $\mathrm{C_2H_5OH}$ completely burn to $\mathrm{CO_2}$ and water, the
	(c) 2.24 litre	39.	mass of carbon dioxide formed is about:
28.	The volume of oxygen at N.T.P. evolved when 1.70 g of		(a) 88 g
20.	sodium nitrate is heated to a constant mass is:		(c) $44 \text{ g}$ $\Box$ (d) $132 \text{ g}$ $\Box$
	(a) 0.112 litre	40.	The amount of ammonium nitrate that should be decomposed
	(c) 22.4 litre		for getting 22.4 litre nitrous oxide is:
29.	50 g limestone is heated. Quantity of quicklime produced is:		(a) 20 g
	(a) 56 g		(c) 60 g
	(c) 14 g	41.	and the second s
30.	Assuming that petrol is iso-octane ( $C_8H_{18}$ ) and has a density		18 g of water will be:
	of 0.8 g mL <sup>-1</sup> . 1.425 litre of petrol on combustion will		(a) 22.4 litre $\Box$ (b) 5.6 litre $\Box$
	consume:		(c) 11.2 litre
	(a) 100 moles of oxygen	42.	The percentage loss in mass on heating Na <sub>2</sub> CO <sub>3</sub> ·10H <sub>2</sub> O is:
	(b) 124 moles of oxygen □		(a) 25 %
	(c) 150 moles of oxygen		(c) 50 %
	(d) 175 moles of oxygen	43.	One mole of calcium phosphide on reaction with excess
			water gives:

[C.B.S.E. 2007]

(a) one mole of ammonia

	, ( · · · · · · · · · · · · · · · · · ·		
	(a) 1 mole of phosphine		(b) one mole of nitric acid $\Box$
	(b) 2 moles of phosphine		(c) two moles of ammonia
	(c) 2 moles of phosphoric acid		(d) two moles of nitric acid
	(d) 1 mole of phosphorus pentoxide	52.	In a balanced equation,
	[Hint: $Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3$ ]	}	$H_2SO_4 + xHI \longrightarrow H_2S + yI_2 + zH_2O$
	1 mole 2 mole		The values of $x$ , $y$ and $z$ are: [E.A.M.C.E.T. 2003]
44.	An element 'A' reacts with oxygen to produce A <sub>2</sub> O <sub>3</sub> . 1 g of		(a) $x = 3, y = 5, z = 2$
	'A' produces 1.1596 g of A <sub>2</sub> O <sub>3</sub> . Calculate atomic mass of	,	(c) $x = 8, y = 4, z = 4$ $\square$ (d) $x = 5, y = 3, z = 4$ $\square$
	element 'A' (Atomic mass of oxygen = 15.999 g mol <sup>-1</sup> ):	53.	The volume of oxygen necessary for the complete com-
	(a) 20.70		bustion of 20 L of propane is: [C.P.M.T. 2003]
	(c) 100.2		(a) 40 L
45.	Esterification of benzoic acid takes place as:		(c) 80L
	$C_6H_5COOH + CH_3OH \longrightarrow C_6H_5COOCH_3 + H_2O$	54.	How many moles of magnesium phosphate, Mg <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub> will
	Benzoic acid Methanol Methyl benzoate		contain 0.25 mole of oxygen atoms? [A.I.E.E.E. 2006]
	24.4 g benzoic acid reacts with 70 mL CH <sub>3</sub> OH (density = 0.79		(a) $0.02$ $\Box$ (b) $3.125 \times 10^{-2}$ $\Box$ (c) $-1.25 \times 10^{-2}$ $\Box$ (d) $2.5 \times 10^{-2}$ $\Box$
	g mL <sup>-1</sup> ) to produce 21.6 g of methyl benzoate. What will be		$\Box$ (c) $1.25 \times 10^{-2}$ $\Box$ (d) $2.5 \times 10^{-2}$
	the percentage yield of reaction?	1	[Hint: 8 moles oxygen = 1 mole $Mg_3(PO_4)_2$
	(a) 71.5%	}	0.25 mole oxygen will be present = $\frac{1}{8} \times 0.25$ mole
16	(c) 91.7%	ł	= 0.03125  mole
46.	1 mole N <sub>2</sub> and 4 mole H <sub>2</sub> are allowed to react in a vessel and after reaction, H <sub>2</sub> O is added to the vessel. Aqueous solution		$= 3.125 \times 10^{-2} \text{ mole}$
	required 1 mole HCl. Mole fraction of $H_2$ in the gaseous	55.	In the reaction, $As_2S_5 + xHNO_3 \longrightarrow 5H_2SO_4 + yNO_2 +$
	mixture after the reaction is:		$2H_3AsO_4 + 12H_2$ , the values of x and y is:
	_	1	[J.E.E. (Orissa) 2006]
	(a) $\frac{1}{6}$		(a) 40,40
	(c) $\frac{1}{3}$	Ì	(c) $30,30$
47.	2 mole of H <sub>2</sub> S and 11.2 L of SO <sub>2</sub> at S.T.P. react according to		[Hint: $As_2S_5 + 40HNO_3 \longrightarrow 5H_2SO_4 + 40NO_2$
	following equation,		$+ 2H_3AsO_4 + 12H_2$
	$SO_2 + 2H_2S \longrightarrow 2H_2O + 3S$	30.	At T(K), 100 litres of dry oxygen is present in a sealed
	What will be the number of moles of sulphur formed in the		container. It is subjected to silent electric discharge, till the volumes of oxygen and ozone become equal. What is the
	reaction?		volumes of oxygen and ozone become equal. What is the volume in litres of ozone formed at $T(K)$ ?
	(a) 1.5		[E.A.M.C.E.T. (Engg.) 2006]
	(c) 11.2	1	(a) 50
48.	3.92 g of ferrous ammonium sulphate crystals are dissolved		(c) 30
	in 100 mL of water, 20 mL of this solution requires 18 mL of		[Hint: Let the volume of $O_2$ converted into ozone be = x litre
	potassium permanganate during titration for complete	,	Volume of ozone formed = $\frac{2x}{3}$ litre
	oxidation. The weight of KMnO <sub>4</sub> present in one litre of the		Volume of oxygen left behind = $(100 - x)$ litre
	solution is: [C.E.T. (Tamil Nadu) 2002]		•
	(a) 34.76 g		$\therefore \frac{2x}{3} = 100 - x$ $x = 60 \text{ litre}$
40	(c) 1.238 g		
49.	30 g of magnesium and 30 g of oxygen are reacted, then the residual mixture contains: [K.C.E.T. 2002]		Thus, ozone formed $\frac{2x}{3} = 40$ litre]
	(a) 60 g magnesium oxide only	57.	2 1 ,
	(b) 40 g magnesium oxide and 20 g of oxygen		density 1.84 g/mL is: [B.V.(Pune) 2006]
	(c) 45 g magnesium oxide and 15 g of oxygen		(a) 1.043 m
	(d) 50 g of magnesium oxide and 10 g of oxygen		(c) 10.43 m
50.			[Hint: Mass of solution = 1840 g
	moles of $H_2O_2$ required is : [A.I.I.M.S. 2004]		Mass of $H_2SO_4 = \frac{93}{100} \times 1000 = 930 \text{ g}$
	1		No. of moles = $\frac{930}{98}$
	(a) $\frac{1}{2}$		Mass of water = $1840 - 930 = 910 \text{ g}$
	(c) $\frac{5}{2}$ $\square$ (d) $\frac{7}{2}$ $\square$		
<i>-</i> 1	2	-	Molality = $\frac{930}{98} \times \frac{1000}{910} = 10.43 \text{ m}$
51.	One mole of magnesium nitride on reaction with excess of	58.	7
	water gives: [A.I.E.E.E. 2004]	(	with one mole of sulphite ion in acidic solution is:

	(a) 4/5	[	[Hint: $2KMnO_4 + 3H_2SO_4 + 5 \mid \longrightarrow K_2SO_4 + 2MnSO_4$
	(c) 1		2 mole COOH
	[Hint: $2MnO_4^- + 6H^+ + 5SO_3^{2-} \longrightarrow 2Mn^{2+} + 5SO_4^{2-} + 3H_2O$ ]		5 mole 8H <sub>2</sub> O + 10 CO <sub>2</sub>
59.	If equal volumes of 1M KMnO <sub>4</sub> and 1M K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> solutions		$0.5 \text{ L} \times 10^{-2} M = \frac{1}{2} \times \frac{1}{100} = \frac{1}{200} M$
	are allowed to oxidise Fe(II) to Fe(III) in acidic medium then	[	$\frac{0.5 \text{ L} \times 10^{-100} \text{ m} - 2}{2} \times \frac{100^{-200} \text{ m}}{2}$
	Fe(II) oxidised will be: [E.A.M.C.E.T. (Med.) 2007]		KMnO <sub>4</sub> reqd. = $\frac{2}{5} \times \frac{1}{200} = \frac{2}{1000} = \frac{20}{10000} = 20 \times 10^{-4} \text{ M}$
	(a) more by $KMnO_4$ $\Box$ (b) more by $K_2Cr_2O_7$ $\Box$	67.	250 mL of a Na <sub>2</sub> CO <sub>3</sub> solution contains 2.65 g of Na <sub>2</sub> CO <sub>3</sub> .
	(c) equal in both the cases	".	10 mL of this solution is added to $x$ mL of water to obtain
	(d) cannot be determined	ļ	$0.001 M \text{ Na}_2\text{CO}_3$ solution. The value of x is:
60.	A gas has a vapour density 11.2. The volume occupied by		(Mol. mass of $Na_2CO_3 = 106$ ) [B.H.U. 2008]
	1 g of the gas at NTP is: [P.M.T.(Pb.) 2005]	}	(a) 1000
	(a) 1L		(c) 9990
	(c) 22.4L		[Hint: 1000 mL of solution contains sodium carbonate
	[Hint: Mol. mass of the gas = $11.2 \times 2 = 22.4$ ]		$= 2.65 \times 4$
61.	The mass of carbon anode consumed (giving only carbon		= $10.60 \text{ g}$ , <i>i.e.</i> , the solution is $0.1 M$
	dioxide) in the production of 270 kg of aluminium metal from		$10 \times 0.1 = 0.001 \times V, i.e., V = 1000$
	bauxite by Hall process is: [C.B.S.E. (P.M.T.) 2005]		x = 1000 - 10 = 990
	(a) $270  \text{kg}$	68.	40 g of a sample of carbon on combustion left 10% of it
	(c) $90 \text{ kg}$ $\square$ (d) $180 \text{ kg}$ $\square$		unreacted. The volume of oxygen required at S.T.P. for this
	[Hint: $2A1_0O_0 + 3C \longrightarrow 4A1_0 + 3CO_0$ ]		combustion reaction is: [E.A.M.C.E.T. (Med.) 2008]
	[Hint: $2Al_2O_3 + 3C \longrightarrow 4Al + 3CO_2$ ] $(3 \times 12)g \longrightarrow (4 \times 27)g$		(a) 22.4L
62.	Sodium bicarbonate on heating decomposes to form sodium		(c) 11.2L
٠	carbonate, CO <sub>2</sub> and water. If 0.2 mole of sodium bicarbonate	69.	The value of 'n' in the reaction is:
	is completely decomposed, how many moles of sodium		$Cr_2O_7^{2-} + 14H^+ + nFe^{2+} \longrightarrow 2Cr^{3+} + nFe^{3+} + 7H_2O$
	carbonate is formed? [C.E.T. (J&K) 2006]		[P.E.T. (M.P.) 2008]
	(a) 0.1		(a) 2
	(c) 0.05		(c) 6
			[ <b>Hint</b> : $Cr_2O_7^{2-} + 14H^+ + 6Fe^{2+} + 6Fe^{3+} + 7H_2O$ ]
	[Hint: $2NaHCO_3 \longrightarrow Na_2CO_3 + H_2O + CO_2$ ]	70.	For the reaction,
63.	How many moles of lead (II) chloride will be formed from a	1	$Fe_2O_3 + 3CO \longrightarrow 2Fe + 3CO_2$
	reaction between 6.5 g of PbO and 3.2 g HCl? [C.B.S.E. 2008]		the volume of CO required to reduce one mole of Fe <sub>2</sub> O <sub>3</sub> is:
	(a) 0.011		[C.E.T. (Karnataka) 2008]
	(c) 0.044	1	(a) $67.2  \text{dm}^3$
	[ <b>Hint</b> : PbO + 2HCl $\longrightarrow$ PbCl <sub>2</sub> + H <sub>2</sub> O ]	1	(c) $22.4 \mathrm{dm}^3$ $\square$ (d) $44.8 \mathrm{dm}^3$ $\square$
	[Hint: PbO + 2HCl $\longrightarrow$ PbCl <sub>2</sub> + H <sub>2</sub> O ] $\xrightarrow{6.5}$ mole $\xrightarrow{3.2}$ mole	71.	
	[Hint: PbO + 2HCl $\longrightarrow$ PbCl <sub>2</sub> + H <sub>2</sub> O ] $\frac{6.5}{224}$ mole $\frac{3.2}{36.5}$ mole $= 0.029 = 0.087$	71.	The molarity of NaOH solution by dissolving 4g of it in
64.	$\frac{6.5}{224} \text{ mole} \qquad \frac{3.2}{36.5} \text{ mole} \\ = 0.029 \qquad = 0.087$	71.	The molarity of NaOH solution by dissolving 4g of it in 250 mL water is: [J.E.E. (W.B.) 2010]
64.	$\frac{6.5}{224} \text{ mole} \qquad \frac{3.2}{36.5} \text{ mole}$ $= 0.029 \qquad = 0.087$ The number of moles of oxygen is obtained by electrolytic	71.	The molarity of NaOH solution by dissolving 4g of it in 250 mL water is: [J.E.E. (W.B.) 2010]
64.	$\frac{6.5}{224} \text{ mole} \qquad \frac{3.2}{36.5} \text{ mole} \\ = 0.029 \qquad = 0.087$	71.	The molarity of NaOH solution by dissolving 4g of it in 250 mL water is : [J.E.E. (W.B.) 2010] (a) $0.4 \text{ M}$
64.	$\frac{6.5}{224} \text{ mole} \qquad \frac{3.2}{36.5} \text{ mole}$ $= 0.029 \qquad = 0.087$ The number of moles of oxygen is obtained by electrolytic decomposition of 108 g water is: [J.I.P.M.E.R. 2008]		The molarity of NaOH solution by dissolving 4g of it in 250 mL water is: [J.E.E. ### **Objective Questions for IIT ASPIRANTS**

1. What mass of Mg(OH)<sub>2</sub> is required to neutralize 125 mL of

0.136 M hydrochloric acid solution?

(Molar mass of Mg(OH)<sub>2</sub> =  $58.33 \text{ g mol}^{-1}$ )

(a) 0.248 g

(b) 0.496 g

(c) 0.992 g

(d) 1.98 g

[Hint:  $Mg(OH)_2 + 2HCl \longrightarrow MgCl_2 + 2H_2O$ 

Number of moles of HCl = 
$$\frac{MV}{1000} = \frac{0.136 \times 125}{1000}$$
  
= 0.017

- 2 mole HCl is neutralized by 58.33 g of Mg(OH)<sub>2</sub>
- 0.017 mole HCl will be neutralized by

$$\frac{58.33}{2}$$
 × 0.017 g Mg(OH)<sub>2</sub> = 0.496 g]

- 2. Calculate the mass of ammonia that can be produced from the decomposition of a sample of (NH<sub>4</sub>)<sub>2</sub>PtCl<sub>6</sub> containing 0.1 g Pt. Molar mass of  $(NH_4)_2$ PtCl<sub>6</sub> is 443.9 g mol<sup>-1</sup>.
  - (a) 0.0811 g

(b) 0.0766 g

(c) 0.0175 g

(d) 0.00766 g

Consider the following data

dei die following data .	•
Element	Atomic mas
$\boldsymbol{A}$	12.01
R	35.5

A and B combine to form a new substance 'X'. If 4 moles of B combines with 1 mole of A to give 1 mole of 'X' then mass of one mole of 'X' is:

(a) 154 g

(b) 74 g

(c) 47.5 g

(d) 166 g

[Hint:  $A + 4B \longrightarrow X$ 

Molar mass of  $X = 12.01 + 4 \times 35.5 = 154 \text{ g mol}^{-1}$ 

Chlorine can be prepared by reacting HCl with MnO<sub>2</sub>. The reaction is represented by this equation:

$$MnO_2(s) + 4HCl(aq.) \longrightarrow Cl_2(g) + MnCl_2(aq.) + 2H_2O(l)$$

Assuming the reaction goes to completion, what mass of concentrated HCl solution (36% HCl by mass) is needed to produce 2.5 g of Cl<sub>2</sub>?

(a) 5.15 g

(b) 14.3 g

- (d) 26.4 g
- 5. What volume of 3M Na<sub>2</sub>SO<sub>4</sub> must be added to 25 mL of 1 M BaCl<sub>2</sub> to produce 5 g BaSO<sub>4</sub>?
  - (a) 7.2 mL

(b) 8.3 mL

(c) 10 mL

(d) 14 mL

[Hint:  $Na_2SO_4 + BaCl_2 \longrightarrow BaSO_4 + 2NaCl$ 

Number of moles of BaSO<sub>4</sub> = 
$$\frac{\text{Mass}}{\text{Molar mass}}$$
  
=  $\frac{5}{233}$  = 0.0215

Number of moles of  $Na_2SO_4$  needed = 0.0215

$$\frac{MV}{1000} = 0.0215$$
$$\frac{3 \times V}{1000} = 0.0215$$
$$V = 7.2 \text{mL}$$

When FeCl<sub>3</sub> is ignited in an atmosphere of pure oxygen, this reaction takes place:

$$4\text{FeCl}_3(s) + 3\text{O}_2(g) \longrightarrow 2\text{Fe}_2\text{O}_3(s) + 6\text{Cl}_2(g)$$
  
If 3 moles of FeCl<sub>3</sub> are ignited in the presence of 2 moles of O<sub>2</sub> gas, how much of which reagent is present in excess and, therefore, remains unreacted?

- (a) 0.33 mole FeCl<sub>2</sub> remain unreacted
- (b) 0.67 mole FeCl<sub>3</sub> remain unreacted
- (c) 0.25 mole O<sub>2</sub> remain unreacted
- (d) 0.50 mole O<sub>2</sub> remain unreacted
- A self-contained breathing apparatus uses potassium superoxide, KO<sub>2</sub>, to convert the carbon dioxide and water in exhaled air into oxygen, as shown by the equation:

$$4KO_2(s) + 2H_2O(g) + 4CO_2(g) \longrightarrow 4KHCO_3(s) + 3O_2(g)$$
  
How many molecules of oxygen gas will be produced from the 0.0468 g of carbon dioxide that is exhaled in a typical breath?

- (a)  $4.8 \times 10^{20}$
- (b)  $6.4 \times 10^{20}$
- (c)  $8.5 \times 10^{20}$
- (d)  $1.9 \times 10^{21}$

[Hint: : 4 mole CO<sub>2</sub> gives 3 mole O<sub>2</sub>

$$\therefore \left(\frac{0.0468}{44}\right) \text{ mole CO}_2 \text{ will give } \frac{3}{4} \times \frac{0.0468}{44} \text{ mole O}_2$$
$$= 7.977 \times 10^{-4} \text{ mole}$$

Number of molecules of  $O_2 = 7.977 \times 10^{-4} \times 6.023 \times 10^{23}$ 

$$= 4.8 \times 10^{20} \, 1$$

Antimony reacts with chlorine according to this equation:

$$2Sb + 3Cl_2 \rightleftharpoons 2SbCl_3$$

How many grams of SbCl<sub>3</sub> can be prepared if 0.012 mole of antimony are reacted with 0.02 mole of chlorine? The molar mass of SbCl<sub>3</sub> equals  $228.2 \text{ g mol}^{-1}$ :

(a) 1.52 g

(b) 1.83 g

(c) 2.74 g

- (d) 4.56 g
- 9. A gaseous mixture of propane and butane of volume 3L on complete combustion produces 10 L of CO2 under standard conditions of temperature and pressure. The ratio of volumes of propane to butane is:
  - (a) 1:2

(b) 2:1

(c) 3:2

- (d) 3:1
- 10. What amount of silver will be obtained on thermal decomposition of 2.76 g of silver carbonate Ag<sub>2</sub>CO<sub>3</sub> (276 amu)?
  - (a) 2.16 g

(b) 0.216 g

(c) 216 g

- (d) 21.6 g
- 11.  $PH_3(g)$  decomposes on heating to produce phosphorous and hydrogen. The change in volume when 100 mL of such gas is decomposed:
  - (a)  $+50 \,\text{mL}$
- (b)  $+500 \,\text{mL}$
- (c)  $-50 \, \text{mL}$
- (d)  $-500 \,\mathrm{mL}$

[Hint:  $4PH_3(g) \xrightarrow{Heat} P_4(s) + 6H_2(g)$ 

Volume of H<sub>2</sub> formed by decomposition of 100 mL PH<sub>3</sub>

$$=\frac{6}{4} \times 100 = 150 \text{ m}$$

 $= \frac{6}{4} \times 100 = 150 \text{ mL}$ Thus, change in volume = (150 - 100) = 50 mL]

- 12. What amount of BaSO<sub>4</sub> can be obtained on mixing 0.5 mole BaCl<sub>2</sub> with 1 mole of H<sub>2</sub>SO<sub>4</sub>?
  - (a) 0.5 mole
- (b) 0.15 mole
- (c) 0.1 mole
- (d) 0.2 mole

[Hint:  $BaCl_2 + H_2SO_4 \longrightarrow BaSO_4 + 2HCl$ Initially 0.5 1 0 0 0.5  $2 \times 0.51$ After reaction 0 (1 - 0.5)

13. In the reaction,

 $CrO_5 + H_2SO_4 \longrightarrow Cr_2(SO_4)_3 + H_2O + O_2$ one mole of  $CrO_5$  will liberate how many moles of  $O_2$ ?

(a) 5/2

(b) 5/4

- (d) none of these
- 14. Calcium carbonate decomposes on heating according to the equation:

$$CaCO_3(s) \longrightarrow CaO(s) + CO_2(g)$$

At S.T.P. the volume of CO<sub>2</sub> obtained by thermal decomposition of 50 g of CaCO<sub>3</sub> will be:

- (a) 22.4 litre
- (b) 44 litre
- (c) 11.2 litre
- (d) 1 litre
- 15. The volume in litres of CO<sub>2</sub> liberated at S.T.P. when 10 g of 90% pure limestone is heated completely, is:
  - (a) 22.4L

- (b) 2.24L
- (c) 20.16L
- (d) 2.016L

$$[ \text{Hint} : CaCO_3 \longrightarrow CaO + CO_2(g) \\ \text{$\stackrel{1 \text{ mole}}{(100 \text{ g})}$} \qquad \qquad \begin{array}{c} 22.4 \text{ lirre} \\ \text{at S.T.P.} \end{array}$$

$$\therefore$$
 100 g CaCO<sub>3</sub> = 22.4 L CO<sub>2</sub> at S.T.P.

∴ 9 g CaCO<sub>3</sub> 
$$\equiv \frac{22.4}{100} \times 9$$
 L at S.T.P.  
= 2.016 L CO<sub>2</sub> at S.T.P. ]

16. A metal oxide has a formula  $Z_2O_3$ . It can be reduced by hydrogen to give free metal and water. 0.1596 g of the metal requires 6 mg of hydrogen for complete reduction. The atomic mass of the metal is:

(a) 27.9

(b) 159.6

(c) 79.8

(d) 55.8

[Hint: 
$$Z_2O_3 + 3H_2(g) \longrightarrow 2Z + 3H_2O$$

∴ 6 g H<sub>2</sub> gives 2 mole Z

 $\therefore$  6 × 10<sup>-3</sup> g H<sub>2</sub> will give 0.002 mole Z

Number of moles = 
$$\frac{\text{Mass}}{\text{Molar mass}}$$
  

$$0.002 = \frac{0.1596}{\text{Molar mass}}$$

: Molar mass = 
$$\frac{0.1596}{0.002}$$
 = 79.8 g mol<sup>-1</sup>]

17. Chlorine gas can be produced by reacting sulphuric acid with a mixture of MnO2 and NaCl. The reaction follows the equation.

$$2NaCl + MnO_2 + 3H_2SO_4 \longrightarrow 2NaHSO_4 + MnSO_4$$

---+Cl<sub>2</sub>+2H<sub>2</sub>O

what volume of chlorine can be produced from 1 g of sodium chloride under standard conditions of temperature and pressure?

- (a) 1.915 L
- (b) 19.15 L
- (c) 20.22L
- (d) 0.191 L

[Hint: 2 mole NaCl (117 g)  $\equiv$  1 mole Cl<sub>2</sub> (22.4 L at S.T.P.)

∴ 1 g NaCl will give 
$$\frac{22.4}{117}$$
 L Cl<sub>2</sub> at S.T.P.  
= 0.191 L Cl<sub>2</sub> at S.T.P.

18. 1 mole of a gaseous aliphatic compound,  $C_nH_{3n}O_m$  is completely burnt in an excess of oxygen. The contraction in volume is:

- (a)  $\left(1 + \frac{1}{2}n \frac{3}{4}m\right)$  (b)  $\left(1 + \frac{3}{4}n \frac{1}{4}m\right)$  (c)  $\left(1 \frac{1}{2}n \frac{3}{4}m\right)$  (d)  $\left(1 + \frac{3}{4}n \frac{1}{2}m\right)$

- 19. A mixture of CH<sub>4</sub> and C<sub>2</sub>H<sub>4</sub> was completely burnt in an excess of oxygen, yielding equal volumes of CO<sub>2</sub> and steam. Calculate the percentages of the compounds in the original mixture:
  - (a) 25 % CH<sub>4</sub> and 75% C<sub>2</sub>H<sub>4</sub> (b) 30% CH<sub>4</sub> and 70% C<sub>2</sub>H<sub>4</sub>
  - (c) 75% CH<sub>4</sub> and 25% C<sub>2</sub>H<sub>4</sub> (d) 50% CH<sub>4</sub> and 50% C<sub>2</sub>H<sub>4</sub>

Following questions have more than one correct answer:

- 20. 1.5 g of oxygen is produced by heating KClO<sub>3</sub>. How much KCl is produced in the reaction?
  - (a)  $4.15 \times 10^{-2}$  mole (c)  $1.78 \times 10^{-2}$  mole
- (b) 4.33 g
- (d) 1.33 g
- 21. Calculate the amount of lime that can be produced by heating 100 g of 90% pure limestone:
  - (a) 50.4 g

- (b) 0.98 mole
- (c) 0.9 mole

[Hint: 
$$CaCO_3 \longrightarrow CaO + CO_2$$
  
 $100 \text{ g}$   $56 \text{ g}$   
 $100 \text{ g } CaCO_3 \equiv 56 \text{ g } CaO$ 

:. 90 g CaCO<sub>3</sub> = 
$$\frac{56}{100} \times 90$$
 g CaO, *i.e.*, 50.4 g CaO

Number of moles of CaO = 
$$\frac{50.4}{56}$$
 = 0.9 ]

- 22. In an experiment, following four gases were produced. 11.2 L of which two gases at S.T.P. will weigh 14 g?
  - (a) N<sub>2</sub>O

· (b) NO<sub>2</sub>

(c)  $N_2$ 

- (d) CO
- 23. 2 mole of CO<sub>2</sub> is required to prepare:
  - (a) 336 g of NaHCO<sub>3</sub>
- (b) 168 g of NaHCO<sub>3</sub>
- (c) 462 g of Ca(HCO<sub>3</sub>)<sub>2</sub>
- (d) 162 g of Ca(HCO<sub>3</sub>)<sub>2</sub>
- 24. 8.7 g of pure MnO<sub>2</sub> is heated with an excess of HCl and gas evolved is passed into a solution of KI. Calculate the amount of the iodine liberated:

(Mn = 55, Cl = 35.5, I = 127)

- (a) 0.1 mole
- (b) 25.4 g

(c) 15.4 g

(d) 7.7 g

1. (b) 2. (c) 3. (a) 4. (b) 5. (a) **6.** (a) 7. (a) 8. (c) 9. (b) 10. (a) 11. (a) 12. (a) 13. (d) 14. (c) 15. (d) **16.** (c) 17. (d) 18. (d) 19. (d) 20. (c, d)

# YPE QUESTIONS

#### **THOUGHT 1**

In a reaction vessel 100 g H<sub>2</sub> and 100 g Cl<sub>2</sub> are mixed and suitable conditions are provided for the following reaction,

$$H_2(g) + Cl_2(g) \xrightarrow{?} 2HCl(g)$$

Quantum yield of this reaction is,  $\phi = 10^5$ .

- 1. Select the correct statement(s) for the above reaction:
  - (a) Presence of light is required for this reaction
  - (b) It is a chain reaction
  - (c) Catalyst is required
  - (d) All of the above
- 2. The limiting reagent in this reaction will be:
  - (a)  $H_2$

(b) Cl<sub>2</sub>

- (d) cannot be predicted
- 3. The actual amount of HCl formed in this reaction is:
  - (a) 102.8 g
- (b) 73 g

- (c) 36.5 g
- (d) 142 g
- 4. The amount of excess reactant remaining:
  - (a) 50 g

(b) 97.2 g

(c) 46 g

- (d) 64 g
- 5. The amount of HCl formed (at 90% yield) will be:
  - (a) 36.8 g
- (b) 62.5 g

(c) 80 g

(d) 92.53 g

#### **THOUGHT 2**

Dissolved oxygen in water is determined by using a redox reaction. Following equations describe the procedure:

- $2\text{Mn}^{2+}(aq.) + 4\text{OH}^{-}(aq.) + \text{O}_{2}(g) \longrightarrow 2\text{MnO}_{2}(s) + 2\text{H}_{2}\text{O}(l)$ I.
- II.  $MnO_2(s) + 2I^-(aq.) + 4H^+(aq.) \longrightarrow Mn^{2+}(aq.) +$

 $I_2(aq.) + 2H_2O(l)$ 

 $2S_2O_3^{2-}(aq.) + I_2(aq.) \longrightarrow S_4O_6^{2-}(aq.) + 2I^{-}(aq.)$ Ш.

- 1. How many moles of  $S_2O_3^{2-}$  are equivalent of each mole of  $O_2$ ?
  - (a) 0.5

(c) 2

- (d) 4
- 2. What amount of I<sub>2</sub> will be liberated from 8 g dissolved oxygen?
  - (a) 127 g

(b) 254 g

(c) 504 g

- (d) 1008 g 3. If  $3 \times 10^{-3}$  mole O<sub>2</sub> is dissolved per litre of water then what will be the molarity of I produced in the given reaction?
  - (a)  $3 \times 10^{-3} M$
- (b)  $4 \times 3 \times 10^{-3} M$
- (c)  $2 \times 3 \times 10^{-3} M$
- (d)  $(1/2) \times 3 \times 10^{-3} M$
- Number of which two chemical species will be same in the given procedure?
  - (a) MnO<sub>2</sub>
- (b)  $I_2$

(c) I

- (d)  $S_2O_3^{2-}$
- 8 mg dissolved oxygen will consume ........ (a)  $5 \times 10^{-4}$  mole Mn<sup>2+</sup>
  - (b)  $2.5 \times 10^{-4}$  mole Mn<sup>2+</sup>
  - (c)  $10^{-3}$  mole Mn<sup>2+</sup>
- (d) 2 mole Mn<sup>2+</sup>

- Thought 1 2. (b) 3. (a) 1. (a, b)
- Thought 2 1. (d)
- 2. (a)
- 3. (b)
- 4. (b)
- 4. (a)
- 5. (d) 5. (a)

### INTEGER ANSWER Type Questions

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. The volume of oxygen required for the complete burning of 4 ml of methane at NTP is:
- 2. How much residue is left after strongly heating 1.28 g of silver carbonate?
- 3. The mass of marble required for the preparation of 2.8 g of quick lime by strong heating is:
- 4. 9.5 g of Mg is burnt in a closed vessel containing 5g of O<sub>2</sub>.
  The mass of excess reagent is:
- 5. The amount of ammonium nitrate that should be decomposed for getting 2.24 litre nitrous oxide is:
- 6. Potassium permanganate in presence of dilute H<sub>2</sub>SO<sub>4</sub> reacts with oxalic acid (anhydrous). Write the balanced equation of the reaction and find out how many moles of oxalic acid are oxidised by 2 moles of KMnO<sub>4</sub>?

### Auswers

1. (8) 
$$CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O$$
1 vol. 2 vol. 8 rd.

2. (1) 
$$Ag_2CO_3 \longrightarrow 2Ag + CO_2 + \frac{1}{2}O_2$$

3. (5) 
$$CaCO_3 \longrightarrow CaO_{56 g} + CO_2$$

4. (2) 
$$2Mg + O_2 \longrightarrow 2MgO$$
;

5g O<sub>2</sub> reacts with 
$$=\frac{48}{32}\times5=7.5$$
 g Mg

5. (8) 
$$NH_4NO_3 \longrightarrow N_2O$$
80 g 22.4 litre

**6.** (5) 
$$2KMnO_4 + 3H_2SO_4 + 5H_2C_2O_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 10CO_2$$

### 17.1 INTRODUCTION

Many chemical reactions in nature, particularly in living systems, occur in aqueous solutions. Reactions are often carried out in the laboratory in aqueous solutions because these are generally more rapid in solution than when pure solid reactants are mixed. A quantitative analysis is one in which the amount or concentration of a particular species in a sample is determined accurately and precisely.

Volumetric analysis is a quantitative analysis. It involves the measurement of the volume of a known solution required to bring about the completion of the reaction with a measured volume of the unknown solution. The reaction used in volumetric analysis must fulfill the following conditions:

- (i) The chemistry of the reaction should be known and it should be represented by a definite chemical equation.
- (ii) The reaction should be instantaneous and proceed to completion over a fairly wide range of concentrations.
- (iii) There must be means to know the exact state of its completion.

The process of addition of the known solution from the burette to the measured volume of solution of the substance to be estimated until the reaction between the two is just complete, is termed as titration. Thus, a titration involves two solutions:

- (i) Unknown solution: The solution consisting the substance to be estimated is termed unknown solution. The substance is termed titrate.
- (ii) Standard solution: The solution in which an accurately known amount of the reagent (titrant) has been dissolved in a known volume of the solution is termed standard solution. There are two types of reagents (titrants):
- (a) **Primary standards:** These can be accurately weighed and their solutions are not to be standardised before use. Oxalic acid ( $H_2C_2O_4$ · $2H_2O$ ), potassium dichromate ( $K_2Cr_2O_7$ ), silver nitrate (AgNO<sub>3</sub>), copper sulphate (CuSO<sub>4</sub>· $5H_2O$ ), ferrous ammonium sulphate [FeSO<sub>4</sub>(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>· $6H_2O$ ], sodium thiosulphate (Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>· $5H_2O$ ), etc., are the examples of primary standards.
- (b) Secondary standards: The solutions of these reagents are to be standardised before use as these cannot be weighed accurately. The examples are sodium hydroxide (NaOH), potassium hydroxide (KOH), hydrochloric acid (HCl), sulphuric acid (H<sub>2</sub>SO<sub>4</sub>), potassium permanganate (KMnO<sub>4</sub>), iodine, etc.

Law of equivalence: It is applied in all volumetric estimations. According to it, the chemical substances react in the ratio of their chemical equivalent masses.

or  $\frac{\text{Mass of substance } A}{\text{Chemical equivalent mass of } A}$ 

 $= \frac{\text{Mass of substance } B}{\text{Chemical equivalent mass of } B}$ 

or gram equivalent of A = gram equivalent of B or milli-gram equivalent of A = milli-gram equivalent of B

The point at which the amounts of the two reactants are just equivalent is known as **equivalence point** or **end point**. An auxiliary substance which helps in the usual detection of the completion of the titration or equivalence point or end point is termed as **indicator**, *i.e.*, substances which undergo some easily detectable changes at the equivalence point are used as indicators.

## 17.2 METHODS OF EXPRESSING CONCENTRATIONS OF SOLUTIONS

The concentration of a solution can be expressed in various ways:

1. Per cent by mass: The percentage by mass of a solute in a solution is 100 times the mass of the solute divided by the total mass of the solution.

$$\%$$
 Solute =  $\frac{\text{Mass of solutein grams}}{\text{Mass of solutionin grams}} \times 100$ 

Thus, 10% solution of sodium chloride means 10 grams of sodium chloride is present in 100 grams of the solution, *i.e.*, 10 grams of sodium chloride has been dissolved in 90 grams of water.

2. Molarity (Molar concentration): It is a common method for expressing the concentration of solution. It is defined as the number of moles of the solute per litre of the solution.

Molarity = Number of moles of solute

Number of millimoles of the solute

or Molarity = Number of milli - moles of the solute

Number of milli - litres of the solution

or Molarity × Number of litres of solution

or

= Number of moles of solute

or Molarity × Number of milli-litres of solution

= Number of milli-moles of solute

When a solution is diluted by adding more of the solvent, the number of moles does not change. The volume of solution and its concentration do change. Let the initial molarity and volume be  $M_1$  and  $V_1$  and the molarity and volume after dilution be  $M_2$  and  $V_2$  respectively.

 $V_1 \times M_1$  = Number of moles of solute =  $V_2 \times M_2$  $V_1 M_1 = V_2 M_2$  (Molarity equation)

Let w grams of the solute of molecular mass M be dissolved in V litres of solution.

Molarity of the solution = 
$$\frac{w}{M \times V}$$

$$\left[\frac{w}{M}\right]$$
 = No. of gram moles of the solute

or Molarity  $\times M = \frac{w}{V} =$  Strength of the solution where M is molecular mass of solute.

Thus, strength of the solution (g/L) (i.e., No. of grams of the solute per litre)

= Molarity × Molecular mass

Solutions are generally expressed as 1M, 2M, M/2, M/10, M/100, M/1000, etc.

1M = Molar solution = 1 gram mole of the solute per litre of solution

M/2 = Semi-molar solution = 1/2 gram mole of the solute per litre of solution

M/10 = Deci-molar solution = 1/10 gram mole of the solute per litre of solution

M/100 = Centi-molar solution = 1/100 gram mole of the solute per litre of solution

M/1000 = Milli-molar solution = 1/1000 gram mole of the solute per litre of solution

3. Molality: It is defined as the number of gram moles of the solute present in 1 kg of the solvent.

$$Molality = \frac{Number of gram moles of the solute}{Number of kilograms of the solvent}$$

Let w grams of the solute of molecular mass M be present in W grams of the solvent

Molality = 
$$\frac{w/M}{W/1000}$$
 =  $\frac{w}{M \times W} \times 1000$ 

If the density of the solution is known, then molality can be converted into molarity and *vice-versa*.

**4. Mole fraction:** This method is used when the solution is constituted by the use of two or more components. The mole fraction of a substance is defined as the number of moles of the substance divided by the total number of moles of the solution. Taking three components A, B and C,

Components	$\boldsymbol{A}$	В	C
Mass (grams)	$w_1$	$w_2$	$w_3$
Molecular mass	$m_1$	$m_2$	<i>m</i> <sub>3</sub>
No. of gram moles	$\frac{w_1}{m_1}$	$\frac{w_2}{m_2}$	$\frac{w_3}{m_3}$

Total number of gram moles 
$$=\frac{w_1}{m_1} + \frac{w_2}{m_2} + \frac{w_3}{m_3}$$

Mole fraction of  $A$ ,  $(f_1) = \frac{\frac{w_1}{m_1}}{\frac{w_1}{m_1} + \frac{w_2}{m_2} + \frac{w_3}{m_3}}$ 

Mole fraction of  $B$ ,  $(f_2) = \frac{\frac{w_2}{m_2}}{\frac{w_1}{m_1} + \frac{w_2}{m_2} + \frac{w_3}{m_3}}$ 

Mole fraction of C, 
$$(f_3) = \frac{\frac{w_3}{m_3}}{\frac{w_1}{m_1} + \frac{w_2}{m_2} + \frac{w_3}{m_3}}$$

The sum of mole fraction of a solution is equal to 1, i.e.,

$$f_1 + f_2 + f_3 = 1$$

5. Normality: It is defined as the number of gram equivalents of the solute present in one litre of the solution.

Normality =  $\frac{\text{Number of gram equivalents of the solute}}{\text{Number of litres of the solution}}$ 

or Normality =  $\frac{\text{Number of mg equivalents of the solute}}{\text{Number of mL of the solution}}$ 

or Normality × Number of litres of solution

= Number of gram equivalents of the solute

Let w grams of the solute having equivalent mass E be present in V litres of the solution.

Normality = 
$$\frac{w/E}{V} = \frac{w}{E \times V}$$
  
Normality  $\times E = \frac{w}{V}$ 

or Normality  $\times E = \frac{\pi}{V}$ 

Normality × Equivalent mass of the solute = Strength of the solution (g/L)

Solutions are expressed as 1 N, 2 N, 0.5 N, 0.1 N, 0.01 N,

0.001 N, etc. 1N = Normal = One gram equivalent of the solute per

litre of solution 0.5N = Semi-normal = Half gram equivalent of the solute

per litre of solution 0.1N = Deci-normal = 1/10 gram equivalent of the solute

per litre of solution 0.01N = Centi-normal = 1/100 gram equivalent of the

solute per litre of solution

0.001N = Milli-normal = 1/1000 gram equivalent of the solute per litre of solution

**Normality equation:** Let there be two solutions of substances A and B and  $V_1$  mL of solution A be chemically equivalent to  $V_2$  mL of solution B. Let the equivalent mass of A and B be  $E_1$  and  $E_2$  respectively. Let the normalities and strengths (g/L) of these solutions be  $N_1$ ,  $S_1$  and  $N_2$ ,  $S_2$  respectively.

 $V_1$  mL of the solution will contain substance A

$$=\frac{S_1}{1000}\times V_1\,\mathrm{g}$$

 $V_1$  mL of the solution will contain number of g equivalents of substance A

$$=\frac{S_1\times V_1}{1000\times E_1}$$

Similarly,  $V_2$  mL of the solution will contain number of g equivalents of substance B

$$=\frac{S_2 \times V_2}{1000 \times E_2}$$

At equivalence point, these two will be equal,

So, 
$$\frac{S_1 \times V_1}{1000 \times E_1} = \frac{S_2 \times V_2}{1000 \times E_2}$$
or 
$$\frac{S_1}{E_1} \times V_1 = \frac{S_2}{E_2} \times V_2$$

We know that  $\frac{\text{Strength}}{\text{Equivalent mass}} = \text{Normality}$ 

So, 
$$N_1V_1 = N_2V_2$$
 (Normality equation)

Relationship between normality and molarity: We know that.

Strength of the solution (g/L) = Normality × Equivalent mass Similarly,

Strength of the solution (g/L) = Molarity × Molecular mass

So, 
$$\frac{\text{Normality}}{\text{Molarity}} = \frac{\text{Molecular mass of the substance}}{\text{Equivalent mass of the substance}} = n$$

or Normality = 
$$n \times$$
 Molarity

In the case of acids, 'n' is basicity of acids while in the case of bases, 'n' is acidity of bases.

Acid	Basicity	Base	Acidity
HC1	1	NaOH	1
HNO <sub>3</sub>	1	КОН	1
$H_2C_2O_4\cdot 2H_2O$	2	Ba(OH) <sub>2</sub>	2
$H_2SO_4$	2	Ca(OH) <sub>2</sub>	2
H <sub>3</sub> PO <sub>4</sub>	3	Al(OH) <sub>3</sub>	3.

### 17.3 TYPES OF TITRATIONS

Titrations can be classified as:

- 1. Acid-base titrations or acidimetry and alkalimetry
- 2. Oxidation-reduction titrations or redox titrations
- 3. Precipitation titrations
- 4. Complexometric titrations.

#### (1) Acid-base Titrations

When the strength of an acid is determined with the help of a standard solution of base, it is known as **acidimetry**. Similarly, when the strength of a base (alkali) is determined with the help of a standard solution of an acid, it is known as **alkalimetry**. Both these titrations involve neutralisation of an acid with an alkali. In these titrations H<sup>+</sup> ions of the acid combine with OH<sup>-</sup> ions of the alkali to form unionised molecules of water.

$$\begin{array}{ccc} & HA + BOH \longrightarrow BA + H_2O \\ & Acid & Alkali & Salt & Water \end{array}$$
 or 
$$\begin{array}{ccc} & H^+ + A^- + B^+ + OH^- \longrightarrow B^+ + A^- + H_2O \\ & & & H^+ + OH^- \longrightarrow H_2O \end{array}$$

The end point in these titrations is determined by the use of organic dyes which are either weak acids or weak bases. These change their colours within a limited range of hydrogen ion concentrations, *i.e.*, pH of the solution. Phenolphthalein is

a suitable indicator in the titrations of strong alkalies (free from carbonate) against strong acids or weak acids. Methyl orange is used as an indicator in the titrations of strong acids against strong and weak alkalies. As no indicator gives correct results in the titrations of weak acids against weak bases, such titrations are performed by some other methods (physical methods).

#### (2) Oxidation-reduction Titrations

The titrations based on oxidation-reduction reactions are called **redox titrations**. The chemical reactions proceed with transfer of electrons (simultaneous loss or gain of electrons) among the reacting ions in aqueous solutions. Sometimes these titrations are named after the reagent used, as:

(i) Permanganate titrations: These are titrations in which potassium permanganate is used as an oxidising agent in acidic medium. The medium is maintained by the use of dilute sulphuric acid. Potassium permanganate acts as a self-indicator. The potential equation, when potassium permanganate acts as an oxidising agent, is:

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$
  
or  $MnO_4^- + 8H^+ + 5e \longrightarrow Mn^{2+} + 4H_2O$ 

Before the end point, the solution remains colourless (when KMnO<sub>4</sub> solution is taken in burette) but after the equivalence point one extra drop of KMnO<sub>4</sub> solution imparts pink colour, *i.e.*, appearance of pink colour indicates the end point. Potassium permanganate is used for the estimation of ferrous salts, oxalic acid, oxalates, hydrogen peroxide, etc. The solution of potassium permanganate is always first standardised before its use.

(ii) Dichromate titrations: These are titrations in which, potassium dichromate is used as an oxidising agent in acidic medium. The medium is maintained acidic by the use of dilute sulphuric acid. The potential equation is:

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$
  
or  $Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 2Cr_3^{3+} + 7H_2O$ 

The solution of potassium dichromate can be directly used for titrations. It is mainly used for the estimation of ferrous salts and iodides. In the titration of  $K_2Cr_2O_7$  versus ferrous salt either an external indicator (potassium ferricyanide) or an internal indicator (diphenyl amine) can be used.

(iii) Iodimetric and iodometric titrations: The reduction of free iodine to iodide ions and oxidation of iodide ions to free iodine occurs in these titrations.

$$I_2 + 2e \longrightarrow 2I^-$$
 (reduction)  
 $2I^- \longrightarrow I_2 + 2e$  (oxidation)

These are divided into two types:

(a) Iodimetric titrations: These are the titrations in which free iodine is used. As it is difficult to prepare the solution of iodine (volatile and less soluble in water), it is dissolved in potassium iodide solution.

$$KI + I_2 \longrightarrow KI_3$$
Potassium tri-iodide

This solution is first standardised before use. With the standard solution of  $I_2$ , substances such as sulphite, thiosulphate, arsenite, etc., are estimated.

(b) Iodometric titrations: In iodometric titrations, an oxidising agent is allowed to react in neutral medium or in acidic medium, with excess of potassium iodide to liberate free iodine.

$$KI + Oxidising agent \longrightarrow I_2$$

Free iodine is titrated against a standard reducing agent usually with sodium thiosulphate. Halogens, oxyhalogens, dichromates, cupric ion, peroxides, etc., can be estimated by this method.

$$I_2 + 2Na_2S_2O_3 \longrightarrow 2NaI + Na_2S_4O_6$$

$$2CuSO_4 + 4KI \longrightarrow Cu_2I_2 + 2K_2SO_4 + I_2$$

$$K_2Cr_2O_7 + 6KI + 7H_2SO_4 \rightarrow Cr_2(SO_4)_3 + 4K_2SO_4 + 7H_2O + 3I_2$$

In iodimetric and iodometric titrations, starch solution is used as an indicator. Starch solution gives blue or violet colour with free iodine. At the end point the blue or violet colour disappears when iodine is completely changed to iodide.

#### (3) Precipitation Titrations

The titrations which are based on the formation of insoluble precipitates, when the solutions of two reacting substances are brought in contact with each other, are called **precipitation titrations.** For example, when a solution of silver nitrate is added to a solution of sodium chloride or a solution of ammonium thiocyanate, a white precipitate of silver chloride or silver thiocyanate is formed.

$$AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$$
  
 $AgNO_3 + NH_4CNS \longrightarrow AgCNS + NH_4NO_3$ 

Such titrations involving silver nitrate are called **argento**metric titrations.

#### (4) Complexometric Titrations

A titration, in which an undissociated complex is formed at the equivalence point, is called **complexometric titration**. These titrations are superior to precipitation titrations as there is no error due to co-precipitation.

$$Hg^{2+} + 2SCN^{-} \longrightarrow Hg(SCN)_{2}$$
  
 $Ag^{+} + 2CN^{-} \longrightarrow [Ag(CN)_{2}]^{-}$ 

EDTA (ethylenediaminetetraacetic acid) is a useful reagent which forms complexes with metals. In the form of disodium salt, it is used to estimate Ca<sup>2+</sup> and Mg<sup>2+</sup> ions in presence of erichrome black-T as an indicator.

# 17.4 DETERMINATION OF EQUIVALENT MASS

Equivalent mass is defined as the number of parts by mass, a chemical species combined with or displaced by 1.008 parts of hydrogen, 8 parts of oxygen or 35.5 parts of chlorine. Equivalent mass is not a constant number. It may change from reaction to reaction especially in the case of redox reactions.

(i) Equivalent mass of an acid: Equivalent mass of an acid is defined as the number of parts by mass of it which contains 1.008 parts by mass of replaceable hydrogen or it is the quantity of the acid by mass that supplies one mole of H<sup>+</sup> ions.

Eq. mass of acid = 
$$\frac{\text{Molecular mass of the acid}}{\text{Number of replaceable H atoms}}$$
  
=  $\frac{\text{Molecular mass of the acid}}{\text{Basicity of the acid}}$ 

Basicity of an acid is equal to number of replaceable hydrogen atoms present in one molecule of the acid.

Acid	Basicity	Mol. mass	Eq. mass
HCl	1	36.5	$\frac{36.5}{1}$ = 36.5
HNO <sub>3</sub>	1	63	$\frac{63}{1} = 63.0$
H <sub>2</sub> SO <sub>4</sub>	2	98	$\frac{98}{2} = 49.0$
СН₃СООН	. 1	60	$\frac{60}{1} = 60.0$
$H_2C_2O_4 \cdot 2H_2O$	2	126	$\frac{126}{2} = 63.0$
$H_3PO_4$	3	98	$\frac{98}{3} = 32.7$
$H_3PO_3$	2	82	$\frac{82}{2} = 41.0$
H <sub>3</sub> PO <sub>2</sub>	1	66	$\frac{66}{1} = 66.0$

(ii) Equivalent mass of a base: Equivalent mass of a base is the quantity of the base by mass that completely reacts with one gram equivalent of an acid. For example,

CaO + 2HCl 
$$\longrightarrow$$
 CaCl<sub>2</sub> + H<sub>2</sub>O  
56 2 × 36.5  
2 g equivalent

Hence, equivalent mass of CaO =  $\frac{56}{2}$  = 28.0

Eq. mass of a base =  $\frac{\text{Molecular mass of the base}}{\text{Acidity of the base}}$ 

Acidity of an alkali is the number of replaceable OHT ions present in one molecule of the base.

Alkali	Acidity	Mol. mass	Eq. mass
NaOH	. 1	40	$\frac{40}{1} = 40$
КОН	1 .	56	$\frac{56}{1}$ = 56
Ca(OH) <sub>2</sub>	2	74	$\frac{74}{2} = 37$
NH <sub>4</sub> OH	1	35	$\frac{35}{1}$ = 35

(iii) Equivalent mass of a salt: It is defined as that mass of the salt which reacts with one gram equivalent of an acid or a base or some other salt. For example,

(a) 
$$Na_2CO_3$$
 +  $2HC1 \longrightarrow 2NaC1 + CO_2 + H_2O$   
1 mole 2 g equivalent

Eq. mass of sodium carbonate =  $\frac{\text{Mol. mass of Na}_2\text{CO}_3}{2}$ 

(b) 
$$\underset{1 \text{ mole}}{\text{AgNO}_3} + \underset{1 \text{ g equivalent}}{\text{HCl}} \rightarrow \underset{1 \text{ AgCl}}{\text{AgCl}} + \underset{1 \text{ HNO}_3}{\text{HNO}_3}$$

Eq. mass of AgNO<sub>3</sub> = 
$$\frac{\text{Mol. mass of AgNO}_3}{1}$$

(c) 
$$NH_4Cl$$
 +  $NaOH \longrightarrow NH_3 + NaCl + H_2O$   
1 mole 1 g equivalent

Eq. mass of 
$$NH_4Cl = \frac{Mol. \text{ mass of } NH_4Cl}{1}$$

$$\begin{array}{cccc} (d) & BaCl_2 & + & Na_2CO_3 \longrightarrow BaCO_3 + 2NaCl \\ \hline & 1 & mole & 2 & g & equivalent \\ \end{array}$$

Eq. mass of BaCl<sub>2</sub> = 
$$\frac{\text{Mol. mass of BaCl}_2}{2}$$

Alternatively, Eq. mass of the salt

= Mol. mass of the salt

Total no. of positive or negative valencies of the radicals

Eq. mass of 
$$CaCO_3 = \frac{100}{2} = 50$$

(iv) Equivalent mass of an oxidising agent:

(a) Available oxygen concept: It is the mass of an oxidising agent which provides 8 grams of oxygen for oxidation. For example,

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$
  
294.2 g 3 × 16  
= 48 g

Eq. mass of 
$$K_2Cr_2O_7 = \frac{294.2}{48} \times 8 = \frac{294.2}{6} = 49.04$$

Potassium permanganate acts as an oxidising agent in acidic, alkaline and neutral mediums.

#### Acidic medium:

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$
 $5 \times 16$ 
 $= 80 \text{ g}$ 

Eq. mass of KMnO<sub>4</sub> = 
$$\frac{2 \times 158 \times 8}{80} = \frac{158}{5} = 31.6$$

#### Alkaline medium:

$$2KMnO_4 + 2KOH \longrightarrow K_2MnO_4 + 3H_2O + [O]$$

$$2 \times 158 \text{ g}$$

$$2 \times 8 = 16 \text{ g}$$

Eq. mass of KMnO<sub>4</sub> = 
$$\frac{2 \times 158}{16} \times 8 = 158$$

#### Neutral medium:

$$2KMnO4 + H2O \longrightarrow 2MnO2 + 2KOH + 3[O]$$

$$2 \times 158 g$$

$$3 \times 16 = 48$$

Eq. mass of KMnO<sub>4</sub> = 
$$\frac{2 \times 158}{48} \times 8 = \frac{158}{3} = 52.67$$

(b) Electron concept: The equivalent mass of an oxidising agent is the molecular mass of the oxidising agent divided by the number of electrons gained by one mole of the oxidising agent:

Eq. mass of an oxidising agent

$$= \frac{\text{Molecular mass}}{\text{No. of electrons gained by 1 mole}}$$

#### **Examples:**

(i) Acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>:

$$Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 2Cr^{3+} + 7H_2O$$
  
Eq. mass of  $K_2Cr_2O_7 = \frac{\text{Molecular mass}}{6}$   
 $= \frac{294.2}{6} = 49.03$ 

(ii) Acidified KMnO<sub>4</sub>:

$$MnO_4^- + 8H^+ + 5e \longrightarrow Mn^{2+} + 4H_2O$$
Eq. mass of KMnO<sub>4</sub> = 
$$\frac{Molecular mass}{5}$$
= 
$$\frac{158}{5} = 31.6$$

(iii) Alkaline KMnO<sub>4</sub>:

$$MnO_4 + e \longrightarrow MnO_4^{2-}$$

Eq. mass = Mol. mass = 158.0

(iv) Neutral KMnO<sub>4</sub>:

$$MnO_4^- + 2H_2O + 3e \longrightarrow MnO_2 + 4OH^-$$

Eq. mass of KMnO<sub>4</sub> = 
$$\frac{\text{Mol. mass}}{3} = \frac{158}{3} = 52.67$$

(c) Oxidation number concept: According to this concept,

Equivalent mass =  $\frac{\text{Molecular mass}}{\text{Total change in oxidation number}}$ 

#### **Examples:**

(i) Acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is reduced to chromic sulphate in presence of dilute sulphuric acid.

Total change in O.N. = (12 - 6) = 6

Eq. mass of 
$$K_2Cr_2O_7 = \frac{Mol. \text{ mass}}{6} = \frac{294.2}{6} = 49.03$$

(ii) KMnO<sub>4</sub> (acidic medium), KMnO<sub>4</sub>  $\longrightarrow$  MnSO<sub>4</sub> Change in O.N. = (7 - 2) = 5Eq. mass =  $\frac{\text{Mol. mass}}{5} = \frac{158}{5} = 31.6$ 

(iii) KMnO<sub>4</sub> (alkaline medium), KMnO<sub>4</sub> 
$$\longrightarrow$$
 K<sub>2</sub>MnO<sub>4</sub> Change in O.N. =  $(7 - 6) = 1$  Eq. mass = Mol. mass = 158

- (iv) KMnO<sub>4</sub> (neutral medium), KMnO<sub>4</sub>  $\longrightarrow$   $\stackrel{+4}{\text{MnO}_2}$ Change in O.N. = (7 - 4) = 3Eq. mass =  $\frac{\text{Mol. mass}}{3} = \frac{158}{3} = 52.67$
- (v) Equivalent mass of a reducing agent:
- (a) Available oxygen method: The amount of reducing agent which combines with 8 g of oxygen is called its equivalent mass.

Examples: (i) Acidified ferrous ammonium sulphate:

$$\begin{array}{c} 2[FeSO_4\cdot(NH_4)_2SO_4\cdot 6H_2O] \ + \ H_2SO_4 \ + \ O \longrightarrow Fe_2(SO_4)_3 \\ 2 \ mol. \ mass \\ + \ 2(NH_4)_2SO_4 \ + \ 13H_2O \end{array}$$

Eq. mass of ferrous ammonium sulphate

$$= \frac{2 \text{ Mol. mass}}{16} \times 8$$

$$= \text{Mol. mass} = 392.0$$
(COOH

(ii) Oxalic acid:  $\begin{pmatrix} COOH \\ | & \cdot 2H_2O \\ COOH \end{pmatrix}$ COOH  $\begin{pmatrix} 2H_2O + O \longrightarrow 2CO_2 + 3H_2O \\ COOH & 16 g \end{pmatrix}$ mol. mass

Eq. mass of oxalic acid = 
$$\frac{\text{Mol. mass}}{16} \times 8 = \frac{126 \times 8}{16} = 63.0$$

(b) Electron concept: Equivalent mass of a reducing agent is equal to molecular mass divided by the number of electrons lost by one mole of the substance during its oxidation.

Examples: (i) Acidified ferrous ammonium sulphate:

$$Fe^{2+} \longrightarrow Fe^{3+} + e$$
  
Eq. mass = Mol. mass

(ii) Oxalic acid:

$$C_2O_4^2 \longrightarrow 2CO_2 + 2e$$
  
Eq. mass =  $\frac{\text{Mol. mass}}{2} = \frac{126}{2} = 63.0$ 

(c) Oxidation number concept: According to this concept,

Equivalent mass of reducing agent

Molecular mass

= Total change in O.N. of the oxidised element per molecule

Examples: (i) Ferrous 'ammonium sulphate:

$$\begin{array}{ccc}
+2 & & +3 \\
2\text{FeSO}_4 & \longrightarrow & \text{Fe}_2(\text{SO}_4)_3
\end{array}$$

Change in O.N. per Fe atom = (3 - 2) = 1

Eq. mass = Mol. mass

(ii) Oxalic acid:

H<sub>2</sub>C<sub>2</sub>O<sub>4</sub> 
$$\longrightarrow$$
 2CO<sub>2</sub>
O.N. per C atom; O.N. per C atom = +4

Total change in O.N. =  $(8-6) = 2$ 

Eq. mass =  $\frac{\text{Mol. mass}}{2} = \frac{126}{2} = 63.0$ 

# 17.5 CALCULATIONS OF VOLUMETRIC ANALYSIS

The following points should be kept in mind while making calculations of volumetric exercises.

(i) 1 g equivalent mass of a substance reacts completely with 1 g equivalent mass of any other substance. 1 g equivalent mass of a substance means equivalent mass of the substance in grams. For example,

1 g equivalent mass of NaOH = 40 g of NaOH 1 g equivalent mass of  $H_2SO_4 = 49$  g of  $H_2SO_4$ 1 g equivalent mass of KMnO<sub>4</sub> in acidic medium

= 31.6 g of  $KMnO_4$ 

1 g equivalent mass of hydrated oxalic acid

= 63 g of hydrated oxalic acid

Note: Equivalent mass is a variable quantity and depends on the reaction in which the substance takes part. The nature of the reaction should be known before writing the gram equivalent mass of the substance. For example, in the reactions:

$$2NaCl + 2H_2SO_4 \longrightarrow 2NaHSO_4 + 2HCl$$
 ...(i)

$$2\text{NaCl} + \text{H}_2\text{SO}_4 \longrightarrow \text{Na}_2\text{SO}_4 + 2\text{HCl}$$
 ...(ii)

The value of g equivalent mass of H<sub>2</sub>SO<sub>4</sub> in reaction (i) is 98 g and in reaction (ii) 49 g.

(ii) Number of g equivalents

 $= \frac{\text{Mass of the substance in gram}}{\text{Equivalent mass of the substance}}$ 

Number of g moles =  $\frac{\text{Mass of the substance in gram}}{\text{Molecular mass of the substance}}$ 

=  $\frac{\text{Volume in litres of the substance at N.T.P.}}{22.4}$ 

(only for gases)

Number of milli-equivalents =  $\frac{\text{Mass in gram} \times 1000}{\text{Equivalent mass}}$ 

Number of milli-moles =  $\frac{\text{Mass in gram} \times 1000}{\text{Molecular mass}}$ 

(iii) Molarity = 
$$\frac{\text{No. of moles of the solute}}{\text{No. of litres of the solution}} = \frac{w}{m \times V}$$

Molarity  $\times$  molecular mass = Strength of the solution (g/L)

No. of moles of the solute = Molarity  $\times$  No. of litres of solution

Mass of the solute in  $g(w) = Molarity \times No.$  of litres of solution  $\times Mol.$  mass of solute

Normality = 
$$\frac{\text{No. of g equivalents of the solute}}{\text{No. of litres of the solution}} = \frac{w}{E \times V}$$

Normality × Equivalent mass = Strength of the solution (g/L) No. of equivalents of the solute =

Normality  $\times$  No. of litres of solution Mass of the solute in g (w) = Normality  $\times$  No. of litres of solution  $\times$  Eq. mass of the solute

$$\frac{\text{Molecular mass}}{\text{Equivalent mass}} = n = \frac{\text{Normality}}{\text{Molarity}}$$

Normality =  $n \times Molarity$ 

(iv) Normality equation: When solutions A and B react completely.

$$N_A V_A = N_B V_B$$

Normality of  $A \times$  volume of A = Normality of  $B \times$  volume of B

or 
$$\frac{\text{Strength } A}{\text{Eq. mass } A} \times V_A = \frac{\text{Strength } B}{\text{Eq. mass } B} \times V_B$$

(v) When the solution is diluted, the following formulae can be applied:

or 
$$N_1V_1 = N_2V_2$$
  
or  $M_1V_1 = M_2V_2$   
or  $S_1V_1 = S_2V_2$ 

Before dilution = After dilution

(vi) If a number of acids are mixed, the combined normality of the mixture,  $N_x$  is given:

$$N_x V_x = N_1 V_1 + N_2 V_2 + N_3 V_3 + \dots$$

where  $V_x$  is the total volume of the mixture,  $N_1$  and  $V_1$  are the normality and volume respectively of one acid,  $N_2$  and  $V_2$  of the second acid, and so on.

#### SOME WORKED EXAMPLES

**Example 1.** What is the equivalent mass of:

- (a)  $H_3PO_4$  when neutralized to  $HPO_4^{2-}$
- (b) HClO<sub>4</sub>
- (c) NaIO<sub>3</sub> when reduced to  $I^-$
- (d) NaIO<sub>3</sub> when reduced to  $I_2$
- (e)  $Al(OH)_3$ .

#### Solution:

(a) Molecular mass of  $H_3PO_4 = (3 + 31 + 64) = 98$  g.  $H_3PO_4$  when neutralised to  $HPO_4^{2-}$ , two  $H^+$  ions have been replaced.

Thus, Eq. mass = 
$$\frac{\text{Mol. mass}}{\text{No. of replaceable hydrogen atoms}}$$
  
=  $\frac{98}{2}$  = 49.0 g

(b) HClO<sub>4</sub> molecule contains one replaceable hydrogen atom.

Thus, Eq. mass = 
$$\frac{\text{Mol. mass}}{1} = \frac{100.5}{1} = 100.5$$

(c) 
$$NaIO_3 \longrightarrow I^-$$
Oxidation no. +5 -1

Change in oxidation number = 6

Mol. mass of 
$$NaIO_3 = (23 + 127 + 48) = 198 g$$

Eq. mass of NaIO<sub>3</sub> = 
$$\frac{\text{Mol. mass}}{\text{Change in O.N.}} = \frac{198}{6} = 33.0$$

(d) 
$$NaIO_3 \longrightarrow I_2$$
Oxidation no. +5 0

Change in oxidation no. = 5

Eq. mass of NaIO<sub>3</sub> = 
$$\frac{198}{5}$$
 = 39.6

(e) The acidity of  $Al(OH)_3$  is 3.

Eq. mass of Al(OH)<sub>3</sub> = 
$$\frac{\text{Mol. mass}}{\text{Acidity}} = \frac{78}{3} = 26.0 \text{ g}$$

**Example 2.** Calculate the amount of  $KMnO_4$  present in 200 mL 0.1 N solution in acidic medium (Eq. mass  $KMnO_4 = 31.6$ ).

Solution: Strength of the given solution

= Normality 
$$\times$$
 Eq. mass  
=  $0.1 \times 31.6 = 3.16$  g/L

Amount of KMnO<sub>4</sub> in 200 mL =  $\frac{3.16}{1000}$  × 200 = 0.632 g

**Example 3.** 0.4 g of sodium hydroxide is present in 100 mL of the solution. What is its normality?

#### **Solution:**

Strength of the solution = 
$$\frac{0.4}{100} \times 1000$$
  
= 4.0 g/L  
We know that, Normality =  $\frac{\text{Strength}}{\text{Eq. mass}}$   
Eq. mass of NaOH = 40  
Normality =  $\frac{4}{40} = \frac{1}{10} = 0.1 \text{ N}$ 

Example 4. Determine the number of g equivalents of solute in (a) 100 mL of 5 N HCl (b) 250 mL of 0.1 N  $Na_2CO_3$ .

#### **Solution:**

We know that

Number of g equivalents = Normality  $\times$  Vol. of solution (litres)

- (a) Number of g equivalents of HCl =  $5 \times \frac{100}{1000} = 0.5$
- (b) Number of g equivalents of Na<sub>2</sub>CO<sub>3</sub>

$$=0.1 \times \frac{250}{1000} = 0.025$$

Example 5. Calculate the number of grams of solute in

- (a) 250 mL N/10 HCl
- (b) 500 mL N/20  $Na_2CO_3$  solution.

#### Solution:

(a) No. of g equivalents of HCl =  $\frac{1}{10} \times \frac{250}{1000} = \frac{1}{40}$ 

Mass of HCl = No. of g equivalents × Eq. mass =  $\frac{1}{40}$  × 36.5 = 0.9125 g

(b) No. of g equivalents of Na<sub>2</sub>CO<sub>3</sub> =  $\frac{1}{20} \times \frac{500}{1000} = \frac{1}{40}$ Mass of Na<sub>2</sub>CO<sub>3</sub> = No. of g equivalents × Eq. mass  $= \frac{1}{40} \times 53 = 1.33$  g **Example 6.** What volume of HCl of 2 N HCl be taken to form 500 mL N/10 solution of HCl?

#### **Solution:**

Let  $V_1$  volume of 2 N HCl be taken. Applying the formula,

$$N_1 \ V_1 = N_2 \ V_2$$
  
(Before dilution) (After dilution)  
 $N_1 = 2 \ N, \ V_1 = ?, \ N_2 = N/10$  and  $V_2 = 500 \ \text{mL}$   
So,  $2 \times V_1 = \frac{1}{10} \times 500$   
 $V_1 = \frac{500}{10 \times 2} = 25 \ \text{mL}$ 

i.e., 25 mL 2 N HCl is diluted by addition of 475 mL water to get 500 mL N/10 HCl solution.

**Example 7.** What volumes of 12 N HCl and 3 N HCl must be mixed to form one litre 6 N HCl?

#### Solution:

Let x mL of 12 N HCl and y mL of 3 N HCl be mixed to form one litre 6 N HCl.

So, 
$$x + y = 1000$$
 ...(i)  
Applying the formula  $N_1V_1 + N_2V_2 = N_3V_3$ ,  
 $N_1 = 12 \ N, \ V_1 = x, \ N_2 = 3 \ N, \ V_2 = y, \ N_3 = 6 \ N, \ V_3 = 1000$   
So,  $12x + 3y = 6 \times 1000$  ...(ii)

Putting the value of y = (1000 - x) from eq. (i) in eq. (ii), 12x + 3(1000 - x) = 6000

or 
$$12x - 3x + 3000 = 6000$$
  
or  $9x = 3000$ 

$$x = \frac{3000}{9} = 333.3 \text{ mL}$$

So, y = (1000 - x) = (1000 - 333.3) = 666.7 mLi.e., 333.3 mL 12 N HCl and 666.7 mL 3 N HCl are mixed.

**Example 8.** (a) What is the normality of a 96 per cent solution of  $H_2SO_4$  of specific gravity 1.84?

- (b) How many mL of 96 per cent sulphuric acid solution is necessary to prepare one litre  $0.1 N H_2SO_4$ ?
- (c) To what volume should 10 mL of 96 per cent  $H_2SO_4$  be diluted to prepare 2 N solution?

#### Solution:

Mass of 1 litre of 
$$H_2SO_4$$
 solution = Vol. × Density  
=  $1000 \times 1.84$   
=  $1840 \text{ g}$ 

Mass of H<sub>2</sub>SO<sub>4</sub> present in one litre 96% H<sub>2</sub>SO<sub>4</sub> solution

$$= \frac{96}{100} \times 1840$$
$$= 1766.4 \text{ g}$$

Strength of  $H_2SO_4$  solution = 1766.4 g/L

(a) Normality = 
$$\frac{\text{Strength}}{\text{Eq. mass}} = \frac{1766.4}{49}$$
  
= 36.05 N

(b) Let the volume taken be  $V_1$  mL.

Applying 
$$N_1V_1 = N_2V_2$$
  
 $N_1 = 36.05 \ N$ ,  $V_1 = ?$ ,  $N_2 = \frac{N}{10}$ ,  $V_2 = 1000 \ \text{mL}$   
 $36.05 \times V_1 = \frac{1}{10} \times 1000$   
So,  $V_1 = \frac{1000}{36.05 \times 10} = 2.77 \ \text{mL}$ 

i.e., 2.77 mL of H<sub>2</sub>SO<sub>4</sub> is diluted to one litre.

(c) 
$$N_B V_B = N_A V_A$$
Before dilution After dilution
$$10 \times 36.05 = V_A \times 2$$

$$V_A = 180.25 \text{ mL}$$

i.e., 10 mL of given H<sub>2</sub>SO<sub>4</sub> is diluted to 180.25 mL.

**Example 9.** What is the strength in g per litre of a solution of sulphuric acid-12 mL of which neutralise 15 mL of N/10 sodium hydroxide solution?

#### Solution:

Applying

ying 
$$N_1V_1 = N_2V_2$$
  
(NaOH)  $(H_2SO_4)$   
 $\frac{1}{10} \times 15 = N_2 \times 12$   
 $N_2 = \frac{15}{10 \times 12} = 0.125$   
Normality × Eq. mass = Strength (g/L)  
Strength =  $0.125 \times 49 = 6.125$  g/L

Example 10. 4.9 g of  $H_2SO_4$  is present in 100 mL of the solution. What is the molarity of the solution? Calculate its normality also.

#### Solution:

Solution:  
Strength (g/L) of 
$$H_2SO_4 = \frac{4.9}{100} \times 1000 = 49$$
  
Molarity =  $\frac{\text{Strength}}{\text{Mol. mass}} = \frac{49}{98} = 0.5 \text{ M}$   
Normality =  $n \times \text{Molarity}$   
 $n = \frac{\text{Mol. mass}}{\text{Eq. mass}} = \frac{98}{49} = 2$   
Normality =  $2 \times 0.5 = 1.0$ 

Hence, the  $H_2SO_4$  solution is 1 N.

**Example 11.** 25 mL of  $\frac{N}{10}$  caustic soda solution exactly neutralizes 20 mL of an acid solution containing 7.875 g of acid per litre. Calculate the equivalent mass of the acid.

#### Solution:

$$N_1V_1 = N_2V_2$$
(NaOH) (Acid)
$$\frac{1}{10} \times 25 = N_2 \times 20$$

$$N_2 = \frac{25}{10 \times 20} = 0.125$$

Strength = Normality  $\times$  Eq. mass

Eq. mass of the acid = 
$$\frac{7.875}{0.125}$$
  
= 63.00

Example 12. 150 mL of  $\frac{N}{10}$  HCl is required to react completely with 1.0 g of a sample of limestone. Calculate the percentage purity of calcium carbonate.

#### Solution:

150 mL 
$$\frac{N}{10}$$
 HCl = 150 mL  $\frac{N}{10}$  CaCO<sub>3</sub>  
CaCO<sub>3</sub> + 2HCl  $\longrightarrow$  CaCl<sub>2</sub> + H<sub>2</sub>O + CO<sub>2</sub>  
Mol. mass 2g Eq.

Eq. mass of 
$$CaCO_3 = \frac{40 + 12 + 48}{2} = \frac{100}{2} = 50$$

Mass of CaCO<sub>2</sub> present in 150 mL N/10 solution

$$= 50 \times \frac{1}{10} \times \frac{150}{1000} = 0.75 \text{ g} \left[ N \times E \times \frac{V}{1000} \right]$$
Purity =  $\frac{0.75}{1} \times 100 = 75\%$ 

Example 13. 0.63 g of dibasic acid was dissolved in water. The volume of the solution was made 100 mL, 20 mL of this acid solution required 10 mL  $\frac{N}{5}$  NaOH solution. What is the equivalent mass and molecular mass of the acid?

#### **Solution:**

$$N_1V_1 \equiv N_2V_2$$
(Acid) (NaOH)
$$N_1 \times 20 = \frac{1}{5} \times 10$$

$$N_1 = \frac{1}{5} \times \frac{10}{20} = \frac{1}{10}$$

Strength of the acid solution = Eq. mass of the acid × Normality

$$= E \times \frac{1}{10} = \frac{E}{10} \text{ g/L}$$

Mass of acid in 100 mL of the solution  $=\frac{E}{10} \times \frac{100}{1000} = \frac{E}{100}$ Mass of acid in 100 mL of the solution = 0.63 g (given)

So, 
$$\frac{E}{100} = 0.63$$
 or  $E = 60$   
Mol. mass = Basicity × Eq. mass  
 $= 2 \times 63 = 126$ 

Example 14. 10.875 g of a mixture of NaCl and Na<sub>2</sub>CO<sub>3</sub> was dissolved in water and the volume made upto 250 mL, 20 mL of this solution required 75.5 mL of  $\frac{N}{10}$  H<sub>2</sub>SO<sub>4</sub>. Find out the percentage composition of the mixture.

#### Solution:

Only Na<sub>2</sub>CO<sub>3</sub> will react with H<sub>2</sub>SO<sub>4</sub>.  
Applying 
$$N_1V_1 \equiv N_2V_2$$
  
(Na<sub>2</sub>CO<sub>3</sub>) (H<sub>2</sub>SO<sub>4</sub>)

$$N_1 \times 20 = 75.5 \times \frac{1}{10}$$

$$N_1 = \frac{75.5}{20 \times 10} = 0.3775$$

$$Na_2CO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O + CO_2$$
1 mol. mass 2 g eq.

Eq. mass of Na\_2CO\_3 =  $\frac{106}{2}$  = 53

Mass of Na<sub>2</sub>CO<sub>3</sub> present in 250 mL 0.3775 N solution
$$= \frac{N \times E \times V}{1000} = \frac{0.3775 \times 53 \times 250}{1000}$$

$$= 5.0018 \text{ g}$$
Mass of NaCl =  $(10.875 - 5.0018) = 5.8732 \text{ g}$ 

$$\text{Na2CO}_3 = \frac{5.0018}{10.875} \times 100 = 45.99\%$$

$$\text{NaCl} = \frac{5.8732}{10.875} \times 100 = 54.0\%$$

**Example 15.** A quantity of ammonium chloride was heated with 100 mL of 0.8 N NaOH solution till the reaction was complete. The excess of NaOH was neutralised with 12.5 mL of  $0.75\ NH_2SO_4$ . Calculate the quantity of ammonium chloride. **Solution :** 

12.5 mL of 0.75 N H<sub>2</sub>SO<sub>4</sub>  $\equiv$  12.5 mL of 0.75 N NaOH 12.5 mL of 0.75 N NaOH  $\equiv$  11.72 mL of 0.8 N NaOH

NaOH solution used by NH<sub>4</sub>Cl

= 
$$(100 - 11.72)$$
 mL of  $0.8 N$  NaOH  
=  $88.28$  mL of  $0.8 N$  NaOH  
=  $88.28$  mL of  $0.8 N$  NH<sub>4</sub>Cl

Mass of NH<sub>4</sub>Cl present in 88.28 mL of 0.8 N NH<sub>4</sub>Cl solution  $= \frac{N \times E \times V}{1000} = \frac{0.8 \times 53.5 \times 88.28}{1000}$  = 3.7783 g

[Eq. mass of 
$$NH_4Cl = 53.5$$
]

**Example 16.** A sample of  $Na_2CO_3 \cdot H_2O$  weighing 0.62 g is added to 100 mL of 0.1 N sulphuric acid. Will the resulting solution be acidic, basic or neutral? [At. mass H = 1, C = 12, O = 16, Na = 23, S = 32]

#### **Solution:**

Mass of  $Na_2CO_3 \cdot H_2O = 0.62$  g

No. of g equivalents = 
$$\frac{\text{Mass}}{\text{Eq. mass}} = \frac{0.62}{62} = 0.01$$

[Eq. mass of Na<sub>2</sub>CO<sub>3</sub>·H<sub>2</sub>O = 
$$\frac{124}{2}$$
 = 62]

No. of g equivalents of 
$$H_2SO_4$$
 in 100 mL =  $\frac{0.1}{1000} \times 100$   
=  $\frac{0.1}{10} = 0.01$ 

Both the substances are present in same equivalent; they will completely neutralise each other and, hence, the resulting solution will be neutral.

**Example 17.** 0.1435 g AgCl is obtained from 20 mL HCl. Determine the normality of the acid. [H = 1, Cl = 35.5, Ag = 108]

**Solution:** 

**Solution:** 

$$\begin{array}{ccc} \text{AgNO}_3 + \text{HCl} & \longrightarrow \text{AgCl} + \text{HNO}_3 \\ 170 & 36.5 & 143.5 \\ 1 \text{ g eq.} & 1 \text{ g eq.} & 1 \text{ g eq.} \end{array}$$

Mass of AgCl obtained = 0.1435 g

No. of g equivalents = 
$$\frac{0.1435}{1435}$$
 = 0.001

Thus, 20 mL of HCl will also contain 0.001 g equivalent of HCl.

Normality of HCl = 
$$\frac{0.001}{20} \times 1000$$
  
= 0.05 N

**Example 18.** 40 mL of HCl is exactly neutralised by 20 mL of NaOH solution. The resulting neutral solution is evaporated to dryness and the residue is found to have a mass of 0.117 g. Calculate the normality of the HCl and NaOH.

$$HCl + NaOH \longrightarrow NaCl + H_2O$$
  
36.5 40 58.5  
1 g eq. 1 g eq. 1 g eq.

Mass of NaCl obtained = 0.117 g

Eq. mass of 
$$NaCl = 58.5$$

No. of g equivalents of NaCl = 
$$\frac{0.117}{58.5}$$
 = 0.002

Thus,  $0.002~\rm g$  eq. of HCl will react with  $0.002~\rm g$  eq. of NaOH to form  $0.002~\rm g$  eq. NaCl.

Normality of HCl = 
$$\frac{0.002}{40} \times 1000 = 0.05 \ N$$
  
Normality of NaOH =  $\frac{0.002}{20} \times 1000 = 0.10 \ N$ 

**Example 19.** 1.03 g mixture of sodium carbonate and calcium carbonate require 20 mL N HCl for complete neutralisation. Calculate the percentage of sodium carbonate and calcium carbonate in the given mixture.

#### **Solution:**

$$\begin{array}{c} \text{Na}_2\text{CO}_3 + 2\text{HCl} \longrightarrow 2\text{NaCl} + \text{H}_2\text{O} + \text{CO}_2 \\ 106 & 2 \times 36.5 \\ \text{Eq. mass} & 53 & 36.5 \\ 1 \text{ g eq.} & 1 \text{ g eq.} \\ \text{CaCO}_3 + 2\text{HCl} \longrightarrow \text{CaCl}_2 + \text{H}_2\text{O} + \text{CO}_2 \\ 100 & 2 \times 36.5 \\ \text{Eq. mass} & 50 & 36.5 \\ 1 \text{ g eq.} & 1 \text{ g eq.} \end{array}$$

Let  $x \in CaCO_3$  be present in the mixture.

Mass of Na<sub>2</sub>CO<sub>3</sub> in the mixture = 
$$(1.03 - x)g$$

No. of g equivalents of 
$$CaCO_3 = \frac{x}{50}$$

No. of g equivalents of Na<sub>2</sub>CO<sub>3</sub> = 
$$\frac{(1.03 - x)}{53}$$

No. of g equivalents in 20 mL N HCl = 
$$\frac{\text{Normality} \times \text{Vol.}}{1000}$$
$$= \frac{1 \times 20}{1000} = \frac{1}{50}$$

At equivalence point,

No. of g equivalents of  $CaCO_3 + No.$  of g equivalents of  $Na_2CO_3 = No.$  of gram equivalents of HCl

$$\frac{x}{50} + \frac{1.03 - x}{53} = \frac{1}{50}$$
or
$$x = 0.50$$

$$CaCO_3 = 0.50 \text{ g}, \qquad \% \text{ CaCO}_3 = \frac{0.50}{1.03} \times 100 = 48.54$$

$$Na_2CO_3 = 0.53 \text{ g}, \qquad \% \text{ Na}_2CO_3 = \frac{0.53}{1.03} \times 100 = 51.46$$

**Example 20.** 1.325 g of anhydrous sodium carbonate are dissolved in water and the solution made upto 250 mL. On titration 25 mL of this solution neutralise 20 mL of a solution of sulphuric acid. How much water should be added to 450 mL of this acid solution to make it exactly N/12?

#### **Solution:**

Eq. mass of Na<sub>2</sub>CO<sub>3</sub> = 
$$\frac{\text{Mol.mass}}{2} = \frac{106}{2} = 53$$

250 mL of the sodium carbonate solution contains = 1.325 g 1000 mL of the sodium carbonate solution contains

Normality of Na<sub>2</sub>CO<sub>3</sub> solution = 
$$\frac{1.325 \text{ g}}{250} \times 1000 = 5.300 \text{ g}$$

Normality of Na<sub>2</sub>CO<sub>3</sub> solution =  $\frac{\text{Strength (g/L)}}{\text{Eq. mass}}$ 

$$= \frac{5.30}{53} = \frac{1}{10}N$$

Applying  $N_1V_1 = N_2V_2$ 

$$(Na_2CO_3) \quad (H_2SO_4)$$

$$\frac{1}{10} \times 25 = N_2 \times 20$$

$$N_2 = \frac{25}{10 \times 20} = \frac{1}{8}$$

Applying  $N_BV_B = N_AV_A$ 

$$(\text{Before dilution)} \quad (\text{After dilution})$$

$$\frac{1}{8} \times 450 = \frac{1}{12} \times V_A$$

$$V_A = \frac{450 \times 12}{8} = 675 \text{ mL}$$

Water to be added for dilution = (675 - 450) = 225 mL

**Example 21.** A sample of sodium carbonate contains sodium sulphate also. 1.5 g of the sample is dissolved in water and volume raised to 250 mL. 25 mL of this solution requires  $20 \text{ mL of } \frac{N}{10} H_2 SO_4$  solution for neutralisation. Calculate the percentage of sodium carbonate in the sample.

#### **Solution:**

Only Na<sub>2</sub>CO<sub>3</sub> will react with H<sub>2</sub>SO<sub>4</sub>.

Applying 
$$N_1V_1 = N_2V_2$$
 $(Na_2CO_3) = (H_2SO_4)$ 
 $N_1 \times 25 = 20 \times \frac{1}{10}$ 
 $N_1 = \frac{20}{25 \times 10} = 0.08$ 

Eq. mass of Na<sub>2</sub>CO<sub>3</sub> =  $\frac{\text{Mol. mass}}{2} = \frac{106}{2} = 53$ 

Mass of Na<sub>2</sub>CO<sub>3</sub> present in 250 mL 0.08 N solution

$$=\frac{N\times E\times V}{1000}=\frac{0.08\times 53\times 250}{1000}=1.06 \text{ g}$$

Percentage of Na<sub>2</sub>CO<sub>3</sub> in the mixture =  $\frac{1.06}{1.50} \times 100 = 70.67$ 

**Example 22.** A solution containing 4.2 g of KOH and  $Ca(OH)_2$  is neutralised by an acid. If it consumes 0.1 equivalent of the acid, calculate the composition of the sample.

#### Solution:

Let mass of KOH be present in mixture = a g and Mass of Ca(OH)<sub>2</sub> = (4.2 - a) g

Eq. mass of KOH = 56; Eq. mass of  $Ca(OH)_2 = \frac{74}{2} = 37$ No. of g equivalents of KOH + No. of g equivalents of  $Ca(OH)_2$ = No. of g equivalents of the acid

$$\frac{a}{56} + \frac{(4.2 - a)}{37} = 0.1$$
or
$$37a - 56a = 0.1 \times 56 \times 37 - 4.2 \times 56$$
or
$$19a = 28$$

$$a = \frac{28}{19} = 1.47$$

Mass of KOH in the sample = 1.47 g

Percentage of KOH = 35

and Percentage of  $Ca(OH)_2 = 100 - 35 = 65$ 

**Example 23.** 1.725 g of a metal carbonate is mixed with 300 mL of  $\frac{N}{10}$  HCl. 10 mL of  $\frac{N}{2}$  sodium hydroxide were required to neutralise excess of the acid. Calculate the equivalent mass of the metal carbonate.

#### Solution:

10 mL of 
$$\frac{N}{2}$$
 NaOH solution  
= 10 mL of  $\frac{N}{2}$  HCl solution  
= 50 mL of  $\frac{N}{10}$  HCl solution

Volume of  $\frac{N}{10}$  HCl used for neutralisation = 300 – 50 = 250 mL

250 mL of  $\frac{N}{10}$  HCl = 250 mL of  $\frac{N}{10}$  metal carbonate solution Let the equivalent mass of metal carbonate be E. Mass of metal carbonate present in solution

$$= \frac{N \times E \times V}{1000} = 1.725$$

$$= \frac{1 \times E \times 250}{10 \times 1000} = 1.725$$
$$= \frac{E}{40} = 1.725$$
$$E = 40 \times 1.725 = 69$$

Example 24. 1.575 g of oxalic acid  $(COOH)_2$ · $xH_2O$  are dissolved in water and the volume made upto 250 mL. On titration 16.68 mL of this solution requires 25 mL of  $\frac{N}{15}$  NaOH solution for complete neutralisation. Calculate x.

**Solution:** 

25 mL of 
$$\frac{N}{15}$$
 NaOH solution = 25 mL of  $\frac{N}{15}$  oxalic acid

Mass of oxalic acid present in 25 mL of  $\frac{N}{15}$  oxalic acid solution

$$= \frac{N \times E \times V}{1000} = \frac{1 \times (90 + 18x) \times 25}{15 \times 2 \times 1000}$$
$$= \frac{(90 + 18x)}{1200} g$$

Actually  $\frac{(90+18x)}{1200}$  g oxalic acid is present in 16.68 mL solution.

250 mL of the solution contains oxalic acid

$$= \frac{(90+18x)\times 250}{1200\times 16.68} = 1.575 \text{ (given)}$$
or
$$90+18x = \frac{1.575\times 1200\times 16.68}{250} = 126$$
or
$$18x = 126-90 = 36$$

$$x = 2$$

# 17.6 TO DETERMINE THE AMOUNT OF SODIUM HYDROXIDE AND SODIUM CARBONATE IN A GIVEN MIXTURE

The method involves the use of two indicators, phenolphthalein and methyl orange. When a mixture of sodium hydroxide and sodium carbonate is titrated with a standard solution of hydrochloric acid, using phenolphthalein as indicator, the strong base is neutralised first.

$$NaOH + HCl \longrightarrow NaCl + H_2O$$
 ...(i)

After the completion of above reaction, the carbonate is converted completely to bicarbonate.

$$Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$$
 ...(ii)

At this point, phenolphthalein changes from pink to colourless marking the first end point. Methyl orange is added now and orange-yellow colour is developed.

On adding acid, the bicarbonate is converted to carbonic acid and colour changes to red marking the second end point.

$$NaHCO_3 + HCl \longrightarrow NaCl + H_2CO_3$$
 ...(iii)

Let  $V_1$  mL of acid be required upto first end point and  $V_2$  mL of acid be required from first end point to second end point.

V <sub>1</sub> mL	NaOH	$(V_1 - V_2) \text{ mL}$ acid
1st end point	$\frac{1}{2}$ Na <sub>2</sub> CO <sub>3</sub>	ì
$V_2$ mL 2nd end point	$\frac{1}{2}$ Na <sub>2</sub> CO <sub>3</sub>	$2V_2 \text{ mL}$ Acid

Suppose, VmL of alkali solution is titrated with hydrochloric acid of normality N. From the above readings, it is possible to calculate the amounts of NaOH and Na<sub>2</sub>CO<sub>3</sub>.

Amount of NaOH in mixture = 
$$40 \times N \times \frac{(V_1 - V_2)}{V}$$
 g/L

Amount of Na<sub>2</sub>CO<sub>3</sub> in mixture = 
$$53 \times N \times \frac{2V_2}{V}$$
 g/L

#### 17.6.19 TO DETERMINE THE AMOUNT OF SODIUM CARBONATE AND BICARBONATE IN A MIXTURE

The method involves the successive use of two indicators, phenolphthalein and methyl orange. When a cold mixture of sodium carbonate and sodium bicarbonate is titrated against a standard solution of hydrochloric acid, using phenolphthalein as indicator, the sodium carbonate is converted into sodium bicarbonate first and colour changes from pink to colourless marking the first end point.

$$Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$$

If methyl orange is added at this stage, solution acquires orange yellow colour. On further addition of the acid, all the bicarbonate is neutralised and the colour changes to red. This is the second end point.

$$NaHCO_3 + HC1 \longrightarrow NaC1 + H_2CO_3$$

Suppose V mL of mixture is titrated with a standard hydrochloric acid of normality N. Let  $V_1$  mL of the acid be required upto first end point and  $V_2$  mL of the acid be required from first end point to second end point.

V <sub>1</sub> mL First end point	$\left\{ \frac{1}{2} \operatorname{Na_2CO_3} \right\}$	$2V_1$ mL
$V_2$ mL Second end point	$\left\{\begin{array}{c} \frac{1}{2} \text{Na}_2 \text{CO}_3 \\ \text{NaHCO}_3 \end{array}\right\}$	$(V_2 - V_1)$ mL

From these readings, it is possible to calculate the amounts of sodium carbonate and sodium bicarbonate.

Amount of Na<sub>2</sub>CO<sub>3</sub> = 
$$53 \times N \times \frac{2V_1}{V}$$
 g/L

Amount of NaHCO<sub>3</sub> = 84 × 
$$N \times \frac{(V_2 - V_1)}{V}$$
 g/L

**Example 25.** 25 mL of a mixture of NaOH and Na<sub>2</sub>CO<sub>3</sub> when titrated with N/10 HCl using phenolphthalein indicator required 25 mL HCl. The same volume of mixture when titrated with N/10 HCl using methyl orange indicator required 30 mL of HCl. Calculate the amount of Na<sub>2</sub>CO<sub>3</sub> and NaOH in one litre of this mixture.

#### **Solution:**

When phenolphthalein is the indicator, whole of NaOH has been neutralised and carbonate converted into bicarbonate, *i.e.*,

$$NaOH + HCl \longrightarrow NaCl + H_2O$$
  
 $Na_2CO_3 + HCl \longrightarrow NaHCO_3 + NaCl$ 

So, 25 mL  $\frac{N}{10}$  HCl = NaOH + 1/2 Na<sub>2</sub>CO<sub>3</sub> present in 25 mL of mixture

In another titration when methyl orange is the indicator, whole of NaOH has been neutralised and carbonate converted into carbonic acid, *i.e.*,

$$Na_2CO_3 + 2HCl \longrightarrow 2NaCl + H_2CO_3$$

30 mL  $\frac{N}{10}$  HCl = NaOH + Na<sub>2</sub>CO<sub>3</sub> present in 25 mL of mixture. Hence.

(30-25) mL  $\frac{N}{10}$  HCl  $\equiv \frac{1}{2}$  Na<sub>2</sub>CO<sub>3</sub> present in 25 mL of mixture. Hence,

10 mL 
$$\frac{N}{10}$$
 HCl  $\equiv$  Na<sub>2</sub>CO<sub>3</sub> present in 25 mL of mixture  
 $\equiv$  10 mL  $\frac{N}{10}$  Na<sub>2</sub>CO<sub>3</sub> solution

Amount of Na<sub>2</sub>CO<sub>3</sub> = 
$$\frac{53 \times 10}{10 \times 1000}$$
 = 0.053 g

This amount of Na<sub>2</sub>CO<sub>3</sub> is present in 25 mL of mixture. The amount present in one litre of mixture

$$= \frac{0.053}{25} \times 1000 = 2.12 \text{ g}$$

(30 – 10) mL  $\frac{N}{10}$  HCl ≡ NaOH present in 25 mL mixture ≡ 20 mL  $\frac{N}{10}$  NaOH

Amount of NaOH in 25 mL of mixture =  $\frac{40 \times 20}{10 \times 1000}$  = 0.08 g

The amount present in one litre of mixture =  $\frac{0.08}{25} \times 1000$ = 3.20 g

**Example 26.** 25 mL of a mixture of NaOH + Na<sub>2</sub>CO<sub>3</sub>, when titrated with N/10 HCl using phenolphthalein indicator required 25 mL HCl to decolourise phenolphthalein. At this stage methyl orange was added and addition of acid was continued. The second end point was reached after further addition of 5 mL of the acid. Calculate the amount of Na<sub>2</sub>CO<sub>3</sub> and NaOH in one litre of the solution.

#### **Solution:**

Between first and second end points,

5 mL  $\frac{N}{10}$  HCl =  $\frac{1}{2}$  Na<sub>2</sub>CO<sub>3</sub> present in 25 mL of a mixture

or 10 mL 
$$\frac{N}{10}$$
 HC1 = Na<sub>2</sub>CO<sub>3</sub> present in 25 mL of a mixture  
= 10 mL  $\frac{N}{10}$  Na<sub>2</sub>CO<sub>3</sub> = 0.053 g Na<sub>2</sub>CO<sub>3</sub>

Amount of Na<sub>2</sub>CO<sub>3</sub> in one litre of mixture = 
$$\frac{0.053}{25} \times 1000$$

$$= 2.12 \text{ g}$$

$$(25 - 5) \text{ mL } N/10 \text{ HCl} = \text{NaOH present in } 25 \text{ mL of mixture}$$

$$= 25 \text{ mL } \frac{N}{10} \text{ NaOH} = 0.08 \text{ g NaOH}$$

Amount of NaOH in one litre of mixture = 
$$\frac{0.08}{25} \times 1000$$
  
= 3.2 g

**Example 27.** A solution contains Na<sub>2</sub>CO<sub>3</sub> and NaHCO<sub>3</sub>. 10 mL of the solution required 2.5 mL of 0.1 M H<sub>2</sub>SO<sub>4</sub> for neutralisation using phenolphthalein as indicator. Methylorange is then added when a further 2.5 mL of 0.2 M H<sub>2</sub>SO<sub>4</sub> was required. Calculate the amount of Na<sub>2</sub>CO<sub>3</sub> and NaHCO<sub>3</sub> in one litre of the solution.

#### **Solution:**

2.5 mL of 0.1 
$$M$$
 H<sub>2</sub>SO<sub>4</sub> = 2.5 mL of 0.2  $N$  H<sub>2</sub>SO<sub>4</sub> =  $\frac{1}{2}$  Na<sub>2</sub>CO<sub>3</sub> present in 10 mL of mixture

So,

5 mL of 0.2 N H<sub>2</sub>SO<sub>4</sub> = Na<sub>2</sub>CO<sub>3</sub> present in 10 mL of mixture  

$$\equiv 5 \text{ mL of } 0.2 \text{ N Na2CO3}$$

$$\equiv \frac{0.2 \times 53}{1000} \times 5 = 0.053 \text{ g}$$

Amount of Na<sub>2</sub>CO<sub>3</sub> = 
$$\frac{0.053}{10} \times 1000 = 5.3$$
 g/L of mixture.

Between first and second end points,

= 2.5 mL of 0.2 
$$M$$
 H<sub>2</sub>SO<sub>4</sub> used  
= 2.5 mL of 0.4  $N$  H<sub>2</sub>SO<sub>4</sub> used

= 5 mL of 
$$0.2 N H_2 SO_4$$
 used

$$\equiv \frac{1}{2} \text{ Na}_2\text{CO}_3 + \text{Na}\text{HCO}_3 \text{ present in 10 mL of mixture}$$

$$(5 - 2.5) \text{ mL } 0.2 \text{ N H}_2\text{SO}_4$$

$$\equiv$$
 NaHCO<sub>3</sub> present in 10 mL of mixture  
 $\equiv$  2.5 mL 0.2 N NaHCO<sub>3</sub>  
 $\equiv \frac{0.2 \times 84}{1000} \times 2.5 = 0.042$  g

Amount of NaHCO<sub>3</sub> = 
$$\frac{0.042}{10}$$
 × 1000 = 4.20 g/L of mixture.

#### 17.7 KJELDAHL'S PROCESS

This method is used for the estimation of nitrogen in organic substances. This method is based on the fact that when an organic compound containing nitrogen is heated with concentrated sulphuric acid, the nitrogen in it is converted quantitatively into ammonium sulphate. The resultant liquid is then treated with excess of sodium hydroxide and the liberated ammonia gas is absorbed in excess of standard acid solution. The unreacted acid is estimated by titration with standard alkali. The difference of the two gives the volume of standard acid that actually combined with the evolved ammonia. From this, the percentage of nitrogen in the organic compound can be calculated.

Let the mass of organic substance be w g and V mL of N HCl is required for complete neutralisation of evolved ammonia; then,

$$V \text{ mL } N \text{ HCl} \equiv V \text{ mL } N \text{ NH}_3$$

$$17 \text{ g NH}_3 \equiv 14 \text{ g nitrogen}$$
Amount of nitrogen in  $V \text{ mL } N \text{ NH}_3 = \frac{14 \times N \times V}{1000}$ 

$$\% \text{ of nitrogen} = \frac{14 \times N \times V}{w \times 1000} \times 100$$

$$= \frac{1.4 \times N \times V}{w}$$

where N stands for normality of acid used
V stands for volume of acid used
and w stands for mass of organic substance.

**Example 28.** 1.0 g of an organic compound was analysed by Kjeldahl's process. The ammonia produced was absorbed in 80 mL of  $\frac{N}{5}$  H<sub>2</sub>SO<sub>4</sub>. The excess acid required 34 mL of  $\frac{N}{10}$  NaOH for neutralisation. Calculate the percentage of nitrogen in the compound.

#### **Solution:**

$$34 \text{ mL } \frac{N}{10} \text{ NaOH} \equiv 34 \text{ mL } \frac{N}{10} \text{ H}_2 \text{SO}_4$$
$$\equiv 17 \text{ mL } \frac{N}{5} \text{ H}_2 \text{SO}_4$$

Thus, acid used for neutralisation of  $NH_3 = (80 - 17)$ = 63 mL

So, 63 mL 
$$\frac{N}{5}$$
 H<sub>2</sub>SO<sub>4</sub> = 63 mL  $\frac{N}{5}$  NH<sub>3</sub>

Amount of nitrogen in the given sample =  $\frac{14}{5} \times \frac{63}{1000}$  g

% of nitrogen =  $\frac{14}{5} \times \frac{63}{1000} \times \frac{100}{1}$ 
=  $\frac{1.4 \times 63}{5}$ 

= 17.64

# SOME WORKED EXAMPLES ON OXIDATION-REDUCTION TITRATIONS

**Example 29.** 0.5 g of an oxalate was dissolved in water and the solution made to 100 mL. On titration 10 mL of this solution required 15 mL of  $N/20 \text{ KMnO}_4$ . Calculate, the percentage of oxalate in the sample.

#### **Solution:**

15 mL  $\frac{N}{20}$  KMnO<sub>4</sub> = 10 × Normality of oxalate solution

Normality of oxalate solution =  $\frac{15}{10} \times \frac{1}{20} = \frac{3}{40}$ 

Strength of oxalate solution = Normality  $\times$  Eq. mass of oxalate

= 
$$\frac{3}{40} \times 44 = 3.3$$
 g/L [Eq. mass  $C_2O_4^{2-} = \frac{88}{2} = 44$ ]

Amount of oxalate in 100 mL solution =  $\frac{3.3}{1000} \times 100 = 0.33$  g % of oxalate =  $\frac{0.33}{0.5} \times 100 = 66.0$ 

**Example 30.** How many mL of a 0.05 M  $KMnO_4$  solution are required to oxidise 2.0 g of  $FeSO_4$  in a dilute solution (acidic).

#### **Solution:**

$$10\text{FeSO}_4 + 2\text{KMnO}_4 + 8\text{H}_2\text{SO}_4 \longrightarrow \text{K}_2\text{SO}_4 + 2\text{MnSO}_4$$

$$10 \times 151.8 \quad 2 \times 158 \quad + 5\text{Fe}_2(\text{SO}_4)_3 + 8\text{H}_2\text{O}_4$$

 $10 \times 151.8$  g of FeSO<sub>4</sub> require KMnO<sub>4</sub> =  $2 \times 158$  g

2 g of FeSO<sub>4</sub> will require KMnO<sub>4</sub> = 
$$\frac{2 \times 158 \times 2}{10 \times 1518}$$
g

Suppose V mL of KMnO<sub>4</sub> solution (0.05 M) is required.

Amount of KMnO<sub>4</sub> in this solution =  $\frac{158 \times 0.05}{1000} \times V$ 

Thus, 
$$\frac{158 \times 0.05 \times V}{1000} = \frac{2 \times 158 \times 2}{10 \times 151.8}$$
$$V = 52.7 \text{ mL}$$

**Example 31.** 5.5 g of a mixture of  $FeSO_4$ .7 $H_2O$  and  $Fe_2(SO_4)_3$ .9 $H_2O$  required 5.4 mL of 0.1 N KMn $O_4$  solution for complete oxidation. Calculate the gram mole of hydrated ferric sulphate in the mixture.

[At. mass 
$$H = 1$$
,  $O = 16$ ,  $S = 32$ ,  $Fe = 56$ ]

#### **Solution:**

Only FeSO<sub>4</sub>·7H<sub>2</sub>O will be oxidised by KMnO<sub>4</sub>.

Mol. mass of  $FeSO_4 \cdot 7H_2O = 278$ 

As the conversion involves one electron,

$$Fe^{2+} \longrightarrow Fe^{3+} + e$$
,

The Eq. mass of  $FeSO_4.7H_2O = \frac{278}{1} = 278$ 

5.4 mL of 0.1 N KMnO<sub>4</sub>

 $\equiv 5.4 \text{ mL of } 0.1 \text{ N FeSO}_4.7\text{H}_2\text{O} \text{ solution}$ 

Amount of FeSO<sub>4</sub>·7H<sub>2</sub>O = 
$$\frac{0.1 \times 278}{1000} \times 5.4 = 0.15 \text{ g}$$

Amount of  $Fe_2(SO_4)_3.9H_2O = (5.5 - 0.15) = 5.35 g$ Mol. mass of  $Fe_2(SO_4)_3.9H_2O = 562$ 

No. of g moles of 
$$Fe_2(SO_4)_3 \cdot 9H_2O = \frac{Mass}{Mol. mass}$$
  
=  $\frac{5.35}{562} = 0.00952$   
=  $9.52 \times 10^{-3}$ 

**Example 32.** 50 mL of an aqueous solution of  $H_2O_2$  was treated with an excess of KI solution and dilute  $H_2SO_4$ . The liberated iodine required 20 mL 0.1 N  $Na_2S_2O_3$  solution for complete interaction. Calculate the concentration of  $H_2O_2$  in g/L.

#### Solution:

$$\begin{array}{c} \text{H}_2\text{O}_2 + 2\text{KI} + \text{H}_2\text{SO}_4 \longrightarrow \text{K}_2\text{SO}_4 + 2\text{H}_2\text{O} + \text{I}_2 \\ & 2\text{Na}_2\text{S}_2\text{O}_3 + \text{I}_2 \longrightarrow \text{Na}_2\text{S}_4\text{O}_6 + 2\text{NaI} \end{array}$$

Eq. mass 
$$H_2O_2 = \frac{34}{2} = 17$$

20 mL 0.1 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 20 mL 0.1 N I<sub>2</sub> solution  $\equiv$  20 mL 0.1 N H<sub>2</sub>O<sub>2</sub> solution

Amount of H<sub>2</sub>O<sub>2</sub> in 50 mL aq. solution

$$= \frac{0.1 \times 17}{1000} \times 20 = 0.034 \text{ g}$$

Concentration in g/L = 
$$\frac{0.034}{50}$$
 × 1000 = 0.68

**Example 33.** 0.124 g of iron wire was dissolved in dilute  $H_2SO_4$  in oxygen free atmosphere and the resultant solution was titrated against 0.09672 N solution of KMnO<sub>4</sub>. The titre value was 22.90 mL. Calculate the percentage purity of iron wire.

#### **Solution:**

22.90 mL 0.09672 N KMnO<sub>4</sub>  $\equiv$  22.90 mL 0.09672 N FeSO<sub>4</sub> Amount of FeSO<sub>4</sub> in the solution =  $\frac{0.09672 \times 152 \times 22.90}{1000}$ = 0.3366 g

Amount of iron in 0.3366 g of FeSO<sub>4</sub> =  $\frac{56}{152}$  × 0.3366 = 0.124 g

Thus, percentage = 
$$\frac{0.124}{0.124} \times 100 = 100$$

The iron wire is 100% pure.

**Example 34.** A sample of hydrazine sulphate  $(N_2H_6SO_4)$  was dissolved in 100 mL of water. 10 mL of this solution was reacted with excess of FeCl<sub>3</sub> solution and warmed to complete the reaction. Ferrous ion formed was estimated and it required 20 mL of  $\frac{M}{50}$  KMnO<sub>4</sub>. Estimate the amount of hydrazine sulphate in one litre of solution.

Reactions: 
$$4 Fe^{3+} + N_2H_4 \longrightarrow N_2 + 4Fe^{2+} + 4H^+$$
  
 $MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$ 

#### **Solution:**

$$20 \text{ mL} \frac{M}{50} \text{ KMnO}_4 = 20 \text{ mL} \frac{N}{10} \text{ KMnO}_4$$

$$\left[ \text{Equivalent mass of KMnO}_4 = \frac{\text{Molecular mass}}{5} \right]$$

$$20 \text{ mL} \frac{N}{10} \text{ KMnO}_4 = 20 \text{ mL} \frac{N}{10} \text{ ferrous ion}$$

$$\equiv 20 \text{ mL} \frac{N}{10} \text{ FeCl}_3$$

$$\equiv 20 \text{ mL} \frac{N}{10} \text{ N}_2 \text{H}_6 \text{SO}_4$$

$$\text{Eq. mass N}_2 \text{H}_6 \text{SO}_4 = \frac{\text{Mol.mass}}{4} = \frac{130}{4} = 32.5$$

[Since change in O.N.  $(N_2H_4 \rightarrow N_2)$  per molecule = 4] Amount of hydrazine sulphate in 10 mL of solution

$$= \frac{1}{10} \times \frac{32.5}{1000} \times 20 = 0.065 \text{ g}$$

Amount of hydrazine sulphate in one litre of solution

$$= \frac{0.065}{10} \times 1000 = 6.50 \text{ g}$$

**Example 35.** 0.1 M KMnO<sub>4</sub> is used for the following titration. What volume of the solution in mL will be required to react with 0.158 g of  $Na_2S_2O_3$ ?

$$S_2O_3^{2-} + MnO_4^- + H_2O \longrightarrow MnO_2(s) + SO_4^{2-} + OH^-$$
  
(not balanced) [M.L.N.R. 1992]

#### Solution:

$$S_2O_3^{2-} \longrightarrow 2SO_4^{2-}$$

Change in oxidation number of sulphur per molecule of  $S_2O_3^{2-} = 2 \times (6-2) = 8$ 

Change in oxidation number of Mn per molecule of  $MnO_4^- = 7 - 4 = 3$ 

No. of moles in 0.158 g of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 
$$\frac{0.158}{158}$$
 = 1 × 10<sup>-3</sup>  
No. of equivalents = 8 × 10<sup>-3</sup>

Normality of 0.1 M KMnO<sub>4</sub> solution = 0.1  $\times$  3 = 0.3 Let V mL of volume of KMnO<sub>4</sub> be required; then

$$\frac{V}{1000} \times 0.3 = 8 \times 10^{-3}$$

$$V = \frac{8}{0.3} \times 10^{-3} \times 10^{3}$$

$$= 26.7 \text{ mJ}$$

**Example 36.** 25 mL of  $H_2O_2$  solution were added to excess of acidified solution of KI. The iodine so liberated required 20 mL of 0.1 N  $Na_2S_2O_3$  for titration. Calculate the strength of  $H_2O_2$  in terms of normality, percentage and volume.

[M.L.N.R. 1996]

#### **Solution:**

or

20 mL of 0.1 N 
$$Na_2S_2O_3$$

= 20 mL of 0.1  $N I_2$  solution = 20 mL of 0.1  $N H_2O_2$  solution = 25 mL of 0.08  $N H_2O_2$  solution

Mass of H<sub>2</sub>O<sub>2</sub> in 100 mL solution = 
$$\frac{0.08\times17\times100}{1000} = 0.136 \text{ g}$$
 
$$\% = 0.136$$

68 g  $H_2O_2$  evolve oxygen at N.T.P. = 22400 mL 0.00136 g H<sub>2</sub>O<sub>2</sub> evolve oxygen at N.T.P.

$$= \frac{22400}{68} \times 0.00136 = 0.448$$
 The solution is of 0.448 volume.

**Example 37.** 0.5 g mixture of  $K_2Cr_2O_7$  and  $KMnO_4$  was treated with excess of KI in acidic medium. Iodine liberated required 100 cm<sup>3</sup> of 0.15 N sodium thiosulphate solution for titration. Find the per cent amount of each in the mixture.

[Roorkee 1995]

#### **Solution:**

Let 'a' g of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> be present in the mixture.

Mass of KMnO<sub>4</sub> = 
$$(0.5 - a)$$
 g

Eq. mass of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> =  $\frac{\text{Mol. mass}}{6} = \frac{294}{6} = 49.0$ 

Eq. mass of KMnO<sub>4</sub> =  $\frac{\text{Mol. mass}}{5} = \frac{158}{5} = 31.6$ 

No. of equivalents of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> =  $\frac{a}{49.0}$ 

No. of equivalents of KMnO<sub>4</sub> =  $\frac{(0.5 - a)}{31.6}$ 

No. of equivalents of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> in 100 cm<sup>3</sup> of 0.15 N solution

 $= \frac{100 \times 0.15}{1000} = 0.015$ Equivalents of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> + Equivalents of KMnO<sub>4</sub>

≡ Equivalents of iodine  $\equiv$  Equivalents of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>  $\frac{a}{49.0} + \frac{(0.5 - a)}{31.6} = 0.015$ 17.4a = 1.274a = 0.0732

% of 
$$K_2Cr_2O_7 = \frac{0.0732 \times 100}{0.5} = 14.64$$
  
% of  $KMnO_4 = 85.36$ 

### Some Miscellaneous Worked Problems

**Example 38.** Calculate the normality of a solution obtained by mixing 100 mL  $\frac{N}{10}$  H<sub>2</sub>SO<sub>4</sub>, 50 mL  $\frac{N}{2}$  HNO<sub>3</sub> and 25  $mL\frac{N}{5}HCl$  solutions.

#### Solution:

Let the final normality be N.

Total volume = 
$$(100 + 50 + 25) = 175$$
 mL  
So,  $175 \times N = N_1V_1 + N_2V_2 + N_3V_3$   
 $(H_2SO_4)$  (HNO<sub>3</sub>) (HCl)

$$= \left(100 \times \frac{1}{10}\right) + \left(50 \times \frac{1}{2}\right) + \left(25 \times \frac{1}{5}\right)$$

$$= (10 + 25 + 5) = 40$$

$$N = \frac{40}{175} = 0.2286$$

Hence, normality of solution = 0.2286 N

**Example 39.** 0.5 g of fuming  $H_2SO_4$  (oleum) is diluted with water. This solution is completely neutralised by 26.7 mL of 0.4 N NaOH. Find the percentage of free SO<sub>2</sub> in the sample solution.

#### **Solution:**

or

Oleum consists of SO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub>.

Let the mass of  $SO_2$  in the given sample of oleum be = x g Mass of  $H_2SO_4$  in the given sample of oleum = (0.5 - x) g

Eq. mass of 
$$SO_3 = \frac{80}{2} = 40$$
;  
No. of g equivalents of  $SO_3 = \frac{x}{40}$   
 $[2NaOH + SO_3 \longrightarrow Na_2SO_4 + H_2O$   
 $2NaOH + H_2SO_4 \longrightarrow Na_2SO_4 + 2H_2O]$   
Eq. mass of  $H_2SO_4 = \frac{98}{2} = 49$   
No. of g equivalents of  $H_2SO_4 = \frac{(0.5 - x)}{49}$ 

Total no. of g equivalents = 
$$\frac{x}{40} + \frac{(0.5 - x)}{49}$$

26.7 mL of 0.4 N NaOH contain no. of equivalents of NaOH  $=\frac{0.4}{1000}\times26.7$ 

At equivalence point,

No. of g equivalents of NaOH = 
$$\frac{x}{40} + \frac{(0.5 - x)}{49}$$
  
So,  $\frac{0.4 \times 26.7}{1000} = \frac{49x + (40 \times 0.5 - 40x)}{40 \times 49}$   
 $x = \frac{0.9328}{9}$   
 $= 0.1036$   
Hence, % of free SO<sub>3</sub> =  $\frac{0.1036}{0.5} \times 100$   
 $= 20.72$ 

**Example 40.** 0.789 g of crystalline barium hydroxide is dissolved in water. For the neutralisation of this solution, 20 mL of  $\frac{N}{4}$  HNO<sub>3</sub> is required. How many molecules of water are present in one g mole of this base? [Ba = 137.4, O = 16.]N = 14, H = 11

#### Solution:

Let the molecular formula be  $Ba(OH)_2 \cdot xH_2O$ . Mol. mass of Ba(OH)<sub>2</sub>·xH<sub>2</sub>O = 137.4 + (2 × 16) + 2 × 1 + 18x= 171.4 + 18x

Eq. mass of Ba(OH)<sub>2</sub>·xH<sub>2</sub>O = 
$$\frac{171.4 + 18x}{2}$$
  
 $20 \text{ mL } \frac{N}{4} \text{ HNO}_3 = 20 \text{ mL } \frac{N}{4} \text{ Ba(OH)}_2 \cdot x\text{H}_2\text{O}$   
Amount of Ba(OH)<sub>2</sub>·xH<sub>2</sub>O =  $\frac{(171.4 + 18x)}{2 \times 4} \times \frac{20}{1000}$   
=  $\frac{171.4 + 18x}{400} \text{ g}$   
Amount of Ba(OH)<sub>2</sub>·xH<sub>2</sub>O = 0.789 g  
Hence,  $\frac{171.4 + 18x}{400} = 0.789$   
or  $171.4 + 18x = 0.789 \times 400$   
 $x = \frac{144.2}{18} = 8.01 \approx 8$ 

Thus, 8 water molecules are present in one g mole of the

Example 41. (i) What is the weight of sodium bromate and molarity of the solution necessary to prepare 85.4 mL of 0.672 N solution when the half reaction is

$$BrO_3^- + 6H^+ + 6e \longrightarrow Br^- + 3H_2O$$

(ii) What would be the weight as well as molarity if the half cell reaction is

$$2BrO_3^- + 12H^+ + 10e \longrightarrow Br_2 + 6H_2O$$

#### **Solution:**

(i) Molecular mass of NaBrO<sub>3</sub> = 
$$23 + 80 + (3 \times 16)$$
  
=  $151$ 

Each bromate ion takes up 6 electrons; therefore,

Eq. mass of NaBrO<sub>3</sub> = 
$$\frac{\text{Mol. mass}}{6} = \frac{151}{6}$$

Amount of NaBrO<sub>3</sub> in 85.5 mL 0.672 N solution

$$= \frac{0.672}{1000} \times \frac{151}{6} \times 85.5 = 1.446 \text{ g}$$

Molarity = 
$$\frac{\text{Normality}}{n} = \frac{0.672}{6} = 0.112 \text{ M}$$

(ii) Each bromate ion takes up 5 electrons; therefore,

Eq. mass of NaBrO<sub>3</sub> = 
$$\frac{\text{Mol. mass}}{5} = \frac{151}{5}$$

Amount of NaBrO<sub>3</sub> in 85.5 mL 0.672 N solution

$$= \frac{151}{5} \times \frac{0.672}{1000} \times 85.5$$

$$= 1.7352 \text{ g}$$
Molarity =  $\frac{\text{Normality}}{n} = \frac{0.672}{5} = 0.1344 \text{ M}$ 

Example 42. A piece of aluminium weighing 2.7 g is heated with 75 mL of  $H_2SO_4$  (sp. gr. 1.18, containing 24.7%  $H_2SO_4$  by mass). After the metal is carefully dissolved, the solution is diluted to 400 mL. Calculate the molarity of the free  $H_2SO_4$  in the resulting solution.

#### Solution:

Mass of 
$$H_2SO_4 = \frac{24.7}{100} \times 75 \times 1.18$$
  
= 21.8595 g

Reaction: 
$$2Al + 3H_2SO_4 \longrightarrow Al_2(SO_4)_3 + 3H_2$$
  
 $2 \times 27 \quad 3 \times 98$ 

H<sub>2</sub>SO<sub>4</sub> required for dissolving 2.7 g Al

$$=\frac{3\times98}{2\times27}\times2.7=14.7 \text{ g}$$

 $H_2SO_4$  left unreacted = (21.8595 - 14.7) = 7.1595 g 7.1595 g  $H_2SO_4$  is present in 400 mL.

Amount of H<sub>2</sub>SO<sub>4</sub> present in one litre = 
$$\frac{7.1595}{400} \times 1000$$
 g = 17.898 g  
No. of g moles of H<sub>2</sub>SO<sub>4</sub> =  $\frac{17.898}{98}$  = 0.1826  
Hence, molarity of H<sub>2</sub>SO<sub>4</sub> = 0.1826 *M*

Example 43. 0.261 g of a sample of pyrolusite was heated with excess of HCl and the chlorine evolved was passed in a

solution of KI. The liberated iodine required 90 mL  $\frac{N}{30}$  Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Calculate the percentage of MnO<sub>2</sub> in the sample.

#### Solution:

$$\begin{array}{c} \text{MnO}_2 + 4\text{HCI} \longrightarrow \text{MnCI}_2 + 2\text{H}_2\text{O} + \text{Cl}_2 \\ 2\text{KI} + \text{Cl}_2 \longrightarrow 2\text{KCI} + \text{I}_2 \\ 2\text{Na}_2\text{S}_2\text{O}_3 + \text{I}_2 \longrightarrow \text{Na}_2\text{S}_4\text{O}_6 + 2\text{NaI} \\ 90 \text{ mL} \frac{N}{30} \text{Na}_2\text{S}_2\text{O}_3 \equiv 90 \text{ mL} \frac{N}{30} \text{ I}_2 \\ \equiv 90 \text{ mL} \frac{N}{30} \text{ Cl}_2 \\ \equiv 90 \text{ mL} \frac{N}{30} \text{ MnO}_2 \\ \text{Eq. mass of MnO}_2 = \frac{\text{Mol. mass}}{2} = \frac{87}{2} \\ \text{[Since change in O.N. is from 4 to 2]} \\ \text{Amount of MnO}_2 = \frac{87}{2 \times 30} \times \frac{90}{1000} = 0.1305 \text{ g} \\ \% \text{ of MnO}_2 = \frac{0.1305}{0.261} \times 100 = 50 \\ \end{array}$$

**Example 44.** Calculate the percentage of available chlorine in a given sample of bleaching powder from the following data:

3.55 g of bleaching powder when treated with acetic acid and excess of KI liberated iodine which required 60 mL of 0.5 N sodium thiosulphate solution.

#### **Solution:**

60 mL 0.5 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 60 mL 0.5 N I<sub>2</sub>  
= 60 mL 0.5 N Cl<sub>2</sub>  
Amount of chlorine = 
$$\frac{35.5 \times 0.5}{1000} \times 60$$
  
= 1.065 g  
% available chlorine =  $\frac{1.065}{3.55} \times 100$   
= 30.0

Example 45. 0.50 g of a mixture of  $K_2CO_3$  and  $Li_2CO_3$  requires 30 mL of a 0.25 N HCl solution for neutralisation. What is the percentage composition of the mixture?

**Solution:** 

Let x g of  $K_2CO_3$  be present in the mixture.

Mass of 
$$Li_2CO_3 = (0.50 - x)$$

No. of g equivalents of 
$$K_2CO_3 = \frac{x}{69}$$

No. of g equivalents of 
$$\text{Li}_2\text{CO}_3 = \frac{(0.50 - x)}{37}$$

No. of g equivalents in 30 mL of 0.25 N HCl

$$=\frac{\text{Normality} \times \text{Volume}}{1000} = \frac{0.25 \times 30}{1000} = \frac{3}{400}$$

At equivalence point,

$$\frac{x}{69} + \frac{(0.50 - x)}{37} = \frac{3}{400}$$
So,  $x = 0.48$ 

$$K_2CO_3 = 0.48 \text{ g; or } 96\%$$

$$Li_2CO_3 = 0.02 \text{ g; or } 4\%$$

**Example 46.** 0.804 g sample of iron ore was dissolved in acid. Iron was reduced to +2 state and it required 47.2 mL of  $0.112 \, N \, KMnO_4$  solution for titration. Calculate the percentage of iron and  $Fe_3O_4$  in the ore.

#### **Solution:**

The titration involves the conversion of ferrous into ferric.

$$5\text{Fe}^{2+} + \text{MnO}_4^- + 8\text{H}^+ \longrightarrow 5\text{Fe}^{3+} + \text{Mn}^{2+} + 4\text{H}_2\text{O}$$
  
 $47.2 \text{ mL of } 0.112 \text{ N KMnO}_4 = 47.2 \text{ mL of } 0.112 \text{ N Fe}^{2+} \text{ ions}$   

$$= \frac{47.2 \times 0.112 \times 55.5}{1000} = 0.2934$$

Mass of iron = 0.2934 g

% of iron in the ore = 
$$\frac{0.2934}{0.804} \times 100 = 36.49$$

$$3Fe \longrightarrow Fe_3O_4$$

$$(3 \times 55.5) \qquad (3 \times 55.5 + 64)$$

166.5 g of iron form 230.5 g of Fe<sub>3</sub>O<sub>4</sub>.

0.2934 g of iron will form = 
$$\frac{230.5}{166.5} \times 0.2934 = 0.406$$
 g % of Fe<sub>3</sub>O<sub>4</sub> in the ore =  $\frac{0.406}{0.804} \times 100 = 50.5$ 

**Example 47.** An equal volume of a reducing agent is treated separately with  $1\,M\,KMnO_4$  in acid, neutral and alkaline media. The volume of  $KMnO_4$  required are 20 mL in acid, 33.4 mL in neutral and 100 mL in alkaline media. Find out the oxidation state of manganese in each reaction product. Give the balanced equations for all the three half reactions. Find out the volume of  $1\,M\,K_2Cr_2O_7$  consumed, if the same volume of the reducing agent is treated in acid medium.

#### **Solution:**

Let  $N_1$ ,  $N_2$  and  $N_3$  be the normalities of 1 M KMnO<sub>4</sub> solution in acid, neutral and alkaline mediums, respectively.

$$20 \text{ mL } N_1 \equiv 33.4 \text{ mL } N_2 \equiv 100 \text{ mL } N_3$$

In acidic medium, the half reaction is:

$$MnO_4^- + 8H^+ + 5e^- = Mn^{2+} + 4H_2O$$
  
1 M KMnO<sub>4</sub> = 5 N KMnO<sub>4</sub>

Thus, from above relation,

$$N_2 = \frac{20}{33.4} \times N_1 = \frac{20}{33.4} \times 5 \ N = 3 \ N$$

and

$$N_3 = \frac{20}{100} \times N_1 = \frac{20}{100} \times 5 \ N = 1 \ N$$

The equations in the three media are:

$$\begin{array}{ccc} MnO_{4}^{-} + 5e & \xrightarrow{Acid} & Mn^{2+} \\ \hline MnO_{4}^{-} + 3e & \xrightarrow{Neutral} & Mn^{4+} \\ \hline MnO_{4}^{-} + e & \xrightarrow{Alkaline} & Mn^{6+} \\ \end{array}$$

The balanced equations are:

$$MnO_4^- + 8H^+ + 5e \xrightarrow{Acid} Mn^{2+} + 4H_2O$$
 $MnO_4^- + 2H_2O + 3e \xrightarrow{Neutral} MnO_2 + 4OH^ MnO_4^- + e \xrightarrow{Alkaline} MnO_4^{2-}$ 

The balanced equation in the case of acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution can be written as:

$$Cr_2O_7^{2-} + 14H^+ + 6e \longrightarrow 3Cr^{3+} + 7H_2O$$
  
1  $M K_2Cr_2O_7 = 6 N K_2Cr_2O_7$ 

The volume required for the titration of the same volume of reducing agent with acidified  $K_2Cr_2O_7$  solution as follows:

20 mL 5 N KMnO<sub>4</sub> = V 6 N K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>  

$$V = \frac{20 \times 5}{6} = 16.67 \text{ mL}$$

Example 48. 5 mL of 8 N nitric acid, 4.8 mL of 5 N hydrochloric acid and a certain volume of 17 M sulphuric acid are mixed together and made upto 2 litres. 30 mL of this acid mixture exactly neutralise 42.9 mL of sodium carbonate solution containing one gram of Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O in 100 mL of water. Calculate the amount in grams of the sulphate ions in solution.

#### **Solution:**

Molecular mass of  $Na_2CO_3 \cdot 10H_2O = 286$ 

Equivalent mass of Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O = 
$$\frac{286}{2}$$
 = 143

100 mL solution of sodium carbonate contains = 1 g 1000 mL solution of sodium carbonate contains = 10 g

Normality of the solution = 
$$\frac{10}{143}$$

Applying the formula,

Normality of acid solution  $\times$  its volume

= Normality of sodium carbonate solution  $\times$  its volume

Normality of the acid solution = 
$$\frac{10 \times 42.9}{143 \times 30}$$
 = 0.1  
Let *V* mL be the volume of H<sub>2</sub>SO<sub>4</sub> taken.

$$8 \times 5 + 4.8 \times 5 + 34 \times V = 0.1 \times 2000$$

$$V = 4 \text{ mL}$$
Amount of  $SO_4^{2-} = \frac{\text{Normality} \times \text{eq. mass} \times \text{volume}}{1000}$ 

$$= \frac{34 \times 48 \times 4}{1000} = 6.528 \text{ g}$$

**Example 49.** 2.26 g of an ammonium salt were treated with 100 mL of normal NaOH solution and boiled till no more of ammonia gas was given off. The excess of NaOH solution left over required 60 mL normal sulphuric acid. Calculate the percentage of ammonia in the salt.

#### **Solution:**

60 mL normal  $H_2SO_4 \equiv 60$  mL normal NaOH Thus, (100-60) mL normal NaOH were consumed by ammonium salt.

So, 40 mL normal NaOH  $\equiv$  40 mL normal NH<sub>3</sub> Amount of NH<sub>3</sub> in 40 mL normal NH<sub>3</sub>

$$= \frac{\text{Eq. mass of NH}_3 \times 40}{1000} = \frac{17 \times 40}{1000} = 0.68$$

So, % of ammonia in the ammonium salt =  $\frac{0.68}{2.26} \times 100$ = 30.09

**Example 50.** In a sample of sodium carbonate, some sodium sulphate is also mixed. 1.25 g of this sample is dissolved and the volume made up to 250 mL. 25 mL of this solution neutralises  $20 \, \text{mL of} \, \frac{N}{10}$  sulphuric acid. Calculate the percentage of sodium carbonate in the sample.

#### **Solution:**

25 mL of sample solution neutralises = 20 mL  $\frac{N}{10}$  H<sub>2</sub>SO<sub>4</sub> 250 mL of sample solution will neutralise

$$= 200 \text{ mL } \frac{N}{10} \text{ H}_2\text{SO}_4$$

$$= 200 \text{ mL } \frac{N}{10} \text{ H}_2\text{SO}_4 = 200 \text{ mL } \frac{N}{10} \text{ Na}_2\text{CO}_3 \text{ solution}$$

$$= \frac{E \times N \times V}{1000}$$

$$= \frac{53 \times 200}{10 \times 1000} = 1.06$$
% of Na<sub>2</sub>CO<sub>3</sub> in the sample =  $\frac{1.06}{1.25} \times 100 = 84.9$ 

**Example 51.** 10 mL of a solution containing sulphuric acid and hydrochloric acid required 16 mL  $\frac{N}{8}$  caustic soda solution for neutralisation. On adding excess of barium chloride to 20 mL of the same solution of the mixture of the two acids, it gives 0.3501 g barium sulphate. What is the amount of hydrochloric acid per litre in the mixture of acids?

$$(Ba = 137.4, S = 32, O = 16, Cl = 35.5)$$

#### **Solution:**

Mol. mass of 
$$BaSO_4 = (137.4 + 32 + 64) = 233.4$$
  
 $H_2SO_4 + BaCl_2 = BaSO_4 + 2HCl$   
98 g 233.4 g

233.4 g of BaSO<sub>4</sub> is obtained from = 98 g of H<sub>2</sub>SO<sub>4</sub>  
0.3501 g of BaSO<sub>4</sub> is obtained from = 
$$\frac{98}{233.4} \times 0.3501$$
  
= 0.147 g of H<sub>2</sub>SO<sub>4</sub>

20 mL of acid mixture contains 0.147 g of  $H_2SO_4$  So,10 mL of acid mixture contains 0.0735 g of  $H_2SO_4$ 

Amount of NaOH in 16 mL  $\frac{N}{8}$  NaOH solution  $= \frac{E \times N \times V}{1000}$  $= \frac{40 \times 16}{8 \times 1000} = 0.08 \text{ g}$ 

$$H_2SO_4 + 2NaOH \longrightarrow Na_2SO_4 + 2H_2O$$
  
98 g 2 × 40 = 80 g

Thus, 98 g of H<sub>2</sub>SO<sub>4</sub> require = 80 g of NaOH

$$0.0735$$
 g of H<sub>2</sub>SO<sub>4</sub> will require =  $\frac{80}{98} \times 0.0735$  g of NaOH

$$= 0.06$$
 g of NaOH

Let the amount of HCl in 10 mL acid mixture be = x g HCl + NaOH  $\longrightarrow$  NaCl + H<sub>2</sub>O

$$HC1 + NaOH \longrightarrow NaC1 + H_2O$$
  
36.5 g 40 g  
36.5 g HCl require = 40 g of NaOH

x g HCl will require =  $\frac{40}{36.5}$  x g of NaOH = 1.0958 x g of NaOH 1.0958x + 0.06 = 0.08

$$x = \frac{(0.08 - 0.06)}{1.0958} = 0.01825 \text{ g}$$

Amount of HCl present in one litre of the acid, solution

$$= \frac{0.01825 \times 1000}{10} = 1.825$$

**Example 52.** 1.6 g of pyrolusite ore was treated with 50 cm<sup>3</sup> of 1.0 N oxalic acid and some sulphuric acid. The oxalic acid left undecomposed was raised to 250 cm<sup>3</sup> in a flask. 25 cm<sup>3</sup> of this solution when titrated with 0.1 N KMnO<sub>4</sub> required 32 cm<sup>3</sup> of the solution. Find the percentage of pure  $MnO_2$  in the sample and also the percentage of available oxygen. [Roorkee 1996]

#### **Solution:**

25 cm<sup>3</sup> of undecomposed oxalic acid required =  $32 \text{ cm}^3 0.1 \text{ N KMnO}_4 \text{ solution}$ 

Thus,  $250~{\rm cm}^3$  of undecomposed oxalic acid required

=  $320 \text{ cm}^3 0.1 \text{ N KMnO}_4 \text{ solution}$ 

 $= 32 \text{ cm}^3 \text{ 1 } N \text{ KMnO}_4 \text{ solution}$ 

 $= 32 \text{ cm}^3 1 N \text{ oxalic acid solution}$ 

Oxalic acid used by pyrolusite

= 
$$(50 - 32)$$
 cm<sup>3</sup> 1 N solution  
=  $18$  cm<sup>3</sup> 1 N solution  
=  $18$  cm<sup>3</sup> 1 N MnO<sub>2</sub> solution

Mass of MnO<sub>2</sub> = 
$$\frac{N \times E \times V}{1000} = \frac{1 \times 18 \times 87}{1000 \times 2} = 0.783$$
 g  
Percentage of MnO<sub>2</sub> =  $\frac{0.783}{1.6} \times 100 = 48.9$   
MnO<sub>2</sub>  $\longrightarrow$  MnO + O  
87 g 16 g  
Oxygen given by 0.783 g MnO<sub>2</sub> =  $\frac{16}{87} \times 0.783 = 0.144$  g  
% of available oxygen =  $\frac{0.144}{1.6} \times 100 = 9.0$ 

**Example 53.** A mixture of  $H_2C_2O_4$  and  $NaHC_2O_4$  weighing 2.02 g was dissolved in water and the solution made up to one litre. 10 mL of this solution required 3.0 mL of 0.1 N NaOH solution for complete neutralisation. In another experiment, 10 mL of same solution in hot dilute  $H_2SO_4$  medium required 4 mL of 0.1 N KMnO<sub>4</sub> for complete neutralisation. Calculate the amount of  $H_2C_2O_4$  and  $NaHC_2O_4$  in the mixture.

[I.I.T. 1990]

#### **Solution:**

Let mass of  $H_2C_2O_4$  present in the mixture be = a g in 1 litre and mass of  $NaHC_2O_4$  present in the mixture be = b g in 1 litre For acid base reaction

$$\begin{aligned} &H_2C_2O_4 + 2NaOH \longrightarrow Na_2C_2O_4 + 2H_2O \\ &Eq. \text{ mass of } H_2C_2O_4 = \frac{Mol. \text{mass}}{2} = \frac{90}{2} = 45 \\ &NaHC_2O_4 + NaOH \longrightarrow Na_2C_2O_4 + H_2O \\ &Eq. \text{ mass of } NaHC_2O_4 = \frac{Mol. \text{mass}}{1} = 112 \end{aligned}$$

Now.

Equivalents of  $H_2C_2O_4$  + Equivalents of  $NaHC_2O_4 = \frac{3 \times 0.1}{1000}$  in 10 mL solution in 10 mL solution

$$\frac{a \times 10}{45 \times 1000} + \frac{b \times 10}{112 \times 1000} = \frac{3 \times 0.1}{1000}$$

or 
$$112a + 45b = \frac{3 \times 0.1 \times 45 \times 112}{10} = 151.2$$
 ...(i)

For redox reaction

Eq. mass of 
$$H_2C_2O_4 = \frac{90}{2} = 45$$
;

Eq. mass of NaHC<sub>2</sub>O<sub>4</sub> = 
$$\frac{112}{2}$$
 = 56

(Change in oxidation number of carbon per molecule = 2;  $C_2^{3+} \longrightarrow 2C^{4+}$ )

Now,

or

Equivalents of  $H_2C_2O_4$  + Equivalents of  $NaHC_2O_4 = \frac{4 \times 0.1}{1000}$  in 10 mL solution in 10 mL solution

$$\frac{a \times 10}{45 \times 1000} + \frac{b \times 10}{56 \times 1000} = \frac{4 \times 0.1}{1000}$$

56a + 45b = 100.8 ...(ii)

Solving equations (i) and (ii),

$$a = 0.9 \text{ g}$$
 and  $b = 1.12 \text{ g}$ 

**Example 54.** A 3.0 g sample containing  $Fe_3O_4$ ,  $Fe_2O_3$  and an inert impure substance is treated with excess of KI solution in presence of dilute  $H_2SO_4$ . The entire iron is converted to  $Fe^{2+}$  along with the liberation of iodine. The resulting solution is diluted to 100 mL. A 20 mL of the dilute solution requires 11.0 mL of 0.5 M  $Na_2S_2O_3$  solution to reduce the iodine present. A 50 mL of the diluted solution after complete extraction of iodine requires 12.8 mL of 0.25 M KMnO<sub>4</sub> solution in dilute  $H_2SO_4$  medium for oxidation of  $Fe^{2+}$ . Calculate the percentage of  $Fe_2O_3$  and  $Fe_3O_4$  in the original sample.

[LLT. 1996]

#### Solution:

Fe<sub>3</sub>O<sub>4</sub> is an equimolar mixture of Fe<sub>2</sub>O<sub>3</sub> and FeO. Thus, the sample contains Fe<sub>2</sub>O<sub>3</sub>, FeO and impurities. The amount of iodine liberated depends on the amount of Fe<sub>2</sub>O<sub>3</sub> and the entire iron is converted into Fe<sup>2+</sup>.

$$\begin{array}{c} -\mathrm{Fe_3O_4} + 2\mathrm{KI} + \mathrm{H_2SO_4} \longrightarrow 3\mathrm{FeO} + \mathrm{H_2O} + \mathrm{K_2SO_4} + \mathrm{I_2} \\ \mathrm{Fe_2O_3} + 2\mathrm{KI} + \mathrm{H_2SO_4} \longrightarrow 2\mathrm{FeO} + \mathrm{H_2O} + \mathrm{K_2SO_4} + \mathrm{I_2} \\ 5 \times 11.0 \ \mathrm{mL} \ \mathrm{of} \ 0.5 \ \mathit{M} \ \mathrm{Na_2S_2O_3} \equiv 55.0 \ \mathrm{mL} \ \mathrm{of} \\ 0.5 \ \mathit{N} \ \mathrm{Na_2S_2O_3} \ \mathrm{soln.} \\ \equiv 55.0 \ \mathrm{mL} \ \mathrm{of} \ 0.5 \ \mathit{N} \ \mathrm{Fe_2O_3} \ \mathrm{soln.} \\ \equiv 55.0 \ \mathrm{mL} \ \mathrm{of} \ 0.5 \ \mathit{N} \ \mathrm{Fe_2O_3} \ \mathrm{soln.} \\ = 27.5 \times 10^{-3} \ \mathrm{equivalent} \ \mathrm{Fe_2O_3} \ \mathrm{soln.} \\ = 13.75 \times 10^{-3} \ \mathrm{mole} \ \mathrm{Fe_2O_3} \\ 2 \times 12.8 \ \mathrm{mL} \ \mathrm{of} \ 0.25 \ \mathit{M} \ \mathrm{KMnO_4} \ \mathrm{soln.} \\ \equiv 25.6 \ \mathrm{mL} \ \mathrm{of} \ 1.25 \ \mathit{N} \ \mathrm{KMnO_4} \ \mathrm{soln.} \\ \equiv 25.6 \ \mathrm{mL} \ \mathrm{of} \ 1.25 \ \mathit{N} \ \mathrm{FeO} \ \mathrm{soln.} \\ \end{array}$$

= 25.6 mL of 1.25 N FeO soln.  
= 
$$32.0 \times 10^{-3}$$
 equivalent FeO  
=  $32.0 \times 10^{-3}$  mole FeO

Moles of FeO in 
$$Fe_3O_4 = 0.032 - 0.0275 = 0.0045$$
  
Mass of  $Fe_3O_4 = 0.0045 \times 232 = 1.044$  g

Moles of Fe<sub>2</sub>O<sub>3</sub> existing separately

$$= 0.01375 - 0.0045 = 0.00925$$
 Mass of Fe<sub>2</sub>O<sub>3</sub> = 0.00925 × 160 = 1.48 g  
% Fe<sub>3</sub>O<sub>4</sub> =  $\frac{1.044}{3}$  × 100 = 34.8  
% Fe<sub>2</sub>O<sub>3</sub> =  $\frac{1.48}{3}$  × 100 = 49.33

**Example 55.** Hydroxylamine reduces iron (III) according to the equation,

$$2NH_2OH + 4Fe^{3+} \longrightarrow N_2O(g) \uparrow + H_2O + 4Fe^{2+} + 4H^+$$

Iron (II) thus produced is estimated by titration with a standard permanganate solution. The reaction is:

$$MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$$

A 10 mL sample of hydroxylamine solution was diluted to one litre. 50 mL of this diluted solution was boiled with excess of iron (III) solution. The resulting solution required 12 mL of 0.02 M KMnO<sub>4</sub> solution for complete oxidation of iron (II).

Calculate the mass of hydroxylamine in one litre of the original solution.

#### **Solution:**

12 mL of 0.02 
$$M$$
 KMnO<sub>4</sub>  $\equiv$  12 mL of 0.1  $N$  KMnO<sub>4</sub>  $\equiv$  12 mL of 0.1  $N$  Fe<sup>2+</sup>  $\equiv$  12 mL of 0.1  $N$  NH<sub>2</sub>OH

Eq. mass of NH<sub>2</sub>OH = 
$$\frac{\text{Mol. mass}}{2} = \frac{33}{2} = 16.5$$

Mass of NH<sub>2</sub>OH in 12 mL of 0.1 N NH<sub>2</sub>OH soln.

$$= \frac{N \times E \times V}{1000} = \frac{0.1 \times 16.5 \times 12}{1000} = 0.0198 \text{ g}$$

50 mL of diluted solution contains  $NH_2OH = 0.0198$  g 1000 mL of diluted solution contains  $NH_2OH$ 

$$= \frac{0.0198}{50} \times 1000$$

10 mL of original solution contains  $NH_2OH = 0.396$  g 1000 mL of original solution contains  $NH_2OH$ 

$$= 100 \times 0.396 = 39.6 g$$

**Example 56.** A small amount of  $CaCO_3$  completely neutralises 525 mL of 0.1 N HCl and no acid is left in the end. After converting all calcium chloride to  $CaSO_4$ , how much plaster of Paris can be obtained? [Dhanbad 1991]

#### **Solution:**

525 mL of 0.1 N HCl = 525 mL of 0.1 N CaCl<sub>2</sub> = 525 mL of 0.1 N plaster of Paris

Molecular mass of plaster of Paris = 
$$CaSO_4 \cdot \frac{1}{2}H_2O$$
  
= 145

Equivalent mass of plaster of Paris =  $\frac{145}{2}$  = 72.5

Mass of plaster of Paris in 525 mL of 0.1 N solution

$$= \frac{N \times E \times V}{1000} = \frac{0.1 \times 72.5 \times 525}{1000}$$
$$= 3.806 \text{ g}$$

**Example 57.** 0.56 g of limestone was treated with oxalic acid to give  $CaC_2O_4$ . The precipitate decolourised 45 mL of 0.2 N KMnO<sub>4</sub> in acid solution. Calculate % of CaO in limestone.

#### **Solution:**

45 mL of 0.2 N KMnO<sub>4</sub> = 45 mL of 0.2 N CaC<sub>2</sub>O<sub>4</sub>  
= 45 mL of 0.2 N CaCO<sub>3</sub>  
= 45 mL of 0.2 N CaO  
Mass of CaO = 
$$\frac{N \times E \times V}{1000} = \frac{0.2 \times 28 \times 45}{1000}$$
  
= 0.252 g  
% of CaO in limestone =  $\frac{0.252}{0.56} \times 100$   
= 45

**Example 58.** A solution of 0.2 g of a compound containing  $Cu^{2+}$  and  $C_2O_4^{2-}$  ions on titration with 0.02 M KMnO<sub>4</sub> in presence of  $H_2SO_4$  consumes 22.6 mL oxidant. The resulting solution is neutralised by  $Na_2CO_3$ , acidified with dilute acetic acid and titrated with excess of KI. The liberated iodine required 11.3 mL of 0.05 M  $Na_2S_2O_3$  for complete reduction. Find out the mole ratio of  $Cu^{2+}$  and  $C_2O_4^{2-}$  in the compound.

[I.I.T. 1991]

**Solution:** 1st case: Only  $C_2O_4^{2-}$  ions are oxidised by  $KMnO_4$  solution.

Normality of KMnO<sub>4</sub> solution =  $0.02 \times 5 = 0.1 N$ 22.6 mL of 0.1 N KMnO<sub>4</sub> = 22.6 mL of 0.1 N C<sub>2</sub>O<sub>4</sub><sup>2-</sup> soln.

Mass of 
$$C_2O_4^{2-}$$
 ions =  $\frac{N \times E \times V}{1000} = \frac{N \times M \times V}{1000 \times 2}$  in the solution

No. of moles of 
$$C_2O_4^{2-}$$
 ions in the solution =  $\frac{N \times M \times V}{1000 \times 2 \times M}$   
=  $\frac{N \times V}{2000} = \frac{0.1 \times 22.6}{2000} = 11.3 \times 10^{-4}$ 

**2nd case :** Only  $Cu^{2+}$  ions are reduced by KI and iodine liberated is neutralised by  $Na_2S_2O_3$  solution.

Mass of Cu<sup>2+</sup> ions in the solution

$$= \frac{N \times E \times V}{1000} = \frac{N \times M \times V}{1000}$$

No. of moles of Cu<sup>2+</sup> ions in the solution

$$= \frac{N \times M \times V}{1000 \times M} = \frac{N \times V}{1000}$$
$$= \frac{0.05 \times 11.3}{1000} = 5.65 \times 10^{-4}$$

Molar ratio of 
$$\frac{Cu^{2+}}{C_2O_4^{2-}} = \frac{5.65 \times 10^{-4}}{11.3 \times 10^{-4}} = \frac{1}{2}$$

**Example 59.** 12 g of an impure sample of arsenious oxide was dissolved in water containing 7.5 g of sodium bicarbonate and the resulting solution was diluted to 250 mL. 25 mL of this solution was completely oxidised by 22.4 mL of a solution of iodine. 25 mL of this iodine solution reacted with same volume of a solution containing 24.8 g of sodium thiosulphate solution  $(Na_2S_2O_3\cdot5H_2O)$  in one litre. Calculate the percentage of arsenious oxide in the sample. (Atomic mass of As = 75)

[Roorkee 1999]

#### **Solution:**

:.

Normality of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> soln. = 
$$\frac{24.8}{248}$$
 = 0.1 *N*  
Applying  $N_1V_1 = N_2V_2$ 

Volume of As<sub>2</sub>O<sub>3</sub> soln. in NaHCO<sub>3</sub> × Normality of this soln. = Volume of iodine soln. × Normality of iodine soln.

$$25 \times N_1 = 22.4 \times 0.1$$
$$N_1 = \frac{22.4 \times 0.1}{25}$$

Amount of As<sub>2</sub>O<sub>3</sub> present in 250 mL of the solution

= 
$$N_1 \times \frac{\text{Equivalent mass of As}_2\text{O}_3}{1000} \times 250$$
  
=  $\frac{22.4 \times 0.1}{25} \times \frac{198}{4} \times \frac{250}{1000} = 1.1088 \text{ g}$ 

Percentage of 
$$As_2O_3 = \frac{1.1088}{12} \times 100 = 9.24$$

**Example 60.** Hydrogen peroxide solution (20 mL) reacts quantitatively with a solution of  $KMnO_4$  (20 mL) acidified with dilute  $H_2SO_4$ . The same volume of the  $KMnO_4$  solution is just decolourised by 10 mL of  $MnSO_4$  in neutral medium simultaneously forming a dark brown precipitate of hydrated  $MnO_2$ . The brown precipitate is dissolved in 10 mL of 0.2 M sodium oxalate under boiling condition in the presence of dilute  $H_2SO_4$ . Write the balanced equations involved in the reactions and calculate the molarity of  $H_2O_2$ . [LLT. 2001]

Solution

(i) 
$$MnO_2 + Na_2C_2O_4 + 2H_2SO_4 \longrightarrow MnSO_4 + Na_2SO_4$$
  
ppt. 1 mole  $+ 2CO_2 + 2H_2O_4$ 

$$mM \text{ of } MnO_2 = mM \text{ of } Na_2C_2O_4 = 10 \times 0.2 = 2$$

(ii) 
$$2KMnO_4 + 3MnSO_4 + 2H_2O \longrightarrow 5MnO_2 + K_2SO_4$$
  
 $2 \text{ mole}$  ppt.  $+ 2H_2O$ 

$$mM \text{ of } KMnO_4 = mM \text{ of } MnO_2 \times \frac{2}{5} = 2 \times \frac{2}{5} = \frac{4}{5}$$

(iii) 
$$2KMnO_4 + 3H_2SO_4 + 5H_2O_2 \longrightarrow K_2SO_4$$
  
2 mole 5 mole 5 mole 2 Mas  $O_4 + 2Mas O_4 + 8H_2O_4$ 

$$+ 2MnSO_4 + 8H_2O + 5O_2$$

:. 
$$mM ext{ of } H_2O_2 = mM ext{ of } KMnO_4 \times \frac{5}{2} = \frac{4}{5} \times \frac{5}{2} = 2$$

$$\therefore M \times 20 = 2$$

or 
$$M_{\rm H_2O_2} = \frac{2}{20} = 0.1 \ M$$

**Example 61.** The Mn<sub>3</sub>O<sub>4</sub> formed on strong heating of a sample of MnSO<sub>4</sub>·4H<sub>2</sub>O was dissolved in 100 cm<sup>3</sup> of 0.1 N

FeSO<sub>4</sub> containing dilute  $H_2SO_4$ . The resulting solution reacted completely with 50 cm<sup>3</sup> of KMnO<sub>4</sub> solution. 25 cm<sup>3</sup> of this KMnO<sub>4</sub> solution requires 30 cm<sup>3</sup> of 0.1 N FeSO<sub>4</sub> solution for complete reaction. Calculate the amount of MnSO<sub>4</sub>·4H<sub>2</sub>O in the sample. [Roorkee 2001]

#### Solution:

$$MnSO_4 \cdot 4H_2O \xrightarrow{Heat} Mn_3O_4$$

Mn<sub>3</sub>O<sub>4</sub> is dissolved in ferrous sulphate solution and is reduced from Mn<sup>(8/3)+</sup> to Mn<sup>2+</sup>. The excess of FeSO<sub>4</sub> is estimated by doing titration with KMnO<sub>4</sub> solution. The normality of KMnO<sub>4</sub> solution is determined by another ferrous sulphate solution.

For normality of KMnO<sub>4</sub> solution:

$$25 \times N = 30 \times 0.1$$
$$N = \frac{30 \times 0.1}{25} = \frac{3}{25}$$

Let the volume of unreacted FeSO<sub>4</sub> solution be V mL.

$$V \text{ mL of } 0.1 \text{ N FeSO}_4 = 50 \text{ mL of } \frac{3}{25} N \text{ KMnO}_4$$

or 
$$V = \frac{50 \times 3}{0.1 \times 25} = 60 \text{ mL}$$

$$\therefore$$
 Volume of FeSO<sub>4</sub> used for Mn<sub>3</sub>O<sub>4</sub> = (100 - 60) mL = 40 mL

40 mL of 0.1 N FeSO<sub>4</sub> 
$$\equiv$$
 40 mL of 0.1 N Mn<sub>3</sub>O<sub>4</sub>  
 $\equiv$  40 mL of 0.1 N MnSO<sub>4</sub>·4H<sub>2</sub>O

Mass of MnSO<sub>4</sub>·4H<sub>2</sub>O = 
$$\frac{E \times 0.1 \times 40}{1000} = \frac{E}{250}$$
 g

Equivalent mass of

MnSO<sub>4</sub>·4H<sub>2</sub>O = 
$$\frac{M}{\left(\frac{8}{3}-2\right)} = \frac{3M}{2} = \frac{3 \times 223}{2}$$

$$\therefore \text{ Mass of MnSO}_4 \cdot 4H_2O = \frac{3 \times 223}{2 \times 250}$$

$$= 1.338 g$$

- 9. 12 mL of 0.25 N sulphuric acid is neutralised with 15 mL of sodium hydroxide solution on titration. Calculate the normality of sodium hydroxide solution.
- **10.** What will be the volume of *N*/10 solution of oxalic acid obtained by dissolving 63 g of oxalic acid?

- 11. If 1.26 g of oxalic acid is dissolved in 250 mL of solution, find its normality. The equivalent mass of oxalic acid is 63.
- **12.** 50 mL of 0.2 N KMnO<sub>4</sub> is required for complete oxidation of 0.45 g of anhydrous oxalic acid. Calculate the normality of oxalic acid solution.
- 13. 30 mL of sodium carbonate solution is mixed with 20 mL of 0.8 N sulphuric acid. The resultant solution needed 20 mL of 0.7 N hydrochloric acid solution for complete neutralisation. Determine the strength of the sodium carbonate in grams per litre. (Take sodium carbonate to be anhydrous).
- 14. Find the equivalent mass of  $H_3PO_4$  in the reaction  $Ca(OH)_2 + H_3PO_4 \longrightarrow CaHPO_4 + 2H_2O$ (At. mass H = 1, O = 16, P = 31, Ca = 40)
- **15.** 316 g of sodium thiosulphate was dissolved in water and made up to 250 mL. What is the normality of the solution?
- **16.** Calculate the equivalent mass of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O and KBrO<sub>3</sub> with the help of the following equations:
  - (i)  $2S_2O_3^{2-} + I_2 \longrightarrow S_4O_6^{2-} + 2I^-$
  - (ii)  $BrO_3^- + 6H^+ + 6e \longrightarrow Br^- + 3H_2O$
- 17. 0.25 g of an oxalate salt was dissolved in 100 mL of water. 10 mL of this solution required 8 mL of N/20 KMnO<sub>4</sub> for its oxidation. Calculate the percentage of oxalate in the salt.
- 18. 1.13 g of an ammonium sulphate were treated with 50 mL of normal NaOH solution and boiled till no more ammonia was given off. The excess of the alkali solution left over was titrated with normal H<sub>2</sub>SO<sub>4</sub>. The volume required was 30 mL. Find out the percentage of NH<sub>3</sub> in the salt.
- 19. The normality of the mixture of HCl and H<sub>2</sub>SO<sub>4</sub> solution is N/5. 0.287 g of AgCl is obtained when 20 mL of this solution is treated with excess of AgNO<sub>3</sub>. Calculate the percentage of both the acids in the mixture.
- 20. 1.17 g of an impure sample of oxalic acid was dissolved and made up to 200 mL with water. 10 mL of this solution in acid medium required 8.5 mL of a solution of potassium permanganate containing 3.16 g per litre of oxidation. Calculate percentage purity of oxalic acid.
- 21. What amount of silver chloride will be obtained when 20 mL N/20 HCl is made to react with excess of AgNO<sub>3</sub>?
- 22. 1.0 g carbonate of a metal was dissolved in 50 mL N/2 HCl solution. The resulting liquid required 25 mL of N/5 NaOH solution to neutralise it completely. Calculate the equivalent mass of the metal carbonate.
- 23. 0.35 g of a metal was dissolved in 50 mL *N*-acid. The whole solution then required 20.85 mL of normal alkaline solution to neutralise the excess of the acid. Calculate the equivalent mass of the metal.
- 24. 2.650 g of anhydrous sodium carbonate are dissolved in water and the solution made up to 500 mL. On titration 50 mL of this solution neutralises 50 mL of a solution of sulphuric acid. How much water should be added to 450 mL of this acid as to make it exactly N/12?
- 25. Two acids A and B are titrated separately each time with 25 mL of N Na<sub>2</sub>CO<sub>3</sub> solution and require 10 mL and 40 mL respectively for complete neutralisation. What volume of A and B would you mix to produce one litre of normal acid solution?

- **26.** 1.64 g of a mixture of calcium carbonate and magnesium carbonate were dissolved in 50 mL of 0.8 N hydrochloric acid. The excess of the acid required 16 mL N/4 sodium hydroxide solution for neutralisation. Find out the percentage composition of the mixture of two carbonates.
- 27. What weight of zinc carbonate can just neutralise 300 mL N/10 sulphuric acid? (At. mass of Zn = 65.0)
- 28. 20 mL N/2 HCl, 60 mL N/10 H<sub>2</sub>SO<sub>4</sub> and 150 mL N/5 HNO<sub>3</sub> are mixed. Determine the normality of the mixture of the acids in solution.
- **29.** A sample of hydrochloric acid contains 20% of hydrochloride by mass. How many grams of this acid sample is necessary to completely interact with 50 g of calcium carbonate?
- **30.** 30 mL of *N*/10 HCl are required to neutralise 50 mL of a sodium carbonate solution. How many mL of water must be added to 30 mL of this solution so that the solution obtained may have a concentration equal to *N*/50?
- 31. 2.65 g of diacidic base was dissolved in water and made up to 500 mL. 20 mL of this solution completely neutralised 12 mL of N/6 HCl. Find out the equivalent mass and molecular mass of the base.
- 32. In a sample of sodium carbonate some sodium sulphate is mixed. 2.50 g of this sample is dissolved and the volume made up to 500 mL. 25 mL of this solution neutralises 20 mL of N/10 sulphuric acid. Calculate the percentage of sodium carbonate in the sample.
- 33. Some amount of NH<sub>4</sub>Cl was boiled with 50 mL of 0.75 N NaOH solution till the reaction was complete. After the completion of the reaction, 10 mL of 0.75 N H<sub>2</sub>SO<sub>4</sub> were required for the neutralisation of the remaining NaOH. Calculate the amount of NH<sub>4</sub>Cl taken.
- 34. 25 mL of a mixed solution of sodium carbonate and sodium bicarbonate required 10 mL of N/20 HCl when titrated in the presence of phenolphthalein but 25 mL of the same when titrated separately in presence of methyl orange required 25 mL of N/10 HCl. Calculate the amount of anhydrous sodium carbonate and bicarbonate in grams per litre of the solution.
- 35. 4 g of a mixture of NaCl and Na<sub>2</sub>CO<sub>3</sub> were dissolved in water and volume made up to 250 mL. 15 mL of this solution required 50 mL of N/10 HCl for complete neutralisation. Calculate the percentage composition of the original mixture.
- 36. 40 mL of a mixture of Na<sub>2</sub>CO<sub>3</sub> and NaOH when titrated against N/10 HCl, the end point with phenolphthalein was reached at 25 mL of HCl and at this stage methyl orange was added, the quantity of acid further required for second end point was 5 mL. Calculate the amount of Na<sub>2</sub>CO<sub>3</sub> and NaOH in g/L of the solution.
- 37. Find out the percentage of oxalate in a given sample of an oxalate salt of which when 0.3 g were dissolved in 100 mL of water required 90 mL of N/20 KMnO<sub>4</sub> solution for complete oxidation.
- **38.** A 1.0 g sample of H<sub>2</sub>O<sub>2</sub> solution containing 'x' per cent by weight requires x mL of a KMnO<sub>4</sub> solution for complete oxidation under acidic conditions. Calculate the normality of the KMnO<sub>4</sub> solution.

- 39. 25 g of a sample of ferrous sulphate was dissolved in water containing dilute H<sub>2</sub>SO<sub>4</sub> and the volume made up to one litre.
  25 mL of this solution required 20 mL of N/10 KMnO<sub>4</sub> solution for complete oxidation. Calculate the percentage of FeSO<sub>4</sub>·7H<sub>2</sub>O in the sample.
- **40.** (i) A sample of MnSO<sub>4</sub>:4H<sub>2</sub>O is strongly heated in air. The residue is Mn<sub>3</sub>O<sub>4</sub>.
  - (ii) The residue is dissolved in 100 mL of 0.1 N FeSO<sub>4</sub> containing dilute H<sub>2</sub>SO<sub>4</sub>.
  - (iii) The solution reacts completely with 50 mL of KMnO<sub>4</sub> solution.
  - (iv) 25 mL of KMnO<sub>4</sub> used in step (iii) required 30 mL of 0.1 N FeSO<sub>4</sub> solution for complete reaction.

Find the amount of  $MnSO_4$ · $4H_2O$  present in the sample. (At. mass of Mn = 55)

- 41. A sample of KCl is contaminated with NaCl. 4.176 g of the sample is dissolved in distilled water and the solution is made to 500 mL. 25 mL of the above solution required 27.50 mL of a solution of silver nitrate (normality factor 0.115) to react completely with it. Calculate the percentage contamination of the sample.
- **42.** Mercuric iodate  $[Hg_5(IO_6)_2]$  reacts with a mixture of KI and HCl according to the equation:

$$Hg_5(IO_6)_2 + 34KI + 24HC1 \longrightarrow 5K_2HgI_4 + 8I_2 + 24KC1 + 12H_2O$$

The liberated iodine is titrated with  $Na_2S_2O_3$  solution, 1.0 mL of which is equivalent to 0.0499 g of  $CuSO_4$ ·5H<sub>2</sub>O. What volume (in mL) of the  $Na_2S_2O_3$  solution will be required to react with iodine liberated from 0.7245 g of  $Hg_5(IO_6)_2$ ? [Hg = 200.5, Cu = 63.5, I = 127]

[Hint:  $1448.5 \text{ g Hg}_5(IO_6)_2 \equiv 8I_2 \equiv 16\text{CuSO}_4.5\text{H}_2\text{O}$ 

So, 0.7245 g 
$$Hg_5(IO_6)_2 \equiv \frac{16 \times 249.5 \times 0.7245}{1448.5}$$
 g  $CuSO_4 \cdot 5H_2O$  0.0499 g  $CuSO_4 \cdot 5H_2O \equiv 1$  mL of the given  $Na_2S_2O_3$ ]

- 43. 5.0 g of bleaching powder was suspended in water and volume made up to half a litre. 20 mL of this suspension when acidified with acetic acid and treated with excess of KI solution liberated iodine which required 20 mL of a decinormal hypo solution for titration. Calculate percentage of available chlorine in bleaching powder. [Roorkee 1990]
- **44.** To a solution of excess of KI in dilute H<sub>2</sub>SO<sub>4</sub>, 25 mL of an unknown solution of KMnO<sub>4</sub> were added. The liberated iodine was exactly reduced by 42.5 mL of *N*/10 Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> solution. Calculate the concentration of KMnO<sub>4</sub> solution.
- 45. In 20 mL of a solution of HCl, 3 g of CaCO<sub>3</sub> were dissolved, 0.5 g of CaCO<sub>3</sub> being left undissolved. Find out the strength of this solution in terms of (i) normality and (ii) g/L. Find the volume of this acid which would be required to make 1 litre of normal solution of this acid.
- **46.** 1.0 litre of a solution contains 5.3 g of Na<sub>2</sub>CO<sub>3</sub> and 8 g of NaOH. 20 mL of this solution are taken and titrated against *N*/10 HCl using separately (a) methyl orange as an indicator and (b) phenolphthalein as an indicator. What will be the titre values in these two cases?

- **47.** To 20 mL of a copper solution after necessary treatment were added excess of KI and the liberated iodine required 11.2 mL decinormal solution of hypo. Express the strength of the original solution in grams of copper per litre of the solution.
- **48.** 10 g of a commercial sample of copper sulphate were dissolved in water and the volume made up to 500 mL. 25 mL of this solution was treated with excess of KI and the liberated iodine required 30 mL of *N*/12 Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> solution. Calculate the percentage of copper in the sample.
- **49.** 0.28 g of a commercial sample of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> was dissolved in water. Excess of KI was added to it along with dilute H<sub>2</sub>SO<sub>4</sub>. Iodine liberated was then titrated against sodium thiosulphate solution containing 24.82 g of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O per litre. The thiosulphate solution required was 50 mL. Find the percentage purity of the sample of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>.
- **50.** A mixture containing KCl and NaCl was dissolved and total halide was determined by titration with silver nitrate. A sample weighing 0.3250 g required 51 mL of 0.1 N solution.

  Calculate the percentage of each salt in the sample.
- 51. 1.355 g of pyrolusite sample are added to 50 mL of 1 N oxalic acid solution containing sulphuric acid. After the reaction is completed, the contents are transferred to a measuring flask and the volume made up to 200 mL. 20 mL of this solution is titrated against KMnO<sub>4</sub> solution whose strength is 2 g/L and 31.6 mL of KMnO<sub>4</sub> solution are required. Calculate the percentage purity in the given sample of pyrolusite.
- 52. 0.5 g of bleaching powder was suspended in water an excess of KI added. On acidifying with dilute H<sub>2</sub>SO<sub>4</sub> iodine was liberated which required 50 mL of N/10 hyposolution. Calculate the percentage of available chlorine in bleaching powder.
- **53.** A compound contains C = 48% and H = 8%. On treating 0.48 g of the compound by Kjeldahl's method, the ammonia liberated required 19.2 mL of *N*/2 sulphuric acid for complete reaction. Determine the empirical formula of the compound.
- 54. 0.6 g of an organic compound was analysed. The ammonia thus produced was absorbed in 90 mL N/9 H<sub>2</sub>SO<sub>4</sub>. The remaining acid required 20 mL 0.1 N NaOH for neutralisation. Calculate the percentage of nitrogen in the compound.
- 55. 0.95 g of an organic compound after being digested with H<sub>2</sub>SO<sub>4</sub> was boiled with excess of NaOH. The liberated ammonia was absorbed in 100 mL N H<sub>2</sub>SO<sub>4</sub>. The acid left required 62.5 mL of N NaOH for neutralisation. Calculate the percentage of nitrogen in the compound.
- 56. Calculate the number of oxalic acid molecules in 100 mL of 0.02 N oxalic acid solution. [Roorkee 1991]

[**Hint**: Molarity = 
$$\frac{0.02}{2}$$
 = 0.01 M

No. of molecules in one molar solution =  $6.02 \times 10^{23}$ No. of molecules in 100 mL of 0.01 *M* oxalic acid solution

$$= \frac{0.01 \times 6.02 \times 10^{23}}{1000} \times 100$$
$$= 6.02 \times 10^{20}$$

**57.** How much water should be added to 50 mL of 0.1 N HCl in order to get 0.04 N solution?

- **58.** If 40 mL of 0.1 N KOH is mixed 60 mL of 0.05 N HCl, what will be the normality of the resulting solution? What will be the normality of salt formed after the reaction?
- 59. 1.26 g of a dibasic acid were dissolved in water and made up to 200 mL. 20 mL of this solution were completely neutralised by 10 mL of N/5 caustic soda solution. Calculate the equivalent mass and molecular mass of the acid.
- **60.** What will be the normality of solution obtained by mixing 20 mL of 0.5 N hydrochloric acid, 60 mL of 0.1 N sulphuric acid and 150 mL of 0.2 N nitric acid?
- 61. 3.0 g of a sample of impure ammonium chloride were boiled with excess of caustic soda solution. Ammonia gas so evolved was passed into 120 mL of N/2 H<sub>2</sub>SO<sub>4</sub>. 28 mL of N/2 NaOH were required to neutralise residual acid. Calculate the percentage of purity of the given sample of ammonium chloride.

| **Hint**: (120 - 28) mL N/2 H<sub>2</sub>SO<sub>4</sub> = 92 mL N/2 NH<sub>4</sub>Cl

- **62.** How much water should be added to 100 mL of 2.5 N H<sub>2</sub>SO<sub>4</sub> to make it normal solution?
- **63.** 2.20 g of an ammonium salt were boiled with 75 mL of *N* NaOH till the emission of ammonia gas ceased. The excess of unused NaOH solution required 70 mL of *N*/2 sulphuric acid for neutralisation. Calculate the percentage of ammonia in the salt.
- **64.** 3.45 g of a metallic carbonate were mixed with 240 mL of *N*/4 HCl. The excess acid was neutralised by 50 mL of *N*/5 KOH solution. Calculate the equivalent mass of the metal. [Hint: Equivalent mass of metal carbonate

$$= \frac{3.45 \times 4 \times 1000}{200} = 69$$
Equivalent mass of metal = 69 - eq. mass of carbonate =  $(69 - 30) = 39$ ]

- **65.** (a) 2 g of a metal carbonate were dissolved in 50 mL of *N* HCl. 100 mL of 0.1 *N* NaOH were required to neutralise the resultant solution. Calculate the equivalent mass of the metal carbonate.
  - (b) How much water should be added to 75 mL of 3 N HCl to make it a normal solution?
- 66. Upon mixing 45.0 mL of 0.25 *M* lead nitrate solution with 25 mL of 0.1 *M* chromic sulphate solution, precipitation of lead sulphate takes place. How many moles of lead sulphate are formed? Also calculate the molar concentrations of the species left behind in the final solution. Assume that lead sulphate is completely insoluble. [I.I.T. 1993]

[Hint: The reaction is:

$$3Pb(NO_3)_2 + Cr_2(SO_4)_3 \longrightarrow 3PbSO_4 + 2Cr(NO_3)_3$$
  
3 moles 1 mole 3 moles 2 moles  
No. of moles of  $Pb(NO_3)_2 = 45 \times 10^{-3} \times 0.25$   
=  $11.25 \times 10^{-3}$  mole

No. of moles of  $Cr_2(SO_4)_3 = 25 \times 10^{-3} \times 0.1 = 2.5 \times 10^{-3}$  mole Thus,  $Cr_2(SO_4)_3$  has limiting concentration. It shall be consumed fully and the number of moles of lead sulphate produced will be

$$= 3 \times 2.5 \times 10^{-3} = 7.5 \times 10^{-3} \text{ mole}$$
No. of moles of lead nitrate left =  $11.25 \times 10^{-3} - 7.5 \times 10^{-3}$   
=  $3.75 \times 10^{-3}$  mole  
Total volume =  $(45.0 + 25.0) = 70$  mL or  $70 \times 10^{-3}$  litre

Molarity = 
$$\frac{3.75 \times 10^{-3}}{70 \times 10^{-3}}$$
 = 0.0536 *M*  
No. of moles of Cr(NO<sub>3</sub>)<sub>3</sub> formed = 2 × 2.5 × 10<sup>-3</sup>

of moles of Cr(NO<sub>3</sub>)<sub>3</sub> formed = 
$$2 \times 2.5 \times 10^{-3}$$
  
=  $5 \times 10^{-3}$  mole  
Molarity =  $\frac{5 \times 10^{-3}}{70 \times 10^{-3}}$  = 0.0714 M

Pb(NO<sub>3</sub>)<sub>2</sub> and Cr(NO<sub>3</sub>)<sub>3</sub> will be present in solution in ionic form.

Thus, 
$$[Pb^{2+}] = 0.0536 M$$

$$[Cr^{3+}] = 0.0714 M$$

$$[NO_3^-] = (2 \times 0.0536) + (3 \times 0.0714)$$

$$= 0.3214 M$$

67. A sample of hydrazine sulphate (N<sub>2</sub>H<sub>6</sub>SO<sub>4</sub>) was dissolved in 250 mL of water. 10 mL of this solution was reacted with excess of ferric chloride solution and warmed to complete the reaction. Ferrous ions formed were estimated and it required 10 mL of 0.04 *M* potassium permanganate solution. Estimate the amount of hydrazine sulphate dissolved in 250 mL of the solution. Reactions:

$$4Fe^{3+} + N_2H_4 \longrightarrow N_2 + 4Fe^{2+} + 4H^+ 
MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O 
[M.L.N.R. 1993]$$

[Hint: See Example 34]

**68.** In an ore the only oxidisable material is  $Sn^{2+}$ . This ore is titrated with a dichromate solution containing 2.5 g K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in 0.50 litre. A 0.40 g of sample of the ore required 10.0 cm<sup>3</sup> of the titrant to reach equivalent point. Calculate the percentage of tin in ore. (K = 39.1, Cr = 52, Sn = 118.7)

[Roorkee 1993]

[Hint: Mol. mass of 
$$K_2Cr_2O_7 = 2 \times 39.1 + 2 \times 52 + 7 \times 16$$
  
=  $78.2 + 104.0 + 112.0$   
=  $294.2$   
Eq. mass of  $K_2Cr_2O_7 = \frac{294.2}{6} = 49.03$ 

Normality of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution 
$$=\frac{2.5}{49.03} \times \frac{1000}{500} = \frac{5}{49.03} N$$

10 mL
$$\frac{5}{49.03}$$
 N K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> = 10 mL $\frac{5}{49.03}$  N stannous ion

Eq. mass of 
$$\text{Sn}^{2+} = \frac{118.7}{2} = 59.35$$

Amount of Sn in the sample = 
$$\frac{5}{49.03} \times \frac{59.35}{1000} \times 10$$
  
= 0.0605 g

Percentage of Sn in the ore 
$$= \frac{0.0605}{0.40} \times 100 = 15.125$$
]

- 69. 2.26 g of impure ammonium chloride were boiled with 100 mL of N NaOH solution till no more ammonia was given off. The excess of NaOH solution left over required 30 mL 2 N H<sub>2</sub>SO<sub>4</sub> for neutralisation. Calculate the percentage purity of the salt. [H = 1; N = 14; O = 16; Na = 23; S = 32; Cl = 35.5]
- **70.** Metallic tin in the presence of HCl is oxidised by K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution to stannic chloride. What volume of decinormal dichromate solution would be reduced by 1 g of Sn?

[M.L.N.R. 1994]

[Hint: 
$$3Sn + 2K_2Cr_2O_7 + 28HCl \longrightarrow 3SnCl_4 + 4KCl + 4CrCl_3  $3 \times 118.7 \text{ g} \quad 2 \times 294 \text{ g} \quad + 14H_2O$$$

$$K_2Cr_2O_7$$
 required for 1 g of  $Sn = \frac{2 \times 294}{3 \times 118.7} = 1.65$  g]

71. A sample containing 0.4775 g of (NH<sub>4</sub>)<sub>2</sub>C<sub>2</sub>O<sub>4</sub> and inert materials was dissolved in water and made strongly alkaline with KOH which converted NH<sub>4</sub> to NH<sub>3</sub>. The liberated ammonia was distilled into exactly 50.0 mL of 0.05035 M H<sub>2</sub>SO<sub>4</sub>. The excess H<sub>2</sub>SO<sub>4</sub> was back titrated with 11.3 mL of 0.1214 M NaOH. Calculate: (i) percentage of N, (ii) percentage of  $(NH_4)_2C_2O_4$ .

[At. mass of nitrogen = 14.0078; Mol. mass of  $(NH_4)_2C_2O_4$ =124.101[M.L.N.R. 1994]

[**Hint**: 11.3 mL 0.1214 M NaOH = 11.3 mL 0.1214 N NaOH  $\equiv 11.3 \text{ mL } 0.1214 \text{ N } \text{H}_2\text{SO}_4 = 1.3718 \text{ meq. } \text{H}_2\text{SO}_4$ 

H<sub>2</sub>SO<sub>4</sub> acid used for neutralisation of NH<sub>2</sub>

$$= (5.035 - 1.3718) = 3.663 \text{ meq.}$$
  
 $= 3.663 \text{ meq. NH}_3$ 

Amount of ammonium oxalate =  $3.663 \times 10^{-3} \times \text{Eq.}$  mass

= 
$$3.663 \times 10^{-3} \times \frac{124.10}{2}$$
  
=  $0.2273$  g]

72. A 0.5 g sample containing MnO<sub>2</sub> is treated with HCl liberating Cl<sub>2</sub>. The Cl<sub>2</sub> is passed into a solution of KI and 30.0 cm<sup>3</sup> of 0.1 M Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> are required to titrate the liberated iodine. Calculate the percentage of MnO<sub>2</sub> in the sample.

[Roorkee 1994]

[Hint: 30.0 mL 0.1 
$$M$$
 Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 30.0 mL 0.1  $N$  Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>  
= 30.0 mL 0.1  $N$  Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>  
= 30.0 mL 0.1  $N$  Cl<sub>2</sub>  
= 30.0 mL 0.1  $N$  MnO<sub>2</sub>  
Amount of MnO<sub>2</sub> present =  $\frac{N \times E \times V}{1000}$   
=  $\frac{1}{10} \times \frac{87}{2} \times \frac{30}{1000}$   
% MnO<sub>2</sub> =  $\frac{87 \times 30 \times 100}{10 \times 2 \times 1000 \times 0.5} = 26.1$ ]

- 73. 5.3 g of a diacidic base was dissolved in water and made up to 1000 mL. 20 mL of this solution was completely neutralised by 24 mL of N/12 hydrochloric acid solution. Calculate the equivalent mass and molecular mass of the base.
- 74. 3.2 g of a mixture of calcium carbonate and sodium chloride was dissolved in 100 mL of 1.02 N HCl. After the reaction the solution was filtered and after separating the precipitate the volume was raised to 200 mL. 20 mL of this solution required 25 mL N/5 caustic soda solution for neutralisation. Find out the percentage of calcium carbonate in the mixture.
- 75. 4 g of a mixture of Na<sub>2</sub>SO<sub>4</sub> and anhydrous Na<sub>2</sub>CO<sub>3</sub> were dissolved in pure water and volume made up to 250 mL. 20 mL of this solution required 25 mL of N/5 H<sub>2</sub>SO<sub>4</sub> for complete neutralisation. Calculate the percentage composition of the mixture.
- **76.** A 1.2 g mixture of Na<sub>2</sub>CO<sub>3</sub> and K<sub>2</sub>CO<sub>3</sub> was dissolved in water to form 100 cm<sup>3</sup> of a solution. 20 cm<sup>3</sup> of this solution required 40 cm<sup>3</sup> of 0.1 N·HCl for neutralisation. Calculate the mass of Na<sub>2</sub>CO<sub>3</sub> and K<sub>2</sub>CO<sub>3</sub> in the mixture. [Roorkee 1997]

77. One litre of a mixture of  $O_2$  and  $O_3$  at NTP was allowed to react with an excess of acidified solution of KI. The iodine liberated required 40 mL of M/10 sodium thiosulphate solution for titration. What is the weight per cent of ozone in the mixture? Ultraviolet radiation of wavelength 300 nm can decompose ozone. Assuming that one photon can decompose one ozone molecule, how many photons would have been required for the complete decomposition of ozone in the original mixture? [L.I.T. 1997]

**[Hint:** Let the total moles of  $O_2$  and  $O_3$  in the mixture be n.

Applying 
$$PV = nRT$$

$$1 \times 1 = n \times 0.0821 \times 273$$

$$n = 0.044 \text{ mole}$$

$$Moles of O_3 = \text{moles of } I_2$$

$$= 1/2 \text{ moles of } Na_2S_2O_3$$

$$= \frac{1}{2} \times \frac{1}{10} \times \frac{40}{1000}$$

$$= 0.002 \text{ mole}$$

Moles of 
$$O_2$$
 in the mixture = 0.044 - 0.002 = 0.042 mole

Mass of  $O_2$  = 0.042 × 32 = 1.344 g

Mass of  $O_3$  = 0.002 × 48 = 0.096 g

%  $O_3$  =  $\frac{0.096}{1.44}$  × 100 = 6.6

No. of photons required to decompose 0.002 mole of ozone

 $= 0.002 \times 6.02 \times 10^{23} = 1.204 \times 10^{21}$ 

- **78.** 20 mL of a solution containing 0.2 g of impure sample of  $H_2O_2$ reacts with 0.316 g of KMnO<sub>4</sub> (acidic). Calculate:
  - (a) Purity of H<sub>2</sub>O<sub>2</sub>
  - (b) Volume of dry O<sub>2</sub> evolved at 27°C and 750 mm pressure.
- 79. Five gram of copper alloy was dissolved in a litre of dilute H<sub>2</sub>SO<sub>4</sub>. 20 mL of this solution was titrated iodometrically and it required 20 mL of a hypo solution. 20 mL of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> which contained 2.4 g per litre, in presence of H<sub>2</sub>SO<sub>4</sub> and excess of KI, required 30 mL of the same hypo solution. Calculate the % purity of copper in the alloy.
- How many millilitres of 0.5 M H<sub>2</sub>SO<sub>4</sub> are needed to dissolve 0.5 g of copper (II) carbonate? [I.I.T. 1999]

[Hint: 
$$N_1V_1 = N_2V_2$$
]

$$N_1$$
 = Normality of H<sub>2</sub>SO<sub>4</sub> = 0.5 × 2 = 1 N

$$V_1$$
 = Vol. of H<sub>2</sub>SO<sub>4</sub>

$$N_2$$
 = Normality of copper (II) carbonate =  $\frac{0.5 \times 2}{123.5} N$ 

 $V_2$  = Volume of copper (II) carbonate = 1000 mL

Thus, 
$$1.0 \times V_1 = \frac{0.5 \times 2}{123.5} \times 1000$$
  
or  $V_1 = 8.09 \text{ mL}$ 

81. An aqueous solution containing 0.10 g KIO<sub>3</sub> (formula weight = 214.0) was treated with an excess of KI solution. The solution was acidified with HCl. The liberated iodine consumed 45.0 mL of thiosulphate solution to decolourise the blue starch-iodine complex. Calculate the molarity of the sodium thiosulphate solution.

[Hint: 
$$2KIO_3 + 10KI + 12HCI \longrightarrow 12KC1 + 6I_2 + 6H_2O$$
  
 $[2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6] \times 6$ 

$$2KIO_3 + 10KI + 12Na_2S_2O_3 + 12HCl \longrightarrow 12KCl + 12NaI \\ 2 \ mole \qquad \qquad 12 \ mole \qquad \qquad + 6Na_2S_4O_6 + 6H_2O$$

No. of moles of KIO<sub>3</sub> = 
$$\frac{0.10}{214}$$
  
No. of moles of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> required for  $\frac{0.10}{214}$  mole of KIO<sub>3</sub> =  $\frac{12}{2} \times \frac{0.10}{214} = \frac{0.60}{214}$ 

Molarity of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 
$$\frac{0.6}{214} \times \frac{1000}{45} = 0.0623 M$$

82. A sample of magnesium was burnt in air to give mixture of MgO and Mg<sub>3</sub>N<sub>2</sub>. The ash was dissolved in 60 meq. of HCl and the resulting solution back titrated with NaOH. 12 meq. of NaOH were required to reach the end point. An excess of NaOH was then added and the solution distilled. The ammonia released was then trapped in 10 meg. of second acid solution. Back titration of this acid solution required 6 meq. of the base. Calculate percentage magnesium burnt to the nitride. [Roorkee 1998]

[Hint: Let moles of Mg used for MgO and Mg<sub>3</sub>N<sub>2</sub> are x and y respectively.

$$2Mg + O_2 \longrightarrow 2MgO$$

$$3Mg + N_2 \longrightarrow Mg_3N_2$$
Moles of MgO =  $x$ , Moles of Mg<sub>3</sub>N<sub>2</sub> =  $y/3$ 
MgO + 2HCl  $\longrightarrow$  MgCl<sub>2</sub> + H<sub>2</sub>O
Mg<sub>3</sub>N<sub>2</sub> + 8HCl  $\longrightarrow$  3MgCl<sub>2</sub> + 2NH<sub>4</sub>Cl

Solution will contain x moles of MgCl<sub>2</sub> and 2y/3 moles of NH<sub>4</sub>Cl.

Moles of HCl used = 2x + 8y/3 for MgO and Mg<sub>3</sub>N<sub>2</sub>

$$2x + \frac{8y}{3} = 60 - 12 = 48$$
 ... (i)

Moles of NH<sub>4</sub>Cl formed = moles of NH<sub>3</sub>

= moles of HCl used to absorb NH<sub>3</sub>  

$$2y/3 = 4$$
  
 $y = 6$ 

From eq. (i) 
$$2x + \frac{8 \times 6}{3} = 48$$
$$x = 16$$

$$x = 16$$
  
% Mg used for Mg<sub>3</sub>N<sub>2</sub> =  $\left(\frac{6}{6+16}\right) \times 100 = 27.27\%$ 

**83.** A sample of hard water contains 96 ppm of  $SO_4^{2-}$  and 183 ppm of HCO<sub>3</sub>, with Ca<sup>2+</sup> as the only cation. How many moles of CaO will be required to remove HCO<sub>3</sub> from 1000 kg of this water? If 1000 kg of this water is treated with the amount of CaO calculated above, what will be the concentration (in ppm) of residual Ca<sup>2+</sup> ions? (Assume CaCO<sub>3</sub> to be completely insoluble in water). If the Ca<sup>2+</sup> ions in one litre of the treated water are completely exchanged with hydrogen ions, what will be its pH?

(One ppm means one part of the substance in one million parts of water.) [LLT. May 1997]

- **84.** Gastric juice contains 3 g of HCl per litre. If a person produces 2.5 litre of gastric juice per day, how many antacid tablets each containing 400 mL of Al(OH)<sub>3</sub> are needed to neutralize all the HCl produced in one day? [Dhanbad 1991]
- 85. Zinc can be determined volumetrically by the precipitation reactions.

$$3Zn^{2+} + 2K_4[Fe(CN)_6] \longrightarrow K_2Zn_3[Fe(CN)_6] + 6K^+$$

A sample of Zn ore weighing 1.5432 g was prepared for reaction and required 34.68 mL of 0.1043 M K<sub>4</sub>[Fe(CN)<sub>6</sub>] for titration. What is percentage of zinc in the ore?

- A mixture of KOH and Na<sub>2</sub>CO<sub>3</sub> solution required 15 mL of N/20 HCl using phenolphthalein as indicator. The same amount of alkali mixture when titrated using methyl orange as indicator required 25 mL of same acid, Calculate amount of KOH and Na<sub>2</sub>CO<sub>3</sub> present in solution.
- 87. 1000 mL O<sub>2</sub> at NTP was passed through Siemen's ozonizer so that the volume is reduced to 888 mL at same condition. Ozonized oxygen is passed through KI solution. Liberated  $I_2$  was titrated with 0.05 N hypo. Calculate volume of hypo used.
- 88. 1 g of an alloy of copper was dissolved in dilute H<sub>2</sub>SO<sub>4</sub> and solution made up to 1 litre. To 20 mL of this solution excess of KI was added, liberated iodine required 10 mL of a sodium thiosulphate solution for complete titration. In another experiment 2.45 g of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> was dissolved in a litre. Excess of KI was added to 20 mL of this solution; liberated iodine required 50 mL stock of same Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> solution. Calculate amount of copper in the alloy.

(Given, equivalent mass of hypo = 158; equivalent mass of  $K_2Cr_2O_7 = 49$ 

- 89. 30 mL of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> liberated iodine from KI solution when the iodine was titrated with hypo solution (N/20), the titre value was 45 mL. Find the concentration of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> in g per litre.
- Excess of KI and dil. H<sub>2</sub>SO<sub>4</sub> were mixed in 50 mL H<sub>2</sub>O<sub>2</sub>. The liberated I<sub>2</sub> required 20 mL of 0.1 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Find out the strength of H<sub>2</sub>O<sub>2</sub> in g/litre.
- 91. 0.32 g sample of KI (impure) was dissolved in 1.1 millimoles of K<sub>2</sub>CrO<sub>4</sub> and 25 mL of 5 N H<sub>2</sub>SO<sub>4</sub>. Iodine formed was expelled off by boiling and the solution is now mixed with excess of pure KI and I2 liberated again which on titration required 14 mL of 0.1 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>. Calculate % purity of original KI sample.

$$2CrO_4^{2-} + 2H^{+} \longrightarrow Cr_2O_7^{2-} + H_2O$$
  
 $Cr_2O_7^{2-} + 6I^{-} + 14H^{+} \longrightarrow 2Cr^{3+} + 3I_2 + 7H_2O$ 

**92.** 6 g sample of  $(Fe_3O_4 + Fe_2O_3)$  mixture and an inert material was treated with excess of aqueous KI which reduces all Fe<sup>3+</sup> to Fe<sup>2+</sup> ion. The resulting solution was diluted to 50 mL. 10 mL of the diluted solution titrated with 5.5 mL of 1 M Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> to react with all iodine. The I<sub>2</sub> from another 25 mL sample was extracted after which the Fe<sup>2+</sup> was titrated with 3.2 mL of 1 M MnO<sub>4</sub> in H<sub>2</sub>SO<sub>4</sub> solution. Calculate percentage of Fe<sub>2</sub>O<sub>3</sub> and Fe<sub>3</sub>O<sub>4</sub> in the mixture.

[Hint: Reactions involved are:

- (1)  $Fe_3O_4 + 2KI + 4H_2SO_4 \longrightarrow 3FeSO_4 + K_2SO_4 + 4H_2O + I_2$
- (2)  $Fe_2O_3 + 2KI + 3H_2SO_4 \longrightarrow 2FeSO_4 + K_2SO_4 + 3H_2O + I_2$
- $I_2 + 2S_2O_3^{2-} \longrightarrow 2\Gamma + S_4O_6^{2-}$ (3)
- (4)  $MnO_4 + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2Ol^+$
- 93. 25 mŁ H<sub>2</sub>O<sub>2</sub> were added to excess of acidified solution of KI. The iodine so liberated required 20 mL of 0.1 N sodium

thiosulphate for titration. Calculate the strength in terms of normality, percentage and volume. [M.L.N.R. 1996]

- 94. Cl<sub>2</sub> gas can be produced in the lab by the reaction,  $K_2Cr_2O_7 + 14HCl \longrightarrow 2KCl + 2CrCl_3 + 7H_2O + 3Cl_2$ If a 6.13 g sample that is 96% K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is allowed to react
  - with 320 mL of HCl solution having density 1.15 g/mL and containing 30% by mass of HCl, what mass of Cl<sub>2</sub> is generated?
- 95. What is the weight in grams of available O<sub>2</sub> per litre from a solution of H<sub>2</sub>O<sub>2</sub>. 10 mL of which when titrated with N/20 KMnO<sub>4</sub> solution required 25 mL for the reaction,

$$2KMnO_4 + 5H_2O_2 + 4H_2SO_4 \longrightarrow$$
  
 $5O_2 + 8H_2O + 2KHSO_4 + 2MnSO_4$ 

96. A quantity of KMnO<sub>4</sub> was boiled with HCl and the gas evolved was led into a solution of KI. When the reaction was complete, the I2 liberated was titrated with a solution of hypo containing 124 g of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O per litre. It was found that exactly 60 mL were required to decolourise the solution of I<sub>2</sub>. What weight of KMnO<sub>4</sub> was used?

- 97: 0.5 g of a sample of bleaching powder was suspended in water and excess K1 is added. On acidifying with dil. H<sub>2</sub>SO<sub>4</sub>, I<sub>2</sub> was liberated which required 50 mL of N/10 hypo (Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O). Calculate percentage of available Cl<sub>2</sub> in bleaching powder.
- 98. 1.2 g of a sample of CaOCl<sub>2</sub> were suspended in water made upto 100 mL. 25 mL of this solution was treated with KI and the 1<sub>2</sub> liberated corresponded to 10 mL of N/25 hypo. Calculate percentage of Cl<sub>2</sub> available in CaOCl<sub>2</sub>.
- 99. 1.6 g of pyrolusite was treated with 60 mL of normal oxalic acid and some H2SO4. The oxalic acid left undecomposed was made upto 250 mL, 25 mL of this solution required 32 mL of 0.1 N potassium permanganate (KMnO<sub>4</sub>). Calculate the percentage of pure MnO<sub>2</sub> in pyrolusite.
- 100. A sample of pyrolusite weighing 0.5 g is distilled with conc. HCl. The evolved Cl<sub>2</sub> when passed through a solution of KI liberates sufficient I<sub>2</sub> to react with 125 mL of N/12.5 hypo (Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O). Calculate the percentage of MnO<sub>2</sub> in pyrolusite.

## ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. A 5 molar solution of H<sub>2</sub>SO<sub>4</sub> is diluted from 1 L to 10 L. What is the normality of the solution? [M.H.C.E.T. 2005]
  - (a) 0.25 N

(b) 1 N

(c) 2N

(d) 7N

Ans. (b)

|Hint:

 $N_1V_1$ 

Normality = Molarity × Basicity of acid

$$= 5 \times 2 = 10$$

(Before dilution) (After dilution)

$$10 \times 1 = N_2 \times 10$$

$$N_2 = 1 N_1$$

2. A solution contains  $1.2046 \times 10^{24}$  hydrochloric acid molecules in one dm<sup>3</sup> of the solution. The normality of the solution is:

[H.C.E.T. 2005]

(a) 6N

(b) 2 N

(c) 4 N

(d) 8 N

Ans. (b) | Hint: Number of moles of HCl dissolved in 1 litre

$$=\frac{1.2046\times10^{24}}{6.023\times10^{23}}=2$$

Molarity = 2 M٠.

Normality = Molarity × Basicity of acid

 $= 2 \times 1 = 2 N1$ 

3. What volume of NaOH solution (0.1 N) is added to 40 mL of NaOH(0.1N) which is neutralized by 50 mL of HCI (0.2 N)?

[P.M.T. (Punjab) 2005]

(a) 80 mL

(b) 60 mL

(c) 40 mL

(d) 90 mL

Ans. (b) |Hint:

 $N_1V_1$  (acid) =  $N_2V_2$  (base)

$$0.2 \times 50 = N_2 V_2$$
 (base)

$$0.2 \times 50 = 0.1 \times V_2$$

or 
$$V_2 = \frac{10}{0.1} = 100 \text{ mL}$$

Volume of solution added = 100 - 40 = 60 mL]

- 4. The normality of a mixture obtained by mixing 100 mL 0.2 M H<sub>2</sub>SO<sub>4</sub> and 100 mL 0.2 M NaOH is:
  - (a) 0.2 N

(b) 0.01 N

(c) 0.1 N

(d) 0.3 N

Ans. (c)

Hint:

Normality of  $H_2SO_4 = Molarity \times Basicity$  $= 0.2 \times 2 = 0.4$ 

Normality of  $NaOH = Molarity \times Acidity$ 

 $= 0.2 \times 1 = 0.2$ 

 $N_1V_1(H_2SO_4) - N_2V_2 \text{ (NaOH)} = N_{Resultant}(V_1 + V_2)$  $0.4 \times 100 - 0.2 \times 100 = N_{\text{Resultant}}(200)$ 

 $N_{\text{Resultant}} = 0.1 \text{ N}$ 

- 5. 35.4 mL of HCl is required for the neutralization of a solution containing 0.275 g of sodium hydroxide. The normality of hydrochloric acid is:
  - (a) 0.97 N

(b) 0.142 N

(c) 0.194 N

(d) 0.244 N

Ans. (c)

[**Hint :** Number of equivalents of NaOH =  $\frac{IVIADD}{Equivalent mass}$  $=\frac{0.275}{40}=6.875\times10^{-3}$ 

Number of equivalents of HCl = Number of equivalents of NaOH

$$\frac{NV}{1000} = 6.875 \times 10^{-3}$$
$$\frac{N \times 35.4}{1000} = 6.875 \times 10^{-3}$$
$$N = 0.1941$$

6. 15 volume sample of an H<sub>2</sub>O<sub>2</sub> solution is equivalent to:

(a) 5.30 N (b) 1.77 N

(c) 2.68 N

(d) 7.5 N

Ans. (c)

**Hint:** Volume strength of  $H_2O_2 = N \times 5.6$ 

$$15 = N \times 5.6$$

N = 2.681

7. KMnO<sub>4</sub> reacts with oxalic acid according to the equation,

$$2MnO_4^- + 5C_2O_4^{2-} + 16H^+ \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$$

Here, 20 mL of 0.1 M KMnO<sub>4</sub> is equivalent to:

- (a)  $120 \text{ mL of } 0.25 M \text{ H}_2\text{C}_2\text{O}_4$  (b)  $150 \text{ mL of } 0.1 M \text{ H}_2\text{C}_2\text{O}_4$
- (c)  $50 \text{ mL of } 0.10 \text{ M H}_2\text{C}_2\text{O}_4$  (d)  $50 \text{ mL of } 0.20 \text{ M H}_2\text{C}_2\text{O}_4$ Ans. (c)

[**Hint**: 
$$\frac{M_1V_1}{n_1}$$
(MnO<sub>4</sub><sup>-</sup>) =  $\frac{M_2V_2}{n_2}$ (H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>)  
For MnO<sub>4</sub><sup>-</sup>,  $\frac{M_1V_1}{n_1}$  =  $\frac{0.1 \times 20}{2}$  = 1  
For H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>,  $\frac{M_2V_2}{n_2}$  =  $\frac{50 \times 0.1}{5}$  = 1]

- **8.** 100 mL of *N*/5 NaOH will neutralize:
  - (a)  $0.06184 \text{ g of } H_3BO_3$
- (b)  $0.1855 \text{ g of } H_3BO_3$
- (c) 1.2368 g of H<sub>3</sub>BO<sub>3</sub>
- (d) 0.03092 g of H<sub>3</sub>BO<sub>3</sub>

Ans. (c)

**Hint:** Number of equivalents of  $H_3BO_3 = Number of equivalents$ 

$$= \frac{NV}{1000} = \frac{\frac{1}{5} \times 100}{1000} = 0.02 \qquad \dots (1)$$

Number of equivalents of  $H_3BO_3 = \frac{Praction}{Equivalent mass}$ 

$$\frac{1.2368}{62} = 0.0199 \approx 0.02$$
 ... (2)

9. What volume of 0.1 M H<sub>2</sub>SO<sub>4</sub> will be required to produce 17 g of H<sub>2</sub>S by the reaction,

$$5H_2SO_4 + 8Nal \longrightarrow 4Na_2SO_4 + 4I_2 + H_2S + 4H_2O$$
?

(a) 70 L

(b) 50 L

(c) 25 L

(d) 5L

Ans. (c)

|Hint: : 34 g H<sub>2</sub>S is formed by 5 mole of H<sub>2</sub>SO<sub>4</sub> :. 17 g H<sub>2</sub>S will be formed by 2.5 mole of H<sub>2</sub>SO<sub>4</sub>

Number of moles = 
$$\frac{MV}{1000}$$
  
2.5 =  $\frac{0.1 \times 1}{1000}$ 

or

$$V = 25000 \text{ mL} = 25 \text{ L}$$

**10.** 50 mL of a solution of Na<sub>2</sub>CO<sub>3</sub> neutralizes 49.35 mL of 4 *N* HCl. The reaction is represented as

$$CO_3^{2-} + 2H^+ \longrightarrow CO_2 + H_2O$$

The density of this  $Na_2CO_3$  solution is 1.25 g mL<sup>-1</sup>. The percentage of  $Na_2CO_3$  in it is:

(a) 47.7

(b) 37.7

(c) 26.7

(d) 16.7

Ans. (d)

$$\frac{M_1 V_1}{n_1} (\text{CO}_3^{2-}) = \frac{M_2 V_2}{n_2} (\text{H}^+)$$

[Hint:

 $n_1$  and  $n_2$  are corresponding coefficients in the balanced equation,

$$\frac{M_1 \times 50}{1} = \frac{4 \times 49.35}{2}$$

$$M_1 = 1.974$$

 $M = \frac{x \times d \times 10}{m}$ 

 $\frac{m_{B}}{m_{B}}$ Where, x = Percentage by mass of solute

d =Density of solution  $m_B =$ Molar mass of solution

$$1.974 = \frac{x \times 1.25 \times 10}{106}$$
$$x = 16.7$$

11. A 0.492 g of KH<sub>2</sub>PO<sub>4</sub> is titrated against a solution of 0.112 M NaOH. The volume of the base required to do this is 25.6 mL. The reaction involved is,

$$KH_2PO_4 + NaOH \longrightarrow NaKHPO_4 + H_2O$$

The percentage purity of KH<sub>2</sub>PO<sub>4</sub> is:

(a) 88.45

(b) 78.42

(c) 79.06

(d) 46.32

Ans. (c)

**Hint:** Number of moles of  $KH_2PO_4 = Number$  of moles of NaOH

$$= \frac{MV}{1000} = \frac{0.112 \times 25.6}{1000}$$

$$= 2.8672 \times 10^{-3}$$
Mass of KH<sub>2</sub>PO<sub>4</sub> = 2.8672 × 10<sup>-3</sup> × 136
$$= 0.389 \text{ g}$$

Percentage purity of  $KH_2PO_4 = \frac{0.389}{0.492} \times 100 \approx 79.06$ 

- 12. When 3.92 g L<sup>-1</sup> of sample of Mohr's salt reacts completely with 50 mL N/10 KMnO<sub>4</sub> solution. The percentage purity of the sample of Mohr's salt is:
  - (a) 50

(b) 70

(c) 37

(d) 40

Ans. (a)

[Hint:  $N_1V_1$ (Mohr's salt) =  $N_2V_2$ (KMnO<sub>4</sub>)

$$N_1 \times 1000 = 1/10 \times 50$$
  
 $N_1 = 0.005$ 

Strength of Mohr's salt [FeSO<sub>4</sub>(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>·6H<sub>2</sub>O]

$$= 0.005 \times 392 = 1.96 \text{ g}$$

Percentage purity of Mohr's salt sample =  $\frac{1.96}{3.92} \times 100$ = 50%1

- **13.** A solution of 10 mL of  $M/10 \, \text{FeSO}_4$  was titrated with KMnO<sub>4</sub> solution in acidic medium, the amount of KMnO<sub>4</sub> used will be:
  - (a) 10 mL of 0.5 M
- (b) 10 mL of 0.1 M
- (c) 5 mL of 0.1 M
- (d) 10 mL of 0.02 M

Ans. (d)

[Hint: The reaction involved is,

$$2KMnO_4 + 8H_2SO_4 + 10FeSO_4 \longrightarrow 5Fe_2(SO_4)_3 + 2MnSO_4 + K_2SO_4 + 8H_2O$$

$$\frac{M_1V_1}{n_1}$$
 (KMnO<sub>4</sub>) =  $\frac{M_2V_2}{n_2}$  (FeSO<sub>4</sub>)

$$\frac{M_2V_2}{n_2}$$
 (FeSO<sub>4</sub>) =  $\frac{0.1 \times 10}{10}$  = 0.1

$$\frac{M_1V_1}{n_1}$$
 (KMnO<sub>4</sub>) =  $\frac{0.02 \times 10}{2}$  = 0.1 ]

- 14. An aqueous solution of 6.3 g of oxalic acid dihydrate is made upto 250 mL. The volume of 0.1 N NaOH required to completely neutralise 10 mL of this solution is:
  - (a) 40 mL

- (b) 20 mL
- (c) 100 mL
- (d) 400 mL

**Ans**: (a)

[Hint: 
$$N_{\text{oxalic acid}} = \frac{w_B \times 1000}{E_B \times V}$$

$$= \frac{6.3 \times 1000}{63 \times 250} = 0.4$$

$$N_1V_1$$
 (oxalic acid) =  $N_2V_2$  (NaOH)

$$0.4\times 10=0.1\times V_2$$

$$V_2 = 40 \text{ mL}$$

- 15. The formula mass of an acid is 82 amu. In a titration, 100 cm<sup>3</sup> of a solution of this acid containing 39 g of the acid per litre was completely neutralized by 95 cm<sup>3</sup> of aqueous solution of NaOH containing 40 g NaOH per litre of solution. What is the basicity of the acid?
  - (a) 4

(b) 2

(c) 1

(d) 0

**Ans**: (b)

Hint:

$$N_{\text{NaOH}} = 1$$
 (: 40 g/litre = 1 N NaOH)  
 $N_1 V_1 (\text{acid}) = N_2 \dot{V}_2 (\text{NaOH})$ 

$$N_1 \times 100 = 1 \times 95$$

$$N_1 = 0.95$$

$$\mathbf{v}_1 = 0.93$$

$$N = \frac{w_B \times 1000}{E_B \times V}$$

$$0.95 = \frac{39 \times 1000}{E_B \times 1000}$$

$$E_{R} = 41$$

Equivalent mass =  $\frac{\text{Molecular mass}}{\text{Basicity}}$ 

$$41 = \frac{82}{\text{Basicity}}$$

# **OBJECTIVE QUESTIONS**

Note: Choose the correct answer(s) out of given alternatives for each question.

1.	A normal solution:		(a) equal to its mol. mass $\square$ (b) 1/3 of its mol. mass $\square$	J
	(a) contains one gram equivalent mass of the substance in		(c) $1/6$ of its mol. mass $\square$ (d) $1/5$ of its mol. mass $\square$	J
	one litre solution $\Box$	11.	In the reaction,	
	(b) contains one gram molecular mass of the substance in		$I_2 + 2S_2O_3^{2-} \longrightarrow 2I^- + S_4O_6^{2-}$	
	one litre solution		equivalent mass of iodine is: [M.P. (P.M.T.) 2004	η
	(c) contains one gram equivalent mass of the substance in		(a) equal to its molecular mass	Ī
	100 mL of the solution		(b) 2/3 the molecular mass	]
^	(d) is that whose concentration is known		(c) 2/9 the molecular mass	]
2.	Which one of the following is a standard solution?		(d) twice the molecular mass	]_
	(a) it contains one gram equivalent mass of the substance	12.	A molal solution is one that contains one mole of the solut	e
	in one litre solution  (b) its strength is accurately known		in:	
			(a) 1000 g of the solvent	J
	()	1		]
	(d) a solution which has been prepared from pure substance			
2	The medianter mass of H DO is 92 Its assistant mass if		(d) 22.4 litre of the solvent	
3.	The molecular mass of H <sub>3</sub> PO <sub>3</sub> is 82. Its equivalent mass if	13.	In alkaline conditions, KMnO <sub>4</sub> reacts as follows,	
	it is completely neutralised, is:  (a) 82		$2KMnO_4 + 2KOH \longrightarrow 2K_2MnO_4 + H_2O + [O]$	
	(a) $62$		Therefore, its equivalent mass will be:	
4.	The molecular mass of Mohr's salt, $FeSO_4(NH_4)_2SO_4\cdot 6H_2O$ ,		(a) 31.6	٦
т.	is 392. Its equivalent mass is:			_
	(a) 196	14.		_
	(c) 98.0	- "	the best indicator to be used is:	-,
5.	$\operatorname{Cr}_2\operatorname{O}_7^{2-} \xrightarrow{\operatorname{H}^+} \operatorname{Cr}^{3+}$ equivalent mass of $\operatorname{Cr}_2\operatorname{O}_7^{2-}$ is:			
<i>J</i> ,				_
				_
	(a) $\frac{\text{mol. mass}}{3}$ $\square$ (b) $\frac{\text{mol. mass}}{6}$ $\square$		(-)	
	3	15.	For the preparation of a litre of $N/10$ solution of $H_2SO_4$ , w	/e
	(c) mol. mass $\square$ (d) $\frac{\text{mol. mass}}{4}$ $\square$		need:	*
6.	Amount of oxalic acid required to prepare 250 mL of N/10		4	]
	solution (Mol. mass of oxalic acid = 126) is:			
	(a) $1.5759 g$	16.	Molecular mass of a tribasic acid is M. Its equivalent mas	SS
	(c) $15.75  \text{g}$	1	will be:	
7.	Normality of 2% H <sub>2</sub> SO <sub>4</sub> solution by volume is nearly:		(a) $M/3$	
	(a) 2		(-)	
	(c) $0.2$ $\Box$ (d) $0.4$ $\Box$	17.	A solution containing Fe <sup>2+</sup> ions is titrated with KMnC	)4
8.	The equivalent mass of KMnO <sub>4</sub> in the following reaction is:		solution. Indicator used will be:	
	[J.E.E. (Orissa) 2010]		(a) phenolphthalein $\Box$ (b) methyl orange	
	$MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 5Fe^{3+} + 4H_2O$	İ	(-)	
	(a) $M/2$ $\Box$ (b) $M/3$ $\Box$	18.	If 200 mL of N/10 HCl were added to 1 g calcium carbonate	e,
	(c) $M/5$ $\square$ (d) $M/4$ $\square$		what would remain after the reaction?	
	[Hint: Change in oxidation number of Mn per molecule = $7 - 2$		(a) $CaCO_3$ $\Box$ (b) $HCl$	
	= 5,  Eq. mass = M/5]		(-)	
9.	When KMnO <sub>4</sub> is reduced with oxalic acid in acidic	19.	How many mL of 1 M H <sub>2</sub> SO <sub>4</sub> acid solution is required t	to
	medium, the oxidation number of Mn changes from:		neutralise 10 mL of 1 M NaOH?	
	(a) 7 to 4		(a) $5 \text{ mL}$	_
	(c) $7 \text{ to } 2$ $\square$ (d) $4 \text{ to } 2$ $\square$			
10.		20.	200 mL of 3 N HCl were mixed with 200 mL of 6 N H <sub>2</sub> SC	-
	$2BrO_3^- + 12H^+ + 10e \longrightarrow Br_2 + 6H_2O$		solution. The final normality of H <sub>2</sub> SO <sub>4</sub> in the resultan	nt
	the equivalent mass of sodium bromate is:	İ	solution will be:	

	(a) $9 N$ $\square$ (b) $3 N$		33.	In an experiment, 20 mL			
0.1	(c) $6N$ $\Box$ (d) $2N$					nal AgNO <sub>3</sub> solution. AgC	
21.	The volume of water to be added to 400 mL of N/8 HC	l to				of acid was titrated with	N/20
	make it exactly $N/12$ , is:			NaOH solution. The volu		•	
	(a) 400 mL			(a) 10 mL		(b) 20 mL	
22.	100 mL of 0.3 N HCl were mixed with 200 mL of 0.6 N H <sub>2</sub> :		24	(c) 30 mL		(d) 5mL	
22.	solution. The final normality of acid was:	304	34.	lodine solution is prepar			-
	(a) $0.4 N$ $\square$ (b) $0.5 N$			(a) NaOH (c) H <sub>2</sub> O		(b) Na <sub>2</sub> CO <sub>3</sub> (d) KI	
	(c) $0.6 N$		35	Which one of the follow			
23.	The molecular mass of NaOH is 40.50 mL of a solu			(a) oxalic acid		s not a primary standard: (b) sodium thiosulphate	
	containing 2 g of NaOH in 500 mL will require for comp			(c) sodium hydroxide		(d) potassium dichromat	
	neutralisation:		36.	Which one of the follow		• •	
	(a) 10 mL decinormal HCl			(a) KMnO <sub>4</sub>		(b) CuSO <sub>4</sub> -5H <sub>2</sub> O	
	(b) 20 mL decinormal HCl			(c) I <sub>2</sub>		(d) $H_2SO_4$	
	(c) 50 mL decinormal HCl		37.	When 10 mL of 10 M sol			1 M
	(d) 25 mL decinormal HCl			solution of NaOH are mi	xed,	the resulting solution will	be:
24.	50 g of a sample of NaOH required for complete neu			(a) acidic		(b) neutral	
	lisation, I litre N HCl. What is the percentage purity	/ of		(c) alkaline		(d) cannot be predicted	
	NaOH?		38.	1.0 g of a metal carbonat	e net	itralizes 200 mL of 0.1 N	HCI.
	(a) 80			The equivalent mass of t	he m	etal will be:	
	(c) 60 (d) 50		ľ	(a) 50	$\Box$	(b) 40	
25.	Weight of iodine required to oxidise 500 mL N Na <sub>2</sub> S	$_2O_3$		(c) 20		(d) 100	
	solution, is:		39.	The normality of a 26			nonia
	(a) $6.35  \text{g}$			(density 0.885 g/mL) is a	рргох	timately:	
24	(c) 127 g			(a) 1.5		(b) 4.0	
26.	25 mL N K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> acidified solution will liberate ioo	line		(c) 0.4		(d) 153	
	from KI solution:		40.	The molarity of pure wat			
	(a) $0.3175 g$			(a) 18 <i>M</i>		(b) 50.0 <i>M</i>	
27	(c) 31.75 g			(c) 55.6 M		(d) 100 M	
27.	The indicator used in iodometric titrations is:	,	41.	$5.0 \text{ g of } \text{H}_2\text{O}_2 \text{ is prese}$			
	(a) phonolphthalein				is 34	4. The molarity of the sol	ution
28.	(c) potassium iodide			is:	_	4 . 0 . 15	_
20.	Which of the following acids is added in the titration oxalic acid and potassium permanganate?	1 ()		(a) 1.5 M		(b) 0.15 <i>M</i>	Ļ
	(a) HNO <sub>3</sub>		40	(c) 3.0 <i>M</i>		(d) 50 M	
	(c) CH <sub>3</sub> COOH		42.	2 N solution of sodium cof strength:	агроі	nate is equivalent to a sol	ution

### Objective Questions for IIT ASPIRANTS

1. The value of n in the following equation is :

$$Cr_2O_7^{2-} + 14H^+ + ne^- \longrightarrow 2Cr^{3+} + 7H_2O$$

(a) 2

(b) 3

(c) 4

(d) 6

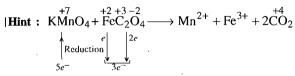

2. The number of moles of acidified  $KMnO_4$  required to oxidise one mole of ferrous oxalate,  $FeC_2O_4$  is :

(a) 5

(b) 3

(c) 0.6

(d) 1.5

5 mole  $FeC_2O_4 \equiv 3$  mole  $KMnO_4$ 

I mole  $FeC_2O_4 = 0.6$  mole  $KMnO_4$ 

- 3. A solution contains Na<sub>2</sub>CO<sub>3</sub> and NaHCO<sub>3</sub>. 10 mL of the solution required 2.5 mL of 0.1 *M* H<sub>2</sub>SO<sub>4</sub> for neutralization using phenolphthalein as indicator. Methyl orange is then added when a further 2.5 mL of 0.2 *M* H<sub>2</sub>SO<sub>4</sub> was required. Then amounts of Na<sub>2</sub>CO<sub>3</sub>-and NaHCO<sub>3</sub> in 1 litre of the solution are:
  - (a) 5.3 g and 4.2 g
- (b) 3.3 g and 6.2 g
- (c) 4.2 g and 5.3 g
- (d) 6.2 g and 3.3 g
- **4.**  $V_1$  mL of NaOH of normality x and  $V_2$  mL of Ba(OH)<sub>2</sub> of normality y are together sufficient to neutralize exactly, 100 mL of 0.1 N HCl. If  $V_1 : V_2 = 1 : 4$  and if x : y = 4 : 1, what fraction of the acid is neutralised by Ba(OH)<sub>2</sub>?
  - (a) 0.5

(b) 0.33

(c) 0.67

- (d) 0.25
- 5. A 0.518 g sample of limestone is dissolved in HCl and then the calcium is precipitated as  $CaC_2O_4$ . After filtering and washing the precipitate, it requires 40 mL of 0.25 N KMnO<sub>4</sub> solution acidified with  $H_2SO_4$  to titrate it as,

$$MnO_4^- + H^+ + C_2O_4^{2-} \longrightarrow CO_2 + Mn^{2+} + H_2O$$

The percentage of CaO in the sample is:

(a) 54%

(b) 27.1%

(c) 42%

(d) 84%

[**Hint :** Number of milliequivalents of CaC<sub>2</sub>O<sub>4</sub>, KMnO<sub>4</sub> and CaO will be same,

$$40 \times 0.25 = \frac{W56}{2} \times 1000$$
  
 $W = 0.28 \text{ g (Mass of CaO)}$   
% CaO =  $\frac{0.28}{0.518} \times 100 = 54\% \text{ J}$ 

**6.** When 40 mL of 0.1 N HCl and 20 mL of 0.1 M H<sub>2</sub>SO<sub>4</sub> are mixed together, the normality of mixture will be:

(a) 
$$\frac{1}{5}N$$

(b) 
$$\frac{2}{15}$$

(c) 
$$\frac{15}{2}$$

(d) 
$$\frac{5}{1}$$
  $\Lambda$ 

Hint:

$$N_1V_1 + N_2V_2 = N_R(V_1 + V_2)$$

$$0.1 \times 40 + 0.2 \times 20 = N_R \tag{60}$$

$$N_R = \frac{8}{60} = \frac{2}{15}$$

7. What is the normality of 0.3 M H<sub>3</sub>PO<sub>4</sub>, when it undergoes the reaction as:

$$H_3PO_4 + 2OH^- \longrightarrow HPO_3^{2-} + 2H_2O$$
?

(a) 0.3 *N* 

(b) 0.15 /V

(c) 0.60 N

(d) 0.90 N

8. In the mixture of (NaHCO<sub>3</sub> + Na<sub>2</sub>CO<sub>3</sub>), volume of HCl required is x mL with phenolphthalein indicator and y mL with methyl orange indicator in same titration. Hence, volume of HCl for complete reaction of Na<sub>2</sub>CO<sub>3</sub> is:

(a) 2x

(b) y

(c) x/2

(d) (y-x)

|Hint: In presence of phenolphthalein, 50% Na<sub>2</sub>CO<sub>3</sub> is neutralised whereas NaHCO<sub>3</sub> remains unaffected. In presence of methyl orange, both Na<sub>2</sub>CO<sub>3</sub> and NaHCO<sub>3</sub> will be 100% neutralised.

Let volume of HCl for complete reaction of  $Na_2CO_3$ =  $V_1$  ml Volume of HCl for complete reaction of  $NaHCO_3$ 

=  $V_2$  mL With phenolphthalein, 50% Na<sub>2</sub>CO<sub>3</sub> will be neutralised

$$\therefore \qquad \frac{V_1}{2} = x \; , \qquad V_1 = 2x \; |$$

- 9. 40 mL of  $0.05 \, M \, \text{Na}_2 \, \text{CO}_3 \cdot \text{Na} \, \text{HCO}_3 \cdot 2 \, \text{H}_2 \, \text{O}$  (sesquicarbonate) is titrated against  $0.05 \, M \, \, \text{HCl}$ .  $x \, \, \text{mL}$  of HCl is used when phenolphthalein is the indicator and  $y \, \, \text{mL}$  HCl is used when methyl orange is the indicator in two separate titrations, hence (y x) is:
  - (a) 80 mL
- (b) 30 mL
- (c) 120 mL
- (d) none of these
- 10. Equivalent mass of  $H_3PO_2$  when it diproportionates into  $PH_3$  and  $H_3PO_3$  is (molecular mass = M):
  - (a) M

(b) M/2

(c) M/4

(d) 3M/4

[Hint:  $H_3^{+1}O_2 \longrightarrow H_3^{+2}O_3$   $E_{mass} = \frac{M}{2}$  (change in oxidation no. = 2)  $H_3^{+1}O_2 \longrightarrow PH_3$   $E_{mass} = \frac{M}{4}$ 

$$H_3PO_2 \longrightarrow PH_3$$
  $E_{ma}$  (change, in oxidation no. = 4)

The equivalent mass of  $H_3PO_2$  in the process of dispro-

portionation = 
$$\frac{M}{2} + \frac{M}{4} = \frac{3M}{4}$$
]

- 11. The reagent commonly used to determine hardness of water titrimetrically is:
  - (a) oxalic acid
- (b) disodium salt of EDTA
- (c) sodium citrate
- (d) sodium thiosulphate
- 12. The equivalent mass of sodium thiosulphate ( $Na_2S_2O_3 \cdot 5H_2O$ ) in the reaction,

$$2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$$
 is:

(a) 248

(b) 124

(c) 596

(d) 62

13. If 100 mL of the acid is neutralised by 100 mL of 4 M NaOH, the purity of conc. HCl (Sp. gravity = 1.2) is:

(a) 12%

(b) 98%

(c) 73%

(d) 43%

14.	2 moles of FeSO <sub>4</sub> are oxidised by x moles of KMnO <sub>4</sub> in acid
	medium into ferric sulphate, 3 moles of ferric oxalate are
	oxidised by y moles of K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> in acid medium. The value
	of $(x/y)$ is:

(a) 6/5

(b) 2/15

(c) 18/5

(d) 3/5

15. What volume of  $0.05 M \text{ Cr}_2\text{O}_7^2$  in acid medium is needed for complete oxidation of 200 mL of  $0.6 M \text{ FeC}_2\text{O}_4$  solution?

(a) 0.6L

(b) 1.2L

(c) 2.4L

(d) 3.6L

16. KMnO<sub>4</sub> reacts with oxalic acid according to the reaction :  $2KMnO_4 + 5C_2O_4^{2-} + 16H^+ \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O$ 

Then, 20 mL of 0.1 M KMnO<sub>4</sub> is equivalent to:

(a)  $30 \text{ mL of } 0.5 \text{ M C}_2\text{H}_2\text{O}_4$  (oxalic acid)

(b)  $50 \text{ mL of } 0.1 \text{ M C}_2\text{H}_2\text{O}_4$  (oxalic acid)

(c)  $20 \text{ mL of } 0.5 M \text{ C}_2\text{H}_2\text{O}_4$  (oxalic acid)

(d) 10 mL of 0.1 MC<sub>2</sub>H<sub>2</sub>O<sub>4</sub> (oxalic acid)

[**Hint**: 
$$\frac{M_1V_1}{n_1}$$
(KMnO<sub>4</sub>) =  $\frac{M_2V_2}{n_2}$ (H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>)  
$$\frac{0.1 \times 20}{2} = \frac{M_2V_2}{5}$$

 $M_2V_2 = 5$  {It is possible in case of (b)}]

17. Potassium permanganate is titrated against ferrous ammonium sulphate in acidic medium, the equivalent mass of potassium permanganate is:

(a)  $\frac{\text{molecular mass}}{2}$ 

(b) molecular mass

(c)  $\frac{\text{molecular mass}}{2}$ 

(d)  $\frac{\text{molecular mass}}{10}$ 

[Hint: The ionic reaction involved in titration is:

$$MnO_4^- + 5Fe^{2+} + 8H^+ \longrightarrow Mn^{2+} + 4H_2O + 5Fe^{3+}$$
  
Since, a molecule of KMnO<sub>4</sub> accepts 5 electrons in acid medium, its equivalent mass will be  $\left(\frac{molecular\ mass}{5}\right)$ .]

**18.** Number of moles of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> that can be reduced by 1 mole of Sn<sup>2+</sup> ion, is:

(a) 1/3

(b) 3/2

(c) 5/6

(d) 6/5

[Hint: The redox reaction is:

$$\text{Cr}_2\text{O}_7^{2-} + 14\text{H}^+ + 3\text{Sn}^{2+} \longrightarrow 2\text{Cr}^{3+} + 7\text{H}_2\text{O} + 3\text{Sn}^{4+}$$

∴ 1 mole of  $Sn^{2+}$  will reduce 1/3 mole of  $K_2Cr_2O_7$ .]

. 19. Potassium permanganate acts as an oxidising agent in acidic, alkaline as well as neutral media. Which among the following statements is incorrect?

- (a) N = M/5 (in acid medium)
- (b) N = M/3 (in alkaline medium)
- (c) N = M/3 (in neutral medium)
- (d) N = M (in alkaline medium)

20. The number of equivalents of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> required for the volumetric estimation of one equivalent of Cu<sup>2+</sup> is:

(a) 1/3

(b) 1

(c) 3/2

(d) 2/3

[Hint: Number of equivalents of reacting species in a chemical reaction are same.]

21. The equivalent mass of MnSO<sub>4</sub> becomes half of its molecular mass when it is converted into:

(a) MnO<sub>4</sub>

(b)  $MnO_2$  or  $Mn_3O_4$ 

(c)  $MnO_4^{2-}$ 

(d)  $Mn_2O_4^{2-}$ 

[Hint: When  $\stackrel{(+2)}{\text{MnSO}_4}$  is converted to  $\stackrel{(+4)}{\text{MnO}_2}$ , the oxidation number changes by 2, thus

Equivalent mass of MnSO<sub>4</sub> =  $\frac{\text{molecular mass}}{2}$ 

22. A solution of 10 mL of  $M/10 \text{ FeSO}_4$  was titrated with KMnO<sub>4</sub> solution in acidic medium, the amount of KMnO<sub>4</sub> used will be:

(a) 10 mL of 0.5 M

(b) 10 mL of 0.1 M

(c) 10 mL of 0.02 M

(d) 5 mL of 0.1 M

[Hint: The involved reaction is:

$$2KMnO4 + 8H2SO4 + 10FeSO4 \longrightarrow 5Fe2(SO4)3 + 2MnSO4 + K2SO4 + 8H2O$$

$$\frac{M_1V_1}{n_1}$$
 (KMnO<sub>4</sub>) =  $\frac{M_2V_2}{n_2}$  (FeSO<sub>4</sub>)

$$\frac{M_1V_1}{2} = \frac{0.1 \times 10}{10}$$

 $M_1V_1 = 0.2$  {Which is possible in (c)}]

23. Among the following reactions, used in titrations select the reaction(s) in which the chlorine is oxidised:

1.  $MnO_2 + 4HCl \longrightarrow MnCl_2 + Cl_2 + 2H_2O$ 

2.  $H_2 + Cl_2 \longrightarrow 2HCl$ 

3.  $CaOCl_2 + H_2SO_4 \longrightarrow CaSO_4 + H_2O + Cl_2$ 

4.  $NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl$ 

(a) Reaction 2, 3, 4

(b) Reaction 1 only

(c) Reaction 1 and 3

(d) Reaction 4 only

(e) Reaction 2 and 4 only

24. Oxalic acid dihydrate, H<sub>2</sub>C<sub>2</sub>O<sub>4</sub>·2H<sub>2</sub>O(s) is often used as a primary reagent to standardise sodium hydroxide solution. Which of these facts are reasons to choose this substance as a primary standard?

I. It is diprotic.

II. It is a stable compound that can be weighed directly in air.

III. It is available in pure form.

(a) III only

(b) I and II only

(c) II and III only

(d) I, II and III

25. A 20 mL sample of a Ba(OH)<sub>2</sub> solution is titrated with 0.245 M HCl. If 27.15 mL of HCl is required, what is the molarity of the Ba(OH)<sub>2</sub> solution?

(a) 0.166 M

(b) 0.180 M

(c) 0.333 M

(d) 0.666 M

**26.** A solution of which substance can best be used as both titrant and its own indicator in an oxidation-reduction titration?

(a) I<sub>2</sub>

(b) NaOCl

(c) K2Cr2O7

(d) KMnO<sub>4</sub>

27. A 0.2 g sample of benzoic acid, C<sub>6</sub>H<sub>5</sub>COOH is titrated with a 0.120 M Ba(OH)<sub>2</sub> solution. What volume of the Ba(OH)<sub>2</sub> solution is required to reach the equivalence point?

#### Substance

#### Molar mass

#### C<sub>6</sub>H<sub>5</sub>COOH

 $122.1 \text{ g mol}^{-1}$ 

- (a) 6.82 mL
- (b) 13.6 mL
- (c) 17.6 mL
- (d) 35.2 mL
- 28. What mass of magnesium hydroxide is required to neutralise 125 mL of 0.136 M HCl solution?

### Substance

#### Molar mass

 $Mg(OH)_2$ 

- $58.33 \text{ g mol}^{-1}$
- (a) 0.248 g
- (b) 0.496 g
- (c) 0.992 g
- (d) 1.98 g

29. In alkaline medium KMnO<sub>4</sub> reacts as follows,

$$2KMnO_4 + 2KOH \longrightarrow 2K_2MnO_4 + H_2O + [O]$$

Hence, its equivalent mass is:

(a) 31.6

(b) 63.2

(c) 126.4

- (d) 158
- 30. When 20 mL of M/10 NaOH are added to 10 mL of M/10 HCl, the resulting solution will:
  - (a) turn blue litmus red
  - (b) turn phenolphthalein solution pink
  - (c) turn methyl orange red
  - (d) will have no effect on either red or blue litmus

# Matrix Matching Questions for IIT Aspirants

1. Match Column-I with Column-II:

#### Column-I (Acid)

#### Column-II

(Information)

- (a) CH3COOH
- (p) Tribasic  $\left(E = \frac{\text{Mol. mass}}{3}\right)$
- (b) H<sub>3</sub>PO<sub>4</sub>
- (q) Dibasic reducing
- (c) H<sub>2</sub>SO<sub>4</sub>
- (r) Dibasic  $\left(E = \frac{\text{Mol. mass}}{2}\right)$
- (d) H<sub>3</sub>PO<sub>3</sub>

(s) Monobasic (E = Mol. mass)

#### 2. Match Column-I with Column-II:

#### Column-I (Reaction)

(Equivalent mass of reactant)

Column-II

- (a)  $NH_3 \longrightarrow NO_3^-$
- Mol. mass
- (b)  $Fe_2S_3 \longrightarrow FeSO_4 + SO_2$
- (c)  $CaCO_3 + 2HCl \longrightarrow$
- Mol. mass
- $CaCl_2 + H_2O + CO_2$ (d)  $CuS \longrightarrow CuSO_4$
- (s) 50

### tuswers

- (a-s)

- 2. (a-r)
- (b-p)
- (c-q, s)

# **Assertion-Reason Type Questions**

The questions given below consist of an Assertion (A) and **Reason** (R). Use the following keys to choose the appropriate answer:

- (a) If both (A) and (R) are correct and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are correct but (R) is not the correct explanation of (A).
- (c) If (A) is correct but (R) is incorrect.
- (d) If (A) is incorrect but (R) is correct.
- 1. (A) Equivalent mass of  $H_3PO_2$  is equal to its molecular mass.
  - (R) H<sub>3</sub>PO<sub>2</sub> is a monobasic acid.
- 2. (A) When Na<sub>2</sub>CO<sub>3</sub> is titrated against HCl in presence of phenolphthalein indicator, it is converted into NaCl.

- (R) Phenolphthalein shows colour change in the pH range of 3.5 to 4.6.
- 3. (A) 1 mole of H<sub>2</sub>SO<sub>4</sub> is neutralised by 2 moles of NaOH. However, 1 equivalent mass of H<sub>2</sub>SO<sub>4</sub> is neutralised by 1 equivalent of NaOH.
  - (R) Equivalent mass of H<sub>2</sub>SO<sub>4</sub> is half of its molecular mass and the equivalent mass of NaOH is equal to its molecular mass.
- 4. (A) Equivalent mass of KMnO<sub>4</sub> is equal to one-fifth of its molecular mass when it acts as an oxidising agent in acidic medium.
  - (R) Oxidation number of Mn in KMnO<sub>4</sub> is +7.

- **5.** (A) In the reaction,  $2S_2O_3^{2-} + I_2 \longrightarrow S_4O_6^{2-} + 2I^-$ ,  $I_2$  is
  - (R) During oxidation, loss of electron or electrons occur.
- (A) 5 M NaOH solution is diluted 10 times, its molarity becomes 50.
- (R) On dilution, molarity of the solution decreases.
- 7. (A) Iodimetric titrations are redox titrations.
  - (R) The iodine solution acts as an oxidising agent.
- 8. (A) H<sub>3</sub>BO<sub>3</sub> is a monobasic acid.
  - (R) H<sub>3</sub>BO<sub>3</sub> has one ionisable hydrogen atom.

## THOUGHT TYPE QUESTIONS

#### **THOUGHT 1**

Pyrolusite, MnO<sub>2</sub>, is the main ore from which manganese is produced. The manganese content of the ore may be determined by reducing the MnO<sub>2</sub> under acidic conditions to Mn<sup>2+</sup> with the oxalate ion,  $C_2O_4^{2-}$ , the oxalate ion being oxidised to carbon dioxide during the reaction. The analytical determination is carried out by adding a known excess volume of oxalate solution to a suspension of the pyrolusite and digesting the mixture on a hot waterbath until all the MnO<sub>2</sub> has been reduced. The excess, unreacted oxalate solution is then titrated with standardized potassium permanganate, KMnO<sub>4</sub> solution after which the manganese content of the ore can be calculated.

A student prepared a standard solution of sodium oxalate by weighing 3.2 g of the dry anhydrous salt, dissolving it in distilled water and making the solution upto 500 mL. 25 mL of the oxalate solution required 24.76 mL of KMnO<sub>4</sub> solution.

- 1. What is the equivalent mass of MnO<sub>2</sub> in the present titration?
  - (a)  $M_{\text{mass}}/1$
- (b)  $M_{\text{mass}}/2$
- (c) M.mass/3
- (d)  $2M._{mass}/3$
- How many moles of  $C_2O_4^{2-}$  ions will be oxidised by 1 mole  $MnO_4^-$ ?
  - (a) 1/2

(b) 3/2

(c) 5/2

- (d) 7/2
- 3. Molarity of the sodium oxalate solution is .......
  - (a) 0.04776
- (b) 0.07446
- (c) 0.06447
- (d) 0.07644
- What is the molarity of KMnO<sub>4</sub> solution?
  - (a) 0.04776
- (b) 0.01929

(c) 0.038

- (d) 0.028
- 5. Role of KMnO<sub>4</sub> in the given titration can be described as:
  - (a) oxidising agent
  - (b) reducing agent
  - (c) indicator
  - (d) oxidising agent and indicator

### THOUGHT 2

For a series of indicators, the following colours and pH range over which colour change takes place are as follows:

Indicator	Colour change over pH range		
U	Yellow to blue	(pH 0.0 to 1.6)	
V	Red to yellow	(pH 2.8 to 4.1)	
	Red to yellow	(pH 4.2 to 5.8)	
X	Yellow to blue	(pH 6 to 7.7)	
$Y_{\cdot}$	Colourless to red	(pH 8.2 to 10)	

#### Choose the correct option:

- Indicator V could be used to find the equivalence point for 0.1 M acetic acid and 0.1 M ammonium hydroxide solution.
  - (a) True

- (b) False
- 2. Indicator Y could be used to distinguish between the solutions of ammonium chloride and sodium acetate.

- (b) False
- Indicator X could be used to distinguish between the solutions of ammonium chloride and sodium acetate.

- (b) False
- Indicator W would be suitable for use in the determination of the concentration of acetic acid in white vineger by base titration.
  - (a) True

- (b) False
- 5. Indicator U could be used to distinguish between 0.1 M and 0.01 M solution of sulphuric acid.
  - (a) True

### THOUGHT 3

Chemists work with standardized solution, a solution whose concentration is known. The requirements to standardize the solution are:

- 1. the volume of the solution
- 2. the number of moles of solute in that volume

A primary standard solution is used in determining the molarity of a solution. To find the molarity of HCl, 0.317 g of Na<sub>2</sub>CO<sub>3</sub>, the primary standard dissolved in water is used in titrating the solution of HCl. 22.9 mL of acid are required to neutralise the sodium carbonate. This is the needed volume (first requirement). The stoichiometric equation is used to know the second requirement.

 $2HCl(aq.) + Na_2CO_3(aq.) \longrightarrow 2NaCl + H_2O + CO_2 \uparrow$ 

- 1. What is the molarity of HCl in the above case?
  - (a) 0.261 M
- (b) 0.522 *M*

(c) 0.1 M

- (d) 1 M
- Equivalent mass of Na<sub>2</sub>CO<sub>3</sub> in the above equation will be :
  - (a) 106

(b) 53

(c) 26.5

(d) 13.25

3. The suitable indicator in the above titration will be:

- (a) phenolphthalein
- (b) methyl orange

(c) litmus

- (d) bromothymol blue
- 4. Solution of Na<sub>2</sub>CO<sub>3</sub> in water will be:
  - (a) acidic

(b) neutral

(c) basic

- (d) it can not be predicted
- 5. What fraction of Na<sub>2</sub>CO<sub>3</sub> will be neutralized by HCl in presence of phenolphthalein indicator?
  - (a) 1/3

(b) 2/3

(c) 1/2

(d) 1/4

#### **THOUGHT 4**

0.5 g bleaching powder was suspended in water and excess KI is added. On acidifying with dil.  $H_2SO_4$ ,  $I_2$  was liberated which required 50 mL of N/10 hypo( $Na_2S_2O_3\cdot 5H_2O$ ) in presence of starch. The reactions involved are :

I. 
$$CaOCl_2 + H_2SO_4 \longrightarrow CaSO_4 + H_2CHCl_2$$

II. 
$$2KI + Cl_2 \longrightarrow 2KCl + I_2$$

- III.  $2Na_2S_2O_3 + I_2 \longrightarrow Na_2S_4O_6 + 2NaI$
- 1. In the reaction (I), which one is reduced?
  - (a) CaOCl<sub>2</sub>
- (b) H<sub>2</sub>SO<sub>4</sub>

(c) Both

- (d) None
- 2. In the given titration, starch acts as:
  - (a) oxidising agent
- (b) indicator
- (c) reducing agent
- (d) catalyst
- 3. In reaction (II), Cl<sub>2</sub> acts as:
  - (a) reducing agent
  - (b) oxidising agent
  - (c) indicator
  - (d) both oxidising agent and indicator
- 4. Percentage of available chlorine in bleaching powder is:
  - (a) 35.5%

- (b) 71%
- (c) 17.25%
- (d) 50%
- 5. Starch forms iodo-starch complex in the given titration. The colour of the complex will be:
  - (a) green

- (b) blue
- (c) pale yellow
- (d) milky white

### Answer

Thought 1	<b>1.</b> (b)	<b>2.</b> (c)	<b>3.</b> (a)	<b>4.</b> (b)	5. (d)

### INTEGER ANSWER Type Questions

The answer to each of the following questions is a single digit integer, ranging from 0 to 9.

- 1. An aqueous solution of 0.63 g oxalic acid dihydrate is made up to 250 mL. The volume of 0.1 N NaOH required to completely neutralise 10 mL of this solution is:
- 2. In the standardisation of  $Na_2S_2O_3$  using  $K_2Cr_2O_7$  by iodometry, the equivalent mass of  $K_2Cr_2O_7$  is M/x. What is the value of x if M is the molecular mass of  $K_2Cr_2O_7$ ?
- 3. A sample of MnO<sub>2</sub> having percentage purity 13.05 is treated with HCl, liberating chlorine which is passed into KI solution.

- 30 mL of 0.1 M Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> are required to titrate the liberated iodine. What was the mass of MnO<sub>2</sub> sample taken?
- **4.** A solution is formed by diluting 250 mL 4 N H<sub>2</sub>SO<sub>4</sub> with 750 mL of water. The normality of the diluted solution is:
- **5.** 100 mL solution consists 8 g of NaOH. The normality of the solution is :
- **6.** If 300 mL of 3 N HCl is mixed with 300 mL of 6 N  $H_2SO_4$ . The final normality of the  $H_2SO_4$  in the resultant solution is:

#### Answers

1. (4) Eq. mass of oxalic acid dihydrate  $=\frac{126}{2}=63$ 

Normality of solution  $= \frac{4 \times 0.63}{63} = 0.04 \text{ N}$  $10 \times 0.04 = V \times 0.1 \qquad i.e., V = 4 \text{ mL}$ 

2. (6)  $K_2Cr_2O_7 + 6KI + 7H_2SO_4 \longrightarrow 4K_2SO_4 + Cr_2(SO_4)_3 + 7H_2O + 3I_2$ 

Change in oxidation state of Cr per molecule = 12 - 6 = 6Thus, Eq. mass of  $K_2Cr_2O_7 = M/6$ i.e., x = 6

3. (1) 30 mL 0.1 M Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>  $\equiv$  30 mL 0.1 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>  $\equiv$  30 mL 0.1 N Cl<sub>2</sub>  $\equiv$  30 mL 0.1 N MnO<sub>2</sub>

Amount of MnO<sub>2</sub> =  $\frac{87}{2} \times \frac{0.1 \times 30}{1000} = 0.1305 \text{ g}$ Mass of sample =  $\frac{100}{13.05} \times 0.1305 = 1$ 

4. (1) Total volume of diluted solution = 1000 mL

Normality 
$$=\frac{250\times4}{1000}=1$$

- 5. (2) Normality  $=\frac{8}{40} \times \frac{1000}{100} = 2$
- 6. (3) Total volume becomes = 600 mL

Normality 
$$=\frac{300\times6}{600}=3 \text{ N}$$

# CHAPTER 18

# Qualitative Inorganic Analysis

#### Contents:

- 18.1 Introduction
- 18.2 Identification of Acidic Radicals
- **18.3** Identification of Acidic Radicals with Sodium Carbonate Extract
- 18.4 Identification of Basic Radicals
- **18.5** Chemical Reactions Involved in the Tests of Basic Radicals
- **18.6** Dry Tests

#### 18.1 INTRODUCTION

Qualitative inorganic analysis deals with the identification of radicals (cations and anions) in an inorganic salt or in a mixture of salts. A salt consists of two parts known as radicals. The positively charged part of a salt (cation) which has been derived from a base is termed **basic radical** and the negatively charged part of the salt (anion) which has been derived from an acid is termed **acidic radical**. For example, the salt copper sulphate is obtained by the action of a base (copper hydroxide) and an acid (sulphuric acid). Thus, it has copper ion ( $Cu^{2+}$ ) as a basic radical and sulphate ion ( $SO_4^{2-}$ ) as the acidic radical.

$$\begin{array}{cccc} Cu(OH)_2 \, + \, H_2SO_4 & \longrightarrow CuSO_4 \, + \, H_2O \\ & & Salt \\ & & & Cu^{2^+} & SO_4^{2^-} \\ & & & & Basic\ radical & Acidic\ radical \end{array}$$

A mixture may have two or more salts; thus qualitative inorganic analysis consists in identifying the presence of various cations and anions in it.

#### 18.2 IDENTIFICATION OF ACIDIC RADICALS

Most of these salts are acted upon by dilute  $H_2SO_4$  or dilute HCl and concentrated  $H_2SO_4$ . In each case, a gas is liberated which is characteristic of the particular acidic radical. There are some acidic radicals which are not decomposed either by dilute  $H_2SO_4$  or concentrated  $H_2SO_4$ . Hence, for the identification of the acidic radicals, the following scheme is followed:

- **Group I:** This group consists of radicals which are detected by dilute  $H_2SO_4$  or dilute HCl. These are (i) carbonate, (ii) sulphite, (iii) sulphide, (iv) nitrite and (v) acetate.
- **Group II:** This group consists of radicals which are detected by concentrated  $H_2SO_4$ . These are (i) chloride, (ii) bromide, (iii) iodide, (iv) nitrate and (v) oxalate.
- **Group III:** The radicals which do not give any characteristic gas with dilute and concentrated  $H_2SO_4$ . These are (i) sulphate, (ii) phosphate, (iii) borate and (iv) fluoride.

#### **GROUP I**

Take 0.2 g of the substance in a test tube and add 2 mL of dilute HCl or dilute  $H_2SO_4$ . Observe the reaction in cold, warm gently the contents and infer as follows:

S.No.	Observation	Inference	Confirmatory tests
1.	Brisk effervescence	CO <sub>3</sub> <sup>2-</sup>	Pass the gas in a test tube
	in cold with evolution	(Carbonate)	containing small quantity
	of colourless and odo-		of lime water. It turns

	with smell of vinegar.	(Acetate)	tion of substance add
		} · ' ·	neutral FeCl <sub>3</sub> solution
			→ blood red colour.
			(b) Rub the moistened
			salt or mixture with
			dry oxalic acid →
			smell of vinegar.

#### Reactions with explanations

(i) Carbonate: The carbonates are decomposed with dilute HCl or dilute  $H_2SO_4$  with the evolution of carbon dioxide gas. When this gas is passed through lime water, the lime water turns milky with the formation of calcium carbonate.

$$Na_2CO_3 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O + CO_2$$
  
 $Ca(OH)_2 + CO_2 \longrightarrow CaCO_3 + H_2O$   
Lime water White ppt.

However, if the CO<sub>2</sub> gas is passed in excess, the milky solution becomes colourless due to the formation of soluble calcium bicarbonate.

$$CaCO_3 + H_2O + CO_2 \longrightarrow Ca(HCO_3)_2$$
.  
White ppt. Soluble

**Note:** (a) Carbonates of bismuth and barium are not easily decomposed by dilute H<sub>2</sub>SO<sub>4</sub>. Dilute HCl should be used.

(b) Sulphur dioxide evolved from sulphites also turns lime water milky. In the test of carbonates, the evolved gas must be colourless and odourless (SO<sub>2</sub> is a pungent gas).

$$\begin{array}{c} \text{Ca(OH)}_2 + \text{SO}_2 & \longrightarrow \text{CaSO}_3 + \text{H}_2\text{O} \\ & \text{White ppt.} \end{array}$$

- (c) PbCO<sub>3</sub> reacts with HCl or H<sub>2</sub>SO<sub>4</sub> to give, in the initial stage, some effervescence but the reaction slows down due to formation of a protective insoluble layer of PbCl<sub>2</sub> or PbSO<sub>4</sub> on the surface of remaining salt or mixture.
- (ii) Sulphite: A sulphite with dilute H<sub>2</sub>SO<sub>4</sub> gives out sulphur dioxide gas which possesses suffocating smell of burning sulphur. When acidified potassium dichromate paper is exposed to the gas it attains green colour due to the formation of chromic sulphate.

$$\begin{array}{c} Na_2SO_3 \,+\, H_2SO_4 \longrightarrow Na_2SO_4 \,+\, H_2O \,+\, SO_2 \\ K_2Cr_2O_7 \,+\, H_2SO_4 \,+\, 3SO_2 \longrightarrow K_2SO_4 \,+\, Cr_2(SO_4)_3 + H_2O \end{array}$$

(iii) Sulphide: Dilute  $H_2SO_4$  decomposes a sulphide salt to form  $H_2S$  gas which smells like rotten eggs.

$$Na_2S + H_2SO_4 \longrightarrow Na_2SO_4 + H_2S$$

On exposure to this gas, the lead acetate paper turns black due to the formation of lead sulphide.

$$Pb(CH_3COO)_2 + H_2S \longrightarrow PbS + 2CH_3COOH$$
  
Black ppt.

Note: Sulphides of lead, cadmium, nickel, cobalt, antimony and stannic are not decomposed with dilute H<sub>2</sub>SO<sub>4</sub>. Conc. HCl should be used for their test. In such cases, however, brisk evolution of H<sub>2</sub>S takes place even by use of dilute H<sub>2</sub>SO<sub>4</sub> if a pinch of zinc dust is added.

$$Zn + H_2SO_4 \longrightarrow ZnSO_4 + 2H$$
  
 $HgS + 2H \longrightarrow Hg + H_2S$ 

(iv) Nitrite: When a nitrite is treated with dilute H<sub>2</sub>SO<sub>4</sub>, it yields a colourless nitric oxide gas which in contact with oxygen of the air becomes brown due to the formation of nitrogen dioxide.

$$\begin{array}{c} 2\text{NaNO}_2 + \text{H}_2\text{SO}_4 & \longrightarrow \text{Na}_2\text{SO}_4 + 2\text{HNO}_2 \\ & \text{Nitrous acid} \\ 3\text{HNO}_2 & \longrightarrow \text{H}_2\text{O} + 2\text{NO} + \text{HNO}_3 \\ 2\text{NO} + \text{O}_2 & \longrightarrow \text{2NO}_2 \\ & \text{Brown coloured gas} \end{array}$$

(a) On passing the gas in dilute FeSO<sub>4</sub> solution, brown coloured complex salt is formed.

$$FeSO_4 \cdot 7H_2O + NO \longrightarrow [Fe(H_2O)_5NO] \cdot SO_4 + 2H_2O$$
Brown coloured

(b) When a mixture of iodide and nitrite is acted upon by dilute H<sub>2</sub>SO<sub>4</sub>, the iodide is decomposed giving violet vapours of iodine.

(c) Starch-iodide paper is turned blue due to the liberation of iodine from iodide by nitrous acid which gives blue colour with starch.

$$2NaNO_2 + H_2SO_4 \longrightarrow Na_2SO_4 + 2HNO_2$$
 
$$2KI + 2CH_3COOH + 2HNO_2 \longrightarrow 2CH_3COOK + 2NO + 2H_2O + I_2$$

 $I_2 + Starch \longrightarrow Blue colour$ 

(v) Acetate: Acetates when heated with dilute H<sub>2</sub>SO<sub>4</sub> decompose to give acetic acid vapours which possess characteristic smell of vinegar.

(a) All acetates are soluble in water. On addition of neutral FeCl<sub>3</sub> solution to the solution of an acetate, blood red colouration develops due to the formation of ferric acetate.

Note: (i) The ferric chloride solution supplied in the laboratory is always acidic containing HCl. It is made neutral by the addition of dilute solution of NH<sub>4</sub>OH drop by drop with

- constant stirring till the precipitate formed does not dissolve. At this stage filter the solution. The filtrate is called neutral ferric chloride solution.
- (ii) Before testing acetate in the aqueous solution of a salt or a mixture, it must be made sure that the solution does not contain the following ions which also combine with Fe<sup>3+</sup> ions.

(i)  $CO_3^{2-}$ , (ii)  $SO_3^{2-}$ , (iii)  $PO_4^{3-}$ , (iv)  $\Gamma$ 

These ions can be removed by addition of AgNO<sub>3</sub> solution and only after the removal of these ions, the test of acetate should be performed by neutral ferric chloride solution.

(b) Acetates are also decomposed with oxalic acid and give off acetic acid.

$$2CH_3COONa + H_2C_2O_4 \longrightarrow Na_2C_2O_4 + 2CH_3COOH$$

#### **GROUP II**

Take 0.2 g of the substance and add 2 mL of concentrated H<sub>2</sub>SO<sub>4</sub>, warm gently, observe the changes and draw inference as follows:

Note: With concentrated H<sub>2</sub>SO<sub>4</sub>, carbonates, sulphites, sulphides, nitrites and acetates also behave in the same way as with dilute H<sub>2</sub>SO<sub>4</sub>.

~ N				
S. No.	Observation	Inference	Confirmatory tests	
1.	Colourless gas with pungent smell which fumes in air. [Add a pinch of $MnO_2$ in the solution $\longrightarrow$ pale green gas is	Cl <sup>-</sup> (Chloride)	(a) Bring a glass rod dipped in NH <sub>4</sub> OH on the mouth of test tube; white fumes are formed.	
	evolved.]		(b) Bring a glass rod dipped in silver nitrate solution on the mouth- of the test tube; white curdy ppt. is formed on the rod.	
			(c) Chromyl chloride test: To the substance in a dry test tube add three times its weight of powdered K <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> and conc. H <sub>2</sub> SO <sub>4</sub> . Heat the contents. Red vapours are evolved. Pass the vapours in a test tube containing NaOH solution. Now add acetic acid and lead acetate solution. A yellow precipitate appears.	
2.	Reddish brown fumes which intensify on addition of MnO <sub>2</sub> . Vapours passed in water, make it yellow.	Br <sup>-</sup> (Bromide)	(a) Take aqueous extract of the substance (or extract with dilute HNO <sub>3</sub> ) and add silver nitrate solution. A light yellow precipitate appears.	
•			(b) To a small amount of the substance add dilute H <sub>2</sub> SO <sub>4</sub> . Warm and cool. Add 1 mL chloroform or carbon tetrachloride and then chlorine water with constant shaking. The chloroform layer becomes orange-brown.	
3.	Violet pungent fumes evolved which may condense as black specks on the cooler parts of the test tube. [The	I <sup>-</sup> (Iodide)	(a) Place a piece of filter paper moistened with starch solution on the mouth of the test tube. The paper turns blue.	
	violet fumes intensify on addition of MnO <sub>2</sub> .]		(b) Take aqueous extract of the substance (or extract with dilute HNO <sub>3</sub> ) and add AgNO <sub>3</sub> solution. Yellow precipitate is formed which is insoluble in NH <sub>4</sub> OH solution.	
*			(c) To the small amount of the substance add dil. H <sub>2</sub> SO <sub>4</sub> and 1 mL of either chloroform or carbon tetrachloride and then chlorine water, shake. Chloroform layer attains violet colouration.	
4.	Light brown vapours having pungent smell. Intensify on adding copper turnings.	NO <sub>3</sub> (Nitrate)	Take an aqueous extract of the substance in a test tube and add freshly prepared FeSO <sub>4</sub> solution. Add conc. H <sub>2</sub> SO <sub>4</sub> by the side of the test tube without disturbing the solution—a brown ring is formed at the junction of two liquids.	
5.	Colourless, odourless gas which burns with blue flame at the mouth of the test tube and turns lime water milky.	$C_2O_4^{2-}$ (Oxalate)	(a) Take the substance, add dil. H <sub>2</sub> SO <sub>4</sub> and heat till there are no more effervescences. Now add MnO <sub>2</sub> (solid)-brisk effervescences.	
			(b) Calcium chloride test, see page 890.	

#### Reactions with explanations

(i) Chloride: Colourless pungent fumes of hydrogen chloride are evolved on heating the solid chloride with conc.  $H_2SO_4$ .

$$NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl$$

(a) Yellowish-green gas of chlorine with suffocating odour is evolved when the solid chloride mixed with manganese dioxide is heated with conc. H<sub>2</sub>SO<sub>4</sub>.

$$NaCl + H_2SO_4 \longrightarrow NaHSO_4 + HCl$$
  
 $MnO_2 + 4HCl \longrightarrow MnCl_2 + 2H_2O + Cl_2$ 

(b) The gas evolved by heating chloride with sulphuric acid forms white fumes of ammonium chloride with NH₄OH.

$$NH_4OH + HCl \longrightarrow NH_4Cl + H_2O$$
White fumes

(c) The gas evolved by heating chloride with H<sub>2</sub>SO<sub>4</sub> forms a curdy precipitate of silver chloride with silver nitrate solution.

$$AgNO_3 + HCl \longrightarrow AgCl + HNO_3$$

**Note:** The curdy precipitate dissolves in ammonium hydroxide by forming a complex salt.

$$AgCl + 2NH_4OH \longrightarrow Ag(NH_3)_2Cl + 2H_2O$$

When the solution having the silver complex is acidified with dilute nitric acid, a white precipitate of silver chloride is again formed.

$$Ag(NH_3)_2Cl + 2HNO_3 \longrightarrow AgCl + 2NH_4NO_3$$

(d) Chromyl chloride test: When solid chloride is heated with conc. H<sub>2</sub>SO<sub>4</sub> in presence of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>, deep red vapours of chromyl chloride are evolved.

$$\begin{array}{c} \text{NaCl} + \text{H}_2\text{SO}_4 \longrightarrow \text{NaHSO}_4 + \text{HCl} \\ \text{K}_2\text{Cr}_2\text{O}_7 + 2\text{H}_2\text{SO}_4 \longrightarrow 2\text{KHSO}_4 + 2\text{CrO}_3 + \text{H}_2\text{O} \\ \text{CrO}_3 + 2\text{HCl} \longrightarrow \text{CrO}_2\text{Cl}_2 + \text{H}_2\text{O} \\ \text{Chromyl chloride} \end{array}$$

When these vapours are passed through NaOH solution, the solution becomes yellow due to the formation of sodium chromate.

$$CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O$$
  
Yellow colour

The yellow solution is neutralised with acetic acid and on addition of lead acetate gives a yellow precipitate of lead chromate.

$$Na_2CrO_4 + Pb(CH_3COO)_2 \longrightarrow PbCrO_4 + 2CH_3COONa$$
  
Yellow ppt.

- Note: (i) This test is not given by the chlorides of mercury, tin, silver, lead and antimony. In such cases this test may be performed by taking the residue obtained after evaporation of sodium carbonate extract.
  - (ii) The chromyl chloride test is always to be performed in a dry test tube; otherwise the chromyl chloride vapours will be hydrolysed in the test tube.

$$CrO_2Cl_2 + 2H_2O \longrightarrow H_2CrO_4 + 2HCl$$

- (iii) The test is said to be positive when all the three observations, viz., orange-yellow (red) vapours of chromyl chloride, yellow solution of sodium chromate, yellow precipitate of lead chromate, are correct.
- (iv) Sometimes, a white precipitate is obtained after the addition of lead acetate solution even in absence of chloride. This may be due to strong heating of the mixture with conc. H<sub>2</sub>SO<sub>4</sub> when H<sub>2</sub>SO<sub>4</sub> vapours are absorbed in NaOH solution or due to incomplete neutralisation of NaOH solution which reacts with lead acetate to form lead hydroxide.
- (v) Bromides and iodides do not give this test.
- (ii) Bromide: Reddish-brown fumes of bromine are formed when the solid bromide is heated with conc.  $H_2SO_4$ .

$$NaBr + H_2SO_4 \longrightarrow NaHSO_4 + HBr$$
  
 $2HBr + H_2SO_4 \longrightarrow Br_2 + 2H_2O + SO_2$ 

More reddish-brown fumes of bromine are evolved when MnO<sub>2</sub> is added.

$$2NaBr + 2H_2SO_4 \longrightarrow 2NaHSO_4 + 2HBr$$

$$MnO_2 + H_2SO_4 \longrightarrow MnSO_4 + H_2O + [O]$$

$$2HBr + [O] \longrightarrow H_2O + Br_2$$

$$2\text{NaBr} + \text{MnO}_2 + 3\text{H}_2\text{SO}_4 \longrightarrow 2\text{NaHSO}_4 + \text{MnSO}_4 + 2\text{H}_2\text{O}_4 + \vec{\text{Bi}}_2$$

(a) The aqueous solution of bromide gives pale yellow precipitate of silver bromide which dissolves in excess of NH<sub>4</sub>OH forming a soluble complex. [AgBr is sparingly soluble in NH<sub>4</sub>OH solution.]

$$NaBr + AgNO_3 \longrightarrow AgBr$$
 +  $NaNO_3$  Pale yeliow ppt.

$$AgBr + 2NH_4OH \longrightarrow Ag(NH_3)_2Br + 2H_2O$$

(b) When the fresh salt or mixture is treated with dilute H<sub>2</sub>SO<sub>4</sub>, CHCl<sub>3</sub> or CCl<sub>4</sub> and chlorine water, chlorine replaces bromine and the liberated bromine dissolves in CHCl<sub>3</sub> or CCl<sub>4</sub> layer giving it brown colour.

$$2KBr + Cl_2 \longrightarrow 2KCl + Br_2$$

**Note:** Excess of chlorine water should not be used. Under this condition the layer attains either pale yellow colour due to formation of bromine monochloride or it becomes colourless due to formation of hypobromous acid.

$$\begin{array}{ccc} Br_2 + Cl_2 & \longrightarrow & 2Br \cdot Cl \\ & \text{Bromine monochloride} \\ Br_2 + 2H_2O + Cl_2 & \longrightarrow & 2HBrO \\ & \text{Hypobromous acid} \end{array} + 2HCl_2$$

(iii) **Iodide:** Violet vapours of iodine are evolved on heating iodide with concentrated  $H_2SO_4$ .

$$2KI + 2H_2SO_4 \longrightarrow 2KHSO_4 + 2HI$$
  
 $2HI + H_2SO_4 \longrightarrow I_2 + SO_2 + 2H_2O_3$ 

More violet vapours are evolved when MnO2 is added.

$$2KI + 2H2SO4 \longrightarrow 2KHSO4 + 2HI$$

$$MnO2 + H2SO4 \longrightarrow MnSO4 + H2O + [O]$$

$$2HI + [O] \longrightarrow H2O + I2$$

$$2KI + MnO_2 + 3H_2SO_4 \longrightarrow 2KHSO_4 + MnSO_4 + 2H_2O + I_2$$

(a) Violet vapours with starch produce blue colour.

$$I_2$$
 + Starch  $\longrightarrow$  Blue colour

(b) Aqueous solution of the iodine gives yellow precipitate of AgI with silver nitrate solution which does not dissolve in NH<sub>4</sub>OH.

$$NaI + AgNO_3 \longrightarrow AgI + NaNO_3$$
  
Yellow ppt.

(c) When the given substance is treated with dilute H<sub>2</sub>SO<sub>4</sub>, CHCl<sub>3</sub> or CCl<sub>4</sub> and chlorine water, chlorine replaces iodine which dissolves in CHCl<sub>3</sub> or CCl<sub>4</sub> layer giving it violet colour.

$$2KI + Cl_2 \longrightarrow 2KCI + I_2$$
  
 $I_2 + CHCl_3 \longrightarrow Violet layer$ 

**Note:** Excess of chlorine water should be avoided as the layer becomes colourless with the conversion of iodine into iodic acid.

$$[Cl2 + H2O \longrightarrow 2HCl + O] \times 5$$

$$I2 + H2O + 5[O] \longrightarrow 2HIO3$$

$$I2 + 5Cl2 + 6H2O \longrightarrow 2HIO3 + 10HCl$$

(iv) Nitrate: Light brown fumes of nitrogen dioxide are evolved on heating the nitrate with concentrated H<sub>2</sub>SO<sub>4</sub>.

$$NaNO_3 + H_2SO_4 \longrightarrow NaHSO_4 + HNO_3$$
  
 $4HNO_3 \longrightarrow 2H_2O + 4NO_2 + O_2$ 

These fumes intensify when copper turnings are added.

$$Cu + 4HNO_3 \longrightarrow Cu(NO_3)_2 + 2NO_2 + 2H_2O$$

Ring Test: When the aqueous solution of the substance is treated with freshly prepared solution of ferrous sulphate and conc. H<sub>2</sub>SO<sub>4</sub>, a brown ring is formed on account of the formation of a complex at the junction of two liquids.

$$\begin{array}{c} NaNO_3 \,+\, H_2SO_4 \longrightarrow \, NaHSO_4 \,+\, HNO_3 \\ 6FeSO_4 \,+\, 2HNO_3 \,+\, 3H_2SO_4 \longrightarrow \, 3Fe_2(SO_4)_3 + 4H_2O + 2NO \\ [Fe(H_2O)_6]SO_4 \cdot H_2O \,+\, NO \,\longrightarrow \, [Fe(H_2O)_5NO]SO_4 + 2H_2O \\ \text{Ferrous sulphate} \end{array}$$

Note: (a) Ring test is not reliable in presence of nitrite, bromide and iodide.

(b) The nitrates can be tested by boiling nitrate with Zn or Al in presence of concentrated NaOH solution when ammonia is evolved which can be detected by the characteristic odour.

$$Zn + 2NaOH \longrightarrow Na_2ZnO_2 + 2H$$
  
 $Al + NaOH + H_2O \longrightarrow NaAlO_2 + 3H$   
 $NaNO_3 + 8H \longrightarrow NaOH + 2H_2O + NH_3$ 

(v) Oxalate: When oxalate is heated with conc. H<sub>2</sub>SO<sub>4</sub>, a mixture of CO and CO<sub>2</sub> is given off. The CO burns with blue flame.

$$Na_2C_2O_4 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2C_2O_4$$
  
 $H_2C_2O_4 + [H_2SO_4] \longrightarrow CO + CO_2 + H_2O + [H_2SO_4]$ 

#### **GROUP III**

Some anions are identified by their characteristic chemical reactions. These radicals are sulphate, borate, phosphate and fluoride.

(i) Sulphate: Dissolve a little amount of the substance (salt or mixture) and add barium chloride solution. A white precipitate insoluble in conc. HNO<sub>3</sub> is formed.

#### Reactions with explanations

White precipitate of barium sulphate is obtained when soluble sulphate is treated with barium chloride solution.

$$Na_2SO_4 + BaCl_2 \longrightarrow 2NaCl + BaSO_4$$
  
White ppt

The white precipitate is insoluble in conc. HNO<sub>3</sub>. Certain chlorides, e.g., NaCl and BaCl<sub>2</sub> when present in large quantities, may form a white precipitate which dissolves on dilution with water.

Silver and lead, if present, may be precipitated as silver chloride and lead chloride by the addition of barium chloride. To avoid it, barium nitrate may be used in place of barium chloride.

(ii) Borate: To a small quantity of the substance (salt or mixture), add a few mL of ethyl alcohol and conc. H<sub>2</sub>SO<sub>4</sub>. Stir the contents with a glass rod. Heat the test tube and bring the mouth of the test tube near the flame. The formation of green edged flame indicates the presence of borate.

#### Reactions with explanations

When borate is heated with ethyl alcohol and H<sub>2</sub>SO<sub>4</sub>, ethyl borate vapours come out which burn with green edged flame.

$$2Na_3BO_3 + 3H_2SO_4 \longrightarrow 3Na_2SO_4 + 2H_3BO_3$$

$$H_3BO_3 + 3C_2H_5OH \longrightarrow (C_2H_5)_3BO_3 + 3H_2O$$
Ethyl borate

In place of ethyl alcohol, methyl alcohol can also be used. This test should be performed in a test tube and not in a porcelain basin because copper or barium salts, if present, will come in contact with the flame which also give green flame.

(iii) Phosphate: Take about 0.2 g of the substance in a test tube and add 2 mL conc. HNO<sub>3</sub>. Heat and add 2 mL ammonium molybdate solution. Again heat. A canary yellow precipitate indicates the presence of phosphate.

#### Reactions with explanations

The canary yellow precipitate is due to the formation of ammonium phosphomolybdate.

$$Ca_{3}(PO_{4})_{2} + 6HNO_{3} \longrightarrow 3Ca(NO_{3})_{2} + 2H_{3}PO_{4}$$

$$H_{3}PO_{4} + 12(NH_{4})_{2}MoO_{4} + 21HNO_{3} \longrightarrow (NH_{4})_{3} \cdot PO_{4} \cdot 12MoO_{3}$$

$$(Canary yellow ppt.)$$

$$+ 21NH_{4}NO_{3} + 12H_{2}O$$

Arsenic under similar conditions also yields a yellow precipitate of (NH<sub>4</sub>)<sub>3</sub>·AsO<sub>4</sub>·12MoO<sub>3</sub> (ammonium arsenomolybdate). So, in presence of As, phosphate is tested in the filtrate of second group.

(a) The precipitate of ammonium phosphomolybdate dissolves in excess of phosphate. Thus, the reagent (ammonium molybdate) should always be added in excess.

- (b) HCl interferes in this test. Hence, if the test of phosphate is to be performed with the solution containing HCl, the solution should be boiled to remove HCl.
- (c) Reducing agents such as sulphites, sulphides, etc., interfere as they reduce Mo(VI) to molybdenum blue  $(Mo_3O_8.xH_2O)$ . The solution, therefore, turns blue. In the presence of reducing agents, the solutions should be boiled with  $HNO_3$  as to oxidise them before the addition of ammonium molybdate.
- (iv) Fluoride: Take a small amount of the substance in a dry test tube and add an equal amount of sand. Mix the contents and add conc. H<sub>2</sub>SO<sub>4</sub>. Heat the contents and place a glass rod moistened with water over the mouth of the test tube. A waxy white deposit on the rod is formed.

#### Reactions with explanations

The fluoride with conc. H<sub>2</sub>SO<sub>4</sub> forms H<sub>2</sub>F<sub>2</sub> (hydrofluoric acid) which attacks silica forming silicon tetrafluoride, SiF<sub>4</sub>. The vapours of SiF<sub>4</sub> are hydrolysed by H<sub>2</sub>O into gelatinous silicic acid which is deposited on the rod.

$$\begin{array}{c} 2\text{NaF} + \text{H}_2\text{SO}_4 & \longrightarrow \text{Na}_2\text{SO}_4 + \text{H}_2\text{F}_2 \\ \text{SiO}_2 + 2\text{H}_2\text{F}_2 & \longrightarrow \text{SiF}_4 + 2\text{H}_2\text{O} \\ 3\text{SiF}_4 + 4\text{H}_2\text{O} & \longrightarrow \text{H}_4\text{SiO}_4 + 2\text{H}_2\text{SiF}_6 \\ & \text{Silicic acid} \\ \text{(White)} \end{array}$$

- (a) The test should be performed in perfectly dry test tube, otherwise waxy white deposit will not be formed on the rod.
- (b) HgCl<sub>2</sub> and NH<sub>4</sub>Cl also produce a deposit under these conditions, but this deposit is crystalline in nature.

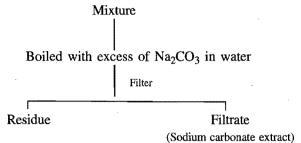

### 18.3 IDENTIFICATION OF ACIDIC RADICALS WITH SODIUM CARBONATE EXTRACT

A large number of acidic radicals can be confirmed by using sodium carbonate extract of the mixture. One part of the given substance is mixed with about 3 parts of sodium carbonate and nearly 10 to 15 mL of distilled water. The contents are then heated for 10–15 minutes and filtered. The filtrate is known as sodium carbonate extract or soda extract.

During the heating of mixture with sodium carbonate, double decomposition takes place, *i.e.*, exchange of partners takes place.

For example,

Thus, carbonates of the cations of the mixture are formed which are mostly insoluble in water and are obtained in the residue. On the other hand, sodium salts of the anions (acidic radicals) of the mixture are formed which being soluble in water are obtained in the filtrate.

Sodium carbonate extract (filtrate) contains:

- (i) Sodium salts of acidic radicals present in the mixture.
- (ii) Unused sodium carbonate and
- (iii) Some soluble compounds like (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub>,K<sub>2</sub>CO<sub>3</sub>, NaAlO<sub>2</sub>, etc.

The sodium carbonate extract is basic in nature and before it is used for the detection and identification of a particular acidic radical, it is first neutralised by the addition of small quantity of an appropriate acid. The acid is added to the extract till the effervescences cease to evolve.

Neutralisation is done according to the following scheme:

Radicals to be tested	Acid used for neutralization	Reagents for testing
Chloride	Dilute HNO <sub>3</sub>	AgNO <sub>3</sub>
Bromide	Dilute HNO <sub>3</sub>	AgNO <sub>3</sub>
Iodide.	Dilute HNO <sub>3</sub>	AgNO <sub>3</sub>
Sulphate	Dilute HCl	· BaCl <sub>2</sub>
Oxalate	Acetic acid	CaCl <sub>2</sub>
Sulphite	Dilute HCl	BaCl <sub>2</sub>

#### Advantages of preparing sodium carbonate extract:

- (i) Many salts are insoluble in water and dilute acids. The preparation of sodium carbonate extract affords a convenient method for bringing the anions of the mixture in solution.
- (ii) It removes the basic radicals (usually coloured) which could have interfered in the usual tests of some of the acidic radicals.
- (iii) The residue can be used for the tests of basic radicals of I to VI groups as it can be easily dissolved in dil. HCl or conc. HCl. Such a solution does not involve the problem of removing interfering radicals like oxalate, fluoride, borate and phosphate.

### Tests of various acidic radicals with sodium carbonate extract:

(i) Sulphide: (a) Take sodium carbonate extract and add few drops of NaOH and then freshly prepared sodium nitroprusside solution. Appearance of violet colour indicates the presence of sulphide.

$$Na_2S + Na_2[Fe(CN)_5NO] \longrightarrow Na_4[Fe(CN)_5NOS]$$
  
Sodium nitroprusside (Violet colour)

(b) To soda extract, add lead acetate solution. A black precipitate indicates the presence of sulphide.

$$Na_2S + Pb(CH_3COO)_2 \longrightarrow PbS + 2CH_3COONa$$

$$\underset{(Black)}{\longleftarrow} + 2CH_3COONa$$

(c) To soda extract add cadmium carbonate. A yellow precipitate indicates the presence of sulphide.

$$Na_2S + CdCO_3 \longrightarrow CdS + Na_2CO_3$$

$$Cadmium sulphide (Yellow)$$

(ii) Sulphite: Acidify the soda extract with dilute HCl and add barium chloride solution followed by bromine water and heat the contents. Appearance of white precipitate indicates the presence of sulphite.

$$\begin{array}{c} \text{Na}_2\text{SO}_3 + \text{BaCl}_2 \longrightarrow \text{BaSO}_3 + 2\text{NaCl} \\ \hline \text{Br}_2 + \text{H}_2\text{O} \longrightarrow 2\text{HBr} + \text{O} \\ \hline \text{BaSO}_3 + \text{O} \longrightarrow \text{BaSO}_4 \\ \text{White ppt.} \end{array}$$

(iii) Sulphate: Acidify the soda extract with dilute HCl or dilute HNO<sub>3</sub> and add barium chloride solution. A white precipitate insoluble in concentrated HCl and concentrated HNO<sub>3</sub> indicates the presence of sulphate.

$$Na_2SO_4 + BaCl_2 \longrightarrow BaSO_4 + 2NaCl$$
White ppt.

(iv) Nitrite: Acidify soda extract with acetic acid and add concentrated solution of cobalt chloride. Then add potassium chloride. Warm the contents and wait for sometime. Appearance of yellow precipitate indicates the presence of nitrite.

$$\begin{array}{c} CoCl_2 + 2NaNO_2 \longrightarrow Co(NO_2)_2 + 2NaCl \\ NaNO_2 + CH_3COOH \longrightarrow CH_3COONa + HNO_2 \\ 2HNO_2 \longrightarrow H_2O + 2NO + [O] \\ 2Co(NO_2)_2 + 2NaNO_2 + H_2O + [O] \rightarrow 2Co(NO_2)_3 + 2NaOH \\ Co(NO_2)_3 + 3NaNO_2 \longrightarrow Na_3[Co(NO_2)_6] \\ Colourless and soluble \\ Na_3[Co(NO_2)_6] + 3KCl \longrightarrow K_3[Co(NO_2)_6] + 3NaCl \\ Potassium cobaltinitrite \\ (Yellow and insoluble) \end{array}$$

(v) Chloride: Acidify sodium carbonate extract with dilute nitric acid and add silver nitrate solution. A white precipitate of silver chloride is formed which dissolves in ammonium hydroxide.

$$NaCl + AgNO_{3} \longrightarrow \underset{White \ ppt.}{AgCl} + NaNO_{3}$$

(vi) **Bromide:** (a) Acidify the sodium carbonate extract with dilute HNO<sub>3</sub> and add silver nitrate solution. A light yellow precipitate of silver bromide is formed which is sparingly soluble in ammonium hydroxide.

NaBr + AgNO<sub>3</sub> 
$$\longrightarrow$$
 AgBr + NaNO<sub>3</sub>  
Silver bromide  
(Pale yellow ppt.)

(b) Take the second part of the sodium carbonate extract and add  $CHCl_3$  or  $CCl_4$  and then chlorine water. Shake the contents. The chloroform layer turns brown.

$$2NaBr + Cl_2 \longrightarrow 2NaCl + Br_2$$
  
 $Br_2 + Chloroform \longrightarrow Brown layer$ 

Note: In place of chlorine water, conc. HNO3 can be used.

(vii) Iodide: (a) Acidify sodium carbonate extract with dilute HNO<sub>3</sub> and add silver nitrate solution. A yellow precipitate of silver iodide appears which does not dissolve in ammonium hydroxide.

$$AgNO_3 + NaI \longrightarrow AgI + NaNO_3$$
  
Yellow ppt.

(b) Take the second part of the soda extract and add chloroform or carbon tetrachloride and then chlorine water. Shake vigorously. The chloroform layer turns violet.

Note: In place of chlorine water, conc. HNO3 can be used.

(viii) Oxalate: Acidify the sodium carbonate extract with acetic acid and add CaCl<sub>2</sub> solution. A white precipitate is obtained. Filter and dissolve the precipitate in dilute H<sub>2</sub>SO<sub>4</sub> and add fewdrops of potassium permanganate solution. The colour of KMnO<sub>4</sub> is discharged. This indicates the presence of oxalate.

$$\begin{array}{c} Na_2C_2O_4 + CaCl_2 \longrightarrow CaC_2O_4 + 2NaCl \\ & \text{White ppt.} \\ CaC_2O_4 + H_2SO_4 \longrightarrow H_2C_2O_4 + CaSO_4 \\ & \text{Calcium oxalate} \\ \hline 2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O] \\ & COOH \\ & | & + [O] \longrightarrow 2CO_2 + H_2O \\ & COOH \\ \end{array}$$

Note: In presence of fluoride, a white precipitate of CaF<sub>2</sub> is also formed by the addition of CaCl<sub>2</sub> solution. But CaF<sub>2</sub> does not dissolve in dil. H<sub>2</sub>SO<sub>4</sub> and does not discharge the colour of KMnO<sub>4</sub>.

#### 18.4. IDENTIFICATION OF BASIC RADICALS

Wet test analysis for basic radicals includes the following steps:

- (a) Preparation of the original solution of the salt or mixture.
  - (b) Separation of basic radicals into different groups.
- (c) Analysis of the precipitates obtained in different groups and confirmation of the basic radicals by specific tests.

#### (a) Preparation of the original solution

The following solvents should be tried strictly in the order given below:

- (i) Cold water,
- (ii) Hot water,
- (iii) Dilute HCl,
- (iv) Concentrated HCl.

- (i) Take about 0.1 g of salt or mixture in a test tube and shake it with 3.4 mL cold distilled water.
- (ii) If the substance is insoluble, heat to boil the contents and shake.
- (iii) If the substance does not dissolve, take fresh quantity about 0.1 g of salt or mixture in a test tube and add about 3 mL dilute HCl and shake. If the substance is insoluble, boil the contents.
- (iv) If the substance is still insoluble, treat fresh amount of 0.1 g of salt or mixture with 2 mL of conc. HCl. Heat to boiling, dilute with 5 mL distilled water and again heat. This treatment will dissolve most of the substances.

After selecting a suitable solvent for the given salt or mixture, take about 10 mL of the solvent in a boiling test tube, heat to boiling, add the solid substance little by little. Continue heating and adding the mixture till a concentrated solution is obtained. Dilute the solution with equal amount of water.

If the solution is to be prepared in concentrated HCl, take about 1.0 g of solid substance in a basin, add 5 mL of concentrated HCl. Evaporate to dryness. Add 1 mL of concentrated HCl to solid residue and 20 mL of distilled water. The solution thus obtained is called the original solution.

**Note:** (i) When the salt or mixture is soluble in cold dilute HCl, it shows that basic radicals Pb<sup>2+</sup>, Hg<sub>2</sub><sup>2+</sup> and Ag<sup>+</sup> are absent.

- (ii) Lead chloride, PbCl<sub>2</sub>, is soluble in hot solution but insoluble in cold solution. Thus, when the hot solution is cooled, if a white substance appears, it shows the presence of Pb<sup>2+</sup>.
- (iii) Sometimes, a white precipitate or milkiness is formed when the solution prepared in concentrated HCl is diluted, even when no member of first group is present. This may be due to formation of the oxychlorides of antimony, bismuth and tin.
   BiCl<sub>3</sub> + H<sub>2</sub>O → BiOCl + 2HCl White ppt.

The precipitate disappears if little concentrated HCl is added. In such a case, H<sub>2</sub>S can be passed through milky solution.

$$2BiOCl + 3H_2S \longrightarrow Bi_2S_3 + 2HCl + 2H_2O$$

- (iv) A white crystalline precipitate of NaCl and BaCl<sub>2</sub> may be formed from the concentrated solution by the addition of concentrated HCl due to common ion effect. Such precipitates dissolve on dilution.
- (v) The original solution should not be prepared in concentrated nitric acid and concentrated H<sub>2</sub>SO<sub>4</sub>. These act as oxidising agents and convert H<sub>2</sub>S into S-in second group. Nitric acid converts sulphides of Ba, Sr, and Pb into insoluble sulphates. Similarly sulphuric acid converts the salts of Ba, Sr and Pb into insoluble sulphates.

### (b) Separation of basic radicals into different groups

For systematic analysis, the basic radicals have been classified into groups. Each group has a reagent, which shows the presence of the basic radical belonging to that particular group. It is necessary that the radical is completely removed in the respective group by using excess of group reagent, otherwise its presence creates difficulty in higher group.

Group	Group reagent	Basic radical	Composition and colour of the precipitate	
1.	Dilute HCl	$Ag^{+}$	AgCl: white	Chlorides
		Pb <sup>2+</sup>	PbCl <sub>2</sub> : white	insoluble in
		Hg <sub>2</sub> <sup>2+</sup>	Hg <sub>2</sub> Cl <sub>2</sub> : white	cold dilute HCl
2.	H <sub>2</sub> S in	Hg <sup>2+</sup>	HgS: black	,
•	presence of	Pb <sup>2+</sup>	PbS: black	*
	dilute HCl	Bi <sup>3+</sup>	Bi <sub>2</sub> S <sub>3</sub> : black	
		Cu <sup>2+</sup>	CuS: black	Sulphides
		$Cd^{2+}$	CdS: yellow	insoluble in
•		As <sup>3+</sup>	As <sub>2</sub> S <sub>3</sub> : yellow	dilute HCl
·····		Sb <sup>3+.</sup>	Sb <sub>2</sub> S <sub>3</sub> :-orange	
	, ,	Sn <sup>2+</sup>	SnS: brown	
		Sn <sup>4+</sup>	SnS <sub>2</sub> : yellow	
3.	NH <sub>4</sub> OH in	Fe <sup>3+</sup>	Fe(OH) <sub>3</sub> :	<u>.</u> ]
	presence of		reddish brown	Hydroxides
	NH <sub>4</sub> Cl	Cr <sup>3+</sup>	Cr(OH) <sub>3</sub> : green	are insoluble — in NH <sub>4</sub> OH
٠.		Al <sup>3+</sup>	Al(OH) <sub>3</sub> : white	
4.	H <sub>2</sub> S in presence of	Zn <sup>2+</sup>	ZnS: greenish white	
	NH <sub>4</sub> OH	Mn <sup>2+</sup>	MnS: buff	Sulphides are insoluble in
*		Co <sup>2+</sup>	CoS: black	NH <sub>4</sub> OH
		Ni <sup>2+</sup>	NiS: black	
5.	(NH <sub>4</sub> ) <sub>2</sub> CO <sub>3</sub> in	Ba <sup>2+</sup>	BaCO <sub>3</sub> : white	]
	presence of	Sr <sup>2+</sup>	SrCO <sub>3</sub> : white	Carbonates are insoluble
	NH <sub>4</sub> OH	Ca <sup>2+</sup>	CaCO <sub>3</sub> : white	are moorable
6.	Na <sub>2</sub> HPO <sub>4</sub>	Mg <sup>2+</sup>	Mg(NH <sub>4</sub> )PO <sub>4</sub> : white	
7.	NaOH	NH <sub>4</sub>	Ammonia gas is evolved.	

### (c) Detection of basic radicals GROUP I

**Radicals:**  $Pb^{2+}$ ,  $Ag^+$ ,  $Hg_2^{2+}$  (ous)

Group reagent: Dil. HCl

**Procedure:** Take cold dilute original solution and add few drops of dilute HCl. If white precipitate appears, add more of dilute HCl as to complete precipitation of basic radicals of first group. Filter, keep the filtrate for subsequent groups.

Wash the precipitate with cold water. Transfer precipitate in a test tube and add about 10 mL of water, boil. If the precipitate dissolves, Pb<sup>2+</sup> is present and if it does not dissolve, it may have Ag<sup>+</sup> or Hg<sub>2</sub><sup>2+</sup>. If the precipitate does not dissolve, filter it.

When the preci- pitate dissolves in hot water	Solid residue (insoluble in hot water), add hot NH <sub>4</sub> OH		
Divide the filtrate in four parts.  (i) First part—cool under tap water—white crystalline ppt. of PbCl <sub>2</sub> .  (ii) Second part +K <sub>2</sub> CrO <sub>4</sub> soln. —yellow ppt. of PbCrO <sub>4</sub> (iii) Third part + KI solution —yellow ppt. of PbI <sub>2</sub>	most of the acids, dilute with water and divide into two parts: Part I: Add stannous chloride solution. A white precipitate appears which turns grey. Part II: Add copper turnings. A grey deposit is formed on	dissolves. Divide the solution into two parts: First part + dil. HNO <sub>3</sub>	
acetate.  Pb <sup>2+</sup> confirmed	Hg <sub>2</sub> <sup>2+</sup> (ous) confirmed		

#### **GROUP II**

**Radicals :**  $Hg^{2+}$ ,  $Pb^{2+}$ ,  $Bi^{3+}$ ,  $Cu^{2+}$ ,  $Cd^{2+}$  Group IIA  $As^{3+}$ ,  $Sb^{3+}$ ,  $Sn^{2+}$ ,  $Sn^{4+}$  Group IIB

Group reagent: H<sub>2</sub>S gas in presence of dil. HCl

**Procedure:** Warm a part of the filtrate of first group or original solution containing dilute HCl (if first group is absent) and pass H<sub>2</sub>S gas. If a precipitate (black or brown or yellow or orange) appears, pass H<sub>2</sub>S through whole of the solution. Filter, dilute the filtrate, warm and again pass H<sub>2</sub>S. Filter. Repeat this process till the precipitation is complete. Keep the filtrate for subsequent groups.

Wash the precipitate with hot water. Take small part of the precipitate in a test tube and add about 5 mL of yellow ammonium sulphide solution, warm upto 60°C with shaking.

If the precipitate does not dissolve, Group IIA radical may be present.

If the precipitate dissolves, Group IIB radical may be present.

Insoluble in yellow ammonium sulphide	Soluble in yellow ammonium sulphide
IIA Group HgS Black PbS Black Bi <sub>2</sub> S <sub>3</sub> Black CuS Black CdS Yellow	IIB Group As <sub>2</sub> S <sub>3</sub> Yellow Sb <sub>2</sub> S <sub>3</sub> Orange SnS Brown SnS <sub>2</sub> Yellow

Note: (i) Before passing H<sub>2</sub>S, the acidic concentration of the solution should be properly adjusted. If the solution is too acidic, lead and cadmium will not be precipitated. On the other hand if too little HCl is used, zinc will also be precipitated. The proper hydrogen ion concentration is 0.25 N to 0.5 N with respect to HCl.

- (ii) The original solution must be free from any oxidising agent otherwise H<sub>2</sub>S gets oxidised with precipitation of free sulphur. This is done by heating the mixture with concentrated HCl for sufficient time during preparation of original solution. This treatment will also remove sulphite, nitrite from the mixture which can oxidise H<sub>2</sub>S.
- (iii) Hydrogen sulphide should be passed slowly in hot solution to get granular and easily filterable precipitate.

#### **GROUP IIA**

**Procedure:** Take the precipitate (if insoluble in yellow ammonium sulphide) in a test tube add 5 mL of dilute HNO<sub>3</sub>. Boil for few minutes. If insoluble, filter it.

Insoluble (black) HgS. Dissolve it in aqua-regia and divide into two parts:  Part I: Add SnCl <sub>2</sub> solution — a white ppt. which changes into greyish coloured ppt.  Part II: Add Cuturnings — a greyish deposit on copper	Soluble—It may have Pb <sup>2+</sup> , Cu <sup>2+</sup> , Bi <sup>3+</sup> or Cd <sup>2+</sup> Divide the solution into two parts:  First part: Add dilute H <sub>2</sub> SO <sub>4</sub> and alcohol.  The appearance of white precipitate confirms the presence of lead. In case no precipitate, use second part of filtrate.  Second part of filtrate + excess of NH <sub>4</sub> OH soln.  White precipitate (then filter) or blue-coloured solution or colourless solution.		
deposit on copper turnings.	White	Blue coloured	Colourless
Hg <sup>2+</sup> (ic) confirmed	precipitate	solution	solution
	Dissolve the ppt. in dilute HCl and divide into three parts: Part I: Add sodium stannite solution — black ppt. Part II: Dilute with water — white ppt. Part III: Add a little 10% thiourea soln. — Yellow colouration.	Acidify the solution with acetic acid and add K4[Fe(CN)6] soln. ————————————————————————————————————	through soln.  Appe-

Note: (i) Sodium stannite is prepared by taking 1 mL of stannous chloride and adding to it drop by drop NaOH till the precipitate formed dissolves.

Bi<sup>3+</sup>present

$$SnCl_2 + 2NaOH \longrightarrow Sn(OH)_2 + 2NaCl$$
 $ppt.$ 
 $Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$ 
 $Sodium stannite$ 
 $(soluble)$ 

(ii) Yellow ammonium sulphide is used only for one radical, i.e., Sn<sup>2+</sup> which is not soluble in ordinary ammonium sulphide. Yellow ammonium sulphide consists excess of sulphur and is formulated as (NH<sub>4</sub>)<sub>2</sub>S<sub>x</sub>, commonly as (NH<sub>4</sub>)<sub>2</sub>S<sub>2</sub>. This converts SnS first into SnS<sub>2</sub> which then dissolves forming thio complex. In case Sn<sup>2+</sup> is absent, ordinary ammonium sulphide can be used in place of yellow ammonium sulphide.

#### **GROUP IIB**

**Procedure:** Take the remaining precipitate (if the precipitate is soluble in yellow ammonium sulphide) and add 1 mL of concentrated HCl and boil. If the precipitate is insoluble, filter and test for arsenic and in case dissolves, test for antimony and tin.

Insoluble in conc. HCl	Soluble in conc. HCl		
Dissolve the yellow ppt. in conc. HNO <sub>3</sub> .	Dilute the solution with water. Divide the solution in two parts.		
Add ammonium molybdate and again heat $\longrightarrow$ yellow ppt. As <sup>3+</sup> confirmed	First part: Add NH <sub>4</sub> OH and pass H <sub>2</sub> S $\longrightarrow$ orange ppt. Sb <sup>3+</sup> confirmed	Second part: Add iron fillings and heat for 10 minutes. Filter into a solution of	
		mercuric chloride  → A white ppt. turning grey, Sn <sup>2+</sup> confirmed	

#### **GROUP III**

**Radicals:**  $Fe^{3+}$ ,  $Al^{3+}$ ,  $Cr^{3+}$ 

 $\textbf{Group reagent:} \quad NH_4OH \, + \, NH_4Cl$ 

**Procedure:** Boil off  $H_2S$  from the filtrate of II group or take original solution if first and second group radicals are absent. Add few drops of concentrated  $HNO_3$  and boil the solution. Add 10 g solid ammonium chloride and ammonium hydroxide slowly till the solution smells of ammonia. If the precipitate appears, filter. The filtrate should be kept for subsequent groups.

Reddish brown ppt. Fe(OH) <sub>3</sub>	Green precipitate Cr(OH) <sub>3</sub>	White precipitate Al(OH) <sub>3</sub>
Dissolve the ppt. in dilute HCl and divide into two parts:  Part I + K <sub>4</sub> Fe(CN) <sub>6</sub> soln.    Prussian blue solution or ppt. Part II + KCNS soln.    Red colouration.    Fe <sup>3+</sup> confirmed	ppt. + NaOH + Br <sub>2</sub> water → Yellow soln. Acidify the yellow solution with acetic acid and add lead acetate solution → Yellow ppt. Cr³+ confirmed	Dissolve the ppt. in dil. HCl. Add NaOH solution — White ppt. appears which then dissolves in excess of NaOH. Treat this solution with solid ammonium chloride — Gelatinous white
		precipitate.  Al <sup>3+</sup> confirmed

Note: (i) H<sub>2</sub>S must be completely removed, otherwise the sulphides of the IV group will be precipitated here.

(ii) A very small amount of HNO<sub>3</sub> should be used, otherwise manganese from divalent state (Mn<sup>2+</sup>) is oxidised to trivalent state (Mn<sup>3+</sup>) which may get precipitated as Mn(OH)<sub>3</sub>.

(iii) Precipitation should be done in hot condition and large excess of NH<sub>4</sub>OH should not be used. Ammonium chloride should always be added before the addition of ammonium hydroxide.

#### **GROUP IV**

**Radicals:** Ni<sup>2+</sup>, Co<sup>2+</sup>, Mn<sup>2+</sup>, Zn<sup>2+</sup>

Group reagent:  $H_2S$  gas in presence of  $NH_4Cl$  and  $NH_4OH$ 

**Procedure:** Take the filtrate of third group, concentrate it by heating. Add ammonium hydroxide and again heat the solution. Pass H<sub>2</sub>S gas. If the precipitate appears, pass H<sub>2</sub>S gas for sufficient time and then filter. Keep the filtrate for subsequent groups.

Black precipitate NiS or CoS	Buff coloured precipitate, MnS	White precipitate ZnS

Co <sup>2+</sup> confirmed		

#### GROUP V

Radicals: Ba<sup>2+</sup>, Sr<sup>2+</sup>, Ca<sup>2+</sup>

Group reagent: (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> in presence of NH<sub>4</sub>OH

**Procedure:** Take the filtrate of fourth group. Boil off H<sub>2</sub>S gas and concentrate to about 1/2 of its volume. Add a little solid NH<sub>4</sub>Cl and NH<sub>4</sub>OH followed by (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> solution. Appearance of white precipitate shows the presence of V group. Filter and keep the filtrate for VI group. The white precipitate may be either of BaCO<sub>3</sub> or SrCO<sub>3</sub> or CaCO<sub>3</sub>. Dissolve the precipitate in minimum quantity of acetic acid. Divide the solution into three parts.

1st part + K <sub>2</sub> CrO <sub>4</sub>	If Ba <sup>2+</sup> is absent, use	If Ba <sup>2+</sup> and Sr <sup>2+</sup> both
soln. → Yellow	2nd part. Add	are absent, use the 3rd
precipitate.	$(NH_4)_2SO_4$ solution	part.
Ba <sup>2+</sup> present	→ White precipitate.	Add $(NH_4)_2C_2O_4$
	Sr <sup>2+</sup> present	
-		Ca <sup>2+</sup> present

#### **GROUP VI**

Radical: Mg<sup>2+</sup>

Group reagent: Na<sub>2</sub>HPO<sub>4</sub> in presence of NH<sub>4</sub>OH

**Procedure:** Take the filtrate of V group and add a little NH<sub>4</sub>OH and then Na<sub>2</sub>HPO<sub>4</sub> solution. Scratch the walls of the test tube by a glass rod and allow to stand. Appearance of white precipitate confirms the presence of Mg<sup>2+</sup>.

**Test for NH** $_4^+$ : Take the mixture in a test tube and add 2-3 mL NaOH solution and heat. If the smell of NH $_3$  is observed, it confirms the presence of NH $_4^+$  ion. The confirmation can further be done by the following tests:

- (i) Bring a rod dipped in HCl near the mouth of test tube; white dense fumes are formed.
- (ii) Take aqueous solution of mixture and add Nessler's reagent. Appearance of brown colour or precipitate confirms the presence of NH<sub>4</sub><sup>+</sup> ion.

### 18.5 CHEMICAL REACTIONS INVOLVED IN THE TESTS OF BASIC RADICALS

#### **Group I**

When dil. HCl is added to original solution, insoluble chlorides of lead, silver and mercurous mercury are precipitated.

$$Pb(NO_3)_2 + 2HCl \longrightarrow PbCl_2 + 2HNO_3$$
  
 $AgNO_3 + HCl \longrightarrow AgCl + HNO_3$   
 $Hg_2(NO_3)_2 + 2HCl \longrightarrow Hg_2Cl_2 + 2HNO_3$ 

#### Pb<sup>2+</sup> (lead)

- (i) PbCl<sub>2</sub> is soluble in hot water and on cooling white crystals are again formed.
- (ii) The solution of PbCl<sub>2</sub> gives a yellow precipitate with potassium chromate solution which is insoluble in acetic acid but soluble in sodium hydroxide.

$$\begin{array}{c} PbCl_2 \, + \, K_2CrO_4 \longrightarrow & PbCrO_4 \, + \, 2KCl \\ & \quad \ Yellow \ ppt. \end{array}$$

$$PbCrO_4 + 4NaOH \longrightarrow Na_2PbO_2 + Na_2CrO_4 + 2H_2O$$

(iii) The solution of PbCl<sub>2</sub> forms a yellow precipitate with potassium iodide solution.

$$PbCl_2 + 2KI \longrightarrow PbI_2 + 2KCl$$
  
Yellow ppt.

(iv) White precipitate of lead sulphate is formed with dilute H<sub>2</sub>SO<sub>4</sub>. The precipitate is soluble in ammonium acetate.

$$PbCl_2 + H_2SO_4 \longrightarrow PbSO_4 + 2HCl$$
  
 $PbSO_4 + 2CH_3COONH_4 \longrightarrow Pb(CH_3COO)_2 + (NH_4)_2SO_4$ 

#### Ag<sup>+</sup> (silver)

(i) AgCl dissolves in ammonium hydroxide.

$$\begin{array}{c} AgCl + 2NH_4OH \longrightarrow Ag(NH_3)_2Cl + 2H_2O \\ \text{Diammine silver (I)} \\ \text{chloride} \end{array}$$

(ii) On adding dilute HNO<sub>3</sub> to the above solution, white precipitate is again obtained.

$$Ag(NH_3)_2Cl + 2HNO_3 \longrightarrow AgCl + 2NH_4NO_3$$
  
White ppt.

(iii) On adding KI to the complex solution, yellow precipitate is obtained.

$$Ag(NH_3)_2Cl + KI \longrightarrow AgI + KCl + 2NH_3$$
  
Yellow ppt.

#### Hg<sub>2</sub><sup>2+</sup> (mercurous)

(i) Hg<sub>2</sub>Cl<sub>2</sub> turns black with NH<sub>4</sub>OH.

$$Hg_2Cl_2 + 2NH_4OH \longrightarrow \underbrace{Hg + Hg(NH_2)Cl}_{Black} + NH_4Cl + 2H_2O$$

(ii) The black residue dissolves in aqua-regia forming mercuric chloride.

$$3HCl + HNO_3 \longrightarrow NOCl + 2H_2O + 2Cl$$
 $2Hg(NH_2)Cl + 6Cl \longrightarrow 2HgCl_2 + 4HCl + N_2$ 
 $Hg + 2Cl \longrightarrow HgCl_2$ 

(iii) The solution of HgCl<sub>2</sub> forms white or slate-coloured precipitate with stannous chloride.

$$2\text{HgCl}_2 + \text{SnCl}_2 \longrightarrow \text{Hg}_2\text{Cl}_2 + \text{SnCl}_4$$
White ppt.

 $\text{Hg}_2\text{Cl}_2 + \text{SnCl}_2 \longrightarrow 2\text{Hg} + \text{SnCl}_4$ 
Grey ppt.

(iv) The solution of HgCl<sub>2</sub> with copper turning forms a grey deposit.

$$HgCl_2 + Cu \longrightarrow Hg + CuCl_2$$
  
Grey ppt.

#### Group II

When hydrogen sulphide is passed in acidified solution, the radicals of second group are precipitated as sulphides. The precipitate is treated with yellow ammonium sulphide. The sulphides of IIB are first oxidised to higher sulphides which then dissolve to form thio-compounds.

$$\begin{array}{c} \text{As}_2\text{S}_3 \ + \ 2(\text{NH}_4)_2\text{S}_2 \ \longrightarrow \ 2(\text{NH}_4)_2\text{S} \ + \ \text{As}_2\text{S}_5 \\ \text{Sb}_2\text{S}_3 \ + \ 2(\text{NH}_4)_2\text{S}_2 \ \longrightarrow \ 2(\text{NH}_4)_2\text{S} \ + \ \text{Sb}_2\text{S}_5 \\ \text{SnS} \ + \ (\text{NH}_4)_2\text{S}_2 \ \longrightarrow \ (\text{NH}_4)_2\text{S} \ + \ \text{SnS}_2 \\ \text{As}_2\text{S}_5 \ + \ 3(\text{NH}_4)_2\text{S} \ \longrightarrow \ 2(\text{NH}_4)_3\text{AsS}_4 \\ \text{Ammonium thioarsenate} \\ \text{Sb}_2\text{S}_5 \ + \ 3(\text{NH}_4)_2\text{S} \ \longrightarrow \ 2(\text{NH}_4)_3\text{SbS}_4 \\ \text{Ammonium thioantimonate} \\ \text{SnS}_2 \ + \ (\text{NH}_4)_2\text{S} \ \longrightarrow \ (\text{NH}_4)_2\text{SnS}_3 \\ \text{Ammonium thiostannate} \\ \end{array} \right\} \text{Soluble}$$

In case, the precipitate does not dissolve in yellow ammonium sulphide, it may be either HgS or PbS or  $Bi_2S_3$  or CuS or CdS. The precipitate is heated with dilute HNO<sub>3</sub>. Except HgS, all other sulphides of IIA are soluble.

$$3PbS + 8HNO_3 \longrightarrow 3Pb(NO_3)_2 + 2NO + 3S + 4H_2O$$
  
 $Bi_2S_3 + 8HNO_3 \longrightarrow 2Bi(NO_3)_3 + 2NO + 3S + 4H_2O$ 

$$3\text{CuS} + 8\text{HNO}_3 \longrightarrow 3\text{Cu(NO}_3)_2 + 2\text{NO} + 3\text{S} + 4\text{H}_2\text{O}$$
  
 $3\text{CdS} + 8\text{HNO}_3 \longrightarrow 3\text{Cd(NO}_3)_2 + 2\text{NO} + 3\text{S} + 4\text{H}_2\text{O}$ 

#### Hg<sup>2+</sup> (mercuric)

HgS is dissolved in aqua-regia.

$$3HgS + 2HNO_3 + 6HCl \longrightarrow 3HgCl_2 + 3S + 2NO + 4H_2O$$

The solution is divided into two parts:

**Part I:** Stannous chloride solution reduces HgCl<sub>2</sub> first into white Hg<sub>2</sub>Cl<sub>2</sub> and then to grey metallic mercury.

Part II: Copper displaces Hg from HgCl<sub>2</sub> which gets coated on copper turnings as a shining deposit.

#### Pb<sup>2+</sup> (lead)

In case the sulphide dissolves in dilute HNO<sub>3</sub>, a small part of the solution is taken. Dilute H<sub>2</sub>SO<sub>4</sub> is added. If lead is present, a white precipitate of lead sulphate appears.

$$Pb(NO_3)_2 + H_2SO_4 \longrightarrow PbSO_4 + 2HNO_3$$
  
White ppt.

In absence of lead, the remaining solution is made alkaline by the addition of excess of NH<sub>4</sub>OH. Bismuth forms a white precipitate of Bi(OH)<sub>3</sub>, copper forms a deep blue coloured solution while cadmium forms a colourless soluble complex.

$$\begin{array}{c} \text{Bi(NO}_3)_3 + 3\text{NH}_4\text{OH} \longrightarrow & \text{Bi(OH)}_3 + 3\text{NH}_4\text{NO}_3 \\ & \text{White ppt.} \\ \text{Cu(NO}_3)_2 + 4\text{NH}_4\text{OH} \longrightarrow & [\text{Cu(NH}_3)_4](\text{NO}_3)_2 + 4\text{H}_2\text{O} \\ & \text{Tetrammine cupric nitrate} \\ & \text{(deep blue solution)} \end{array}$$

$$Cd(NO_3)_2 + 4NH_4OH \longrightarrow [Cd(NH_3)_4](NO_3)_2 + 4H_2O$$
Tetrammine cadmium nitrate (colourless solution)

#### Bi<sup>3+</sup> (bismuth)

The precipitate dissolves in dilute HCl.

$$Bi(OH)_3 + 3HCl \longrightarrow BiCl_3 + 3H_2O$$

**Part I:** Addition of excess of water to BiCl<sub>3</sub> solution gives a white precipitate due to hydrolysis.

$$BiCl_3 + H_2O \longrightarrow BiOCl + 2HCl$$
Bismuth
oxychloride
(White ppt.)

**Part II:** The solution of BiCl<sub>3</sub> is treated with sodium stannite solution when a black precipitate of metallic bismuth is formed.

$$2BiCl_3 + 3Na_2SnO_2 + 6NaOH \longrightarrow 3Na_2SnO_3 + 2Bi$$
  
Sod. stannite Sod. stannate  $+ 6NaCl + 3H_2O$ 

#### Cu<sup>2+</sup> (copper)

Blue coloured solution is acidified with acetic acid. When potassium ferrocyanide is added, a chocolate coloured precipitate is formed.

$$\begin{array}{c} \text{Cu(NH}_3)_4(\text{NO}_3)_2 + 4\text{CH}_3\text{COOH} \longrightarrow \text{Cu(NO}_3)_2 \\ + 4\text{CH}_3\text{COONH}_4 \\ 2\text{Cu(NO}_3)_2 + \text{K}_4[\text{Fe(CN)}_6] \longrightarrow \text{Cu}_2[\text{Fe(CN)}_6] + 4\text{KNO}_3 \\ & \text{Chocolate ppt.} \end{array}$$

#### Cd<sup>2+</sup> (cadmium)

H<sub>2</sub>S is passed through colourless solution. The appearance of yellow precipitate confirms the presence of cadmium.

$$Cd(NH_3)_4(NO_3)_2 + H_2S \longrightarrow CdS + 2NH_4NO_3 + 2NH_3$$
  
Yellow ppt.

#### 

In case the precipitate dissolves in yellow ammonium sulphide, the tests of the radicals arsenic, antimony and tin are performed. The sulphide is treated with concentrated hydrochloric acid. Antimony and tin sulphides dissolve while arsenic sulphide remains insoluble.

#### As<sup>3+</sup> (arsenic)

The insoluble sulphide is treated with concentrated nitric acid which is then heated with ammonium molybdate. Yellow precipitate of ammonium arsenomolybdate is formed.

$$(NH_4)_3AsO_4 \cdot 12MoO_3 + 21NH_4NO_3 + 12H_2O_4$$
  
Yellow ppt.

#### Sn<sup>2+</sup> or Sn<sup>4+</sup> (tin)

Solution of sulphide in concentrated HCl is reduced with iron fillings or granulated zinc.

$$SnS_2 + 4HCl \longrightarrow SnCl_4 + 2H_2S$$
  
 $SnCl_4 + Fe \longrightarrow SnCl_2 + FeCl_2$ 

HgCl<sub>2</sub> solution is added to above solution which gives first a white precipitate that turns to grey.

$$\begin{array}{ccc} 2 \text{HgCl}_2 + \text{SnCl}_2 & \longrightarrow & \text{Hg}_2 \text{Cl}_2 + \text{SnCl}_4 \\ & & \text{White ppt.} \\ \text{Hg}_2 \text{Cl}_2 + \text{SnCl}_2 & \longrightarrow & 2 \text{Hg} + \text{SnCl}_4 \\ & & & \text{Grev} \end{array}$$

#### Sb<sup>3+</sup>(antimony)

Filtrate of sulphide in concentrated HCl is divided into two parts:

**Part I:** On dilution with excess of water, a white precipitate of antimony oxychloride is obtained.

$$SbCl_3 + H_2O \longrightarrow SbOCl + 2HCl$$
White ppt.

**Part II :**  $H_2S$  is circulated. Orange precipitate is formed.  $2SbCl_3 + 3H_2S \longrightarrow Sb_2S_3 + 6HCl$ Orange ppt.

#### Group III

Hydroxides are precipitated on addition of excess of ammonium hydroxide in presence of ammonium chloride.

$$\begin{array}{c} AlCl_3 + 3NH_4OH \longrightarrow Al(OH)_3 + 3NH_4Cl \\ & Gelatinous \\ & ppt. \\ CrCl_3 + 3NH_4OH \longrightarrow Cr(OH)_3 + 3NH_4Cl \\ & Green ppt. \\ FeCl_3 + 3NH_4OH \longrightarrow Fe(OH)_3 + 3NH_4Cl \\ & Brownish \\ & red ppt. \end{array}$$

#### Fe<sup>3+</sup> (iron)

The brownish red precipitate dissolves in dilute HCl. The solution is divided into two parts:

**Part I :**  $K_4[Fe(CN)_6]$  solution is added which forms deep blue solution or precipitate.

$$Fe(OH)_3 + 3HCl \longrightarrow FeCl_3 + 3H_2O$$

$$4FeCl_3 + 3K_4[Fe(CN)_6] \longrightarrow Fe_4[Fe(CN)_6]_3 + 12KCl$$
Prussian blue

**Part II:** Addition of potassium thiocyanate solution gives a blood red colouration.

$$FeCl_3 + 3KCNS \longrightarrow Fe(CNS)_3 + 3KCl$$
Blood red colour

#### Cr<sup>3+</sup> (chromium)

The green precipitate is fused with fusion mixture  $(Na_2CO_3 + KNO_3)$ . The fused product is extracted with water or the precipitate is heated with NaOH and bromine water.

$$2\text{Cr}(\text{OH})_3 + 3\text{KNO}_3 + 2\text{Na}_2\text{CO}_3 \longrightarrow 2\text{Na}_2\text{CrO}_4 + 3\text{KNO}_2 \\ + 2\text{CO}_2 + 3\text{H}_2\text{O}$$
 or 
$$2\text{NaOH} + \text{Br}_2 \longrightarrow \text{NaBrO} + \text{NaBr} + \text{H}_2\text{O}$$
 
$$\text{NaBrO} \longrightarrow \text{NaBr} + [\text{O}]$$
 
$$2\text{Cr}(\text{OH})_3 + 4\text{NaOH} + 3[\text{O}] \longrightarrow 2\text{Na}_2\text{CrO}_4 + 5\text{H}_2\text{O}$$

The solution thus obtained contains sodium chromate. The solution is acidified with acetic acid and treated with lead acetate solution. A yellow precipitate appears.

$$Na_2CrO_4 + Pb(CH_3COO)_2 \longrightarrow PbCrO_4 + 2CH_3COONa$$
  
Yellow ppt.

#### Al<sup>3+</sup> (aluminium)

The gelatinous precipitate dissolves in NaOH.

$$Al(OH)_3 + NaOH \longrightarrow NaAlO_2 + 2H_2O$$
Soluble

The solution is boiled with ammonium chloride when Al(OH)<sub>3</sub> is again formed.

$$NaAlO_2 + NH_4Cl + H_2O \longrightarrow Al(OH)_3 + NaCl + NH_3$$

#### Group IV

On passing H<sub>2</sub>S through the filtrate of the third group, sulphides of fourth group are precipitated. NiS and CoS are black and insoluble in concentrated HCl while MnS (buff coloured), ZnS (colourless) are soluble in conc. HCl.

#### Zn<sup>2+</sup> (zinc)

The sulphide dissolves in HCl.

$$ZnS + 2HCl \longrightarrow ZnCl_2 + H_2S$$

When the solution is treated with NaOH, first a white precipitate appears which dissolves in excess of NaOH.

$$ZnCl_2 + 2NaOH \longrightarrow Zn(OH)_2 + 2NaCl$$

White ppt.

 $Zn(OH)_2 + 2NaOH \longrightarrow Na_2ZnO_2 + 2H_2O$ 
(Soluble)

On passing H<sub>2</sub>S, white precipitate of zinc sulphide is formed.

$$Na_2ZnO_2 + H_2S \longrightarrow ZnS + 2NaOH$$
  
White ppt.

#### Mn<sup>2+</sup> (manganese)

Manganese sulphide dissolves in HCl.

$$MnS + 2HCl \longrightarrow MnCl_2 + H_2S$$

On heating the solution with NaOH and Br<sub>2</sub>-water, manganese dioxide gets precipitated.

$$MnCl_2 + 2NaOH \longrightarrow Mn(OH)_2 + 2NaCl$$
  
 $Mn(OH)_2 + O \longrightarrow MnO_2 + H_2O$ 

The precipitate is treated with excess of nitric acid and PbO<sub>2</sub> or Pb<sub>3</sub>O<sub>4</sub> (red lead). The contents are heated. The formation of permanganic acid imparts pink colour to the supernatant liquid.

$$2MnO_2 + 4HNO_3 \longrightarrow 2Mn(NO_3)_2 + 2H_2O + O_2$$
  
 $2Mn(NO_3)_2 + 5Pb_3O_4 + 26HNO_3 \longrightarrow 2HMnO_4$   
Permanganic acid (pink)  
 $+ 15Pb(NO_3)_2 + 12H_2O$ 

Note: The above test fails in presence of HCl.

#### Ni<sup>2+</sup> (nickel) and Co<sup>2+</sup> (cobalt)

The black precipitate is dissolved in aqua-regia.

$$3NiS + 6HCl + 2HNO_3 \longrightarrow 3NiCl_2 + 2NO + 3S + 4H_2O$$
  
 $3CoS + 6HCl + 2HNO_3 \longrightarrow 3CoCl_2 + 2NO + 3S + 4H_2O$ 

The solution is evaporated to dryness and residue extracted with dilute HCl. It is divided into three parts:

**Part I:** Add NH<sub>4</sub>OH (excess) and dimethyl glyoxime. A rosy red precipitate appears, if nickel is present.

$$\begin{array}{c|c} CH_3-C=NOH \\ NiCl_2+2 & | +2NH_4OH \longrightarrow \\ CH_3-C=NOH \\ OH & O \\ | & \uparrow \\ CH_3-C=N \\ | & N=C-CH_3 \\ | & +2NH_4Cl+2H_2O \\ | & N=C-CH_3 \\ | & O \end{array}$$

Part II: Add CH<sub>3</sub>COOH in excess and KNO<sub>2</sub>. The appearance of yellow precipitate confirms the presence of cobalt.

$$KNO_2 + CH_3COOH \longrightarrow CH_3COOK + HNO_2$$

$$CoCl_2 + 2KNO_2 \longrightarrow Co(NO_2)_2 + 2KCl$$

$$Co(NO_2)_2 + 2HNO_2 \longrightarrow Co(NO_2)_3 + NO + H_2O$$

$$Co(NO_2)_3 + 3KNO_2 \longrightarrow K_3[Co(NO_2)_6]$$

**Part III:** Solution containing either nickel or cobalt is treated with NaHCO<sub>3</sub> and bromine water. Appearance of apple green colour confirms the presence of cobalt. If no apple green colour is observed, the solution is heated when black precipitate is formed, which shows the presence of nickel.

$$\begin{array}{c} CoCl_2 + 2NaHCO_3 \longrightarrow Co(HCO_3)_2 + 2NaCl \\ Co(HCO_3)_2 + 4NaHCO_3 \longrightarrow Na_4Co(CO_3)_3 + 3H_2O + 3CO_2 \\ Br_2 + H_2O \longrightarrow 2HBr + O \\ \\ 2Na_4Co(CO_3)_3 + H_2O + O \longrightarrow 2Na_3Co(CO_3)_3 + 2NaOH \\ Sod. \ cobalticarbonate \ (Green \ colouration) \\ NiCl_2 + 2NaHCO_3 \longrightarrow NiCO_3 + 2NaCl + H_2O + CO_2 \\ 2NiCO_3 + O \longrightarrow Ni_2O_3 + 2CO_2 \\ (Black) \end{array}$$

#### Group V

Ammonium carbonate precipitates V group radicals in the form of carbonates. These carbonates are soluble in acetic acid.

$$BaCO_3 + 2CH_3COOH \longrightarrow (CH_3COO)_2Ba + CO_2 + H_2O$$
  
 $SrCO_3 + 2CH_3COOH \longrightarrow (CH_3COO)_2Sr + CO_2 + H_2O$   
 $CaCO_3 + 2CH_3COOH \longrightarrow (CH_3COO)_2Ca + CO_2 + H_2O$ 

#### Ba<sup>2+</sup> (barium)

Barium chromate is insoluble and precipitated by the addition of potassium chromate solution.

$$Ba(CH_3COO)_2 + K_2CrO_4 \longrightarrow BaCrO_4 + 2CH_3COOK$$

#### Sr<sup>2+</sup> (strontium)

Strontium sulphate is insoluble and precipitated by the addition of ammonium sulphate solution.

$$\begin{array}{c} Sr(CH_3COO)_2 \ + \ (NH_4)_2SO_4 \longrightarrow SrSO_4 \ + \ 2CH_3COONH_4 \\ & White \ ppt. \end{array}$$

#### Ca<sup>2+</sup> (calcium)

Calcium oxalate is insoluble and precipitated by the addition of ammonium oxalate.

$$Ca(CH_3COO)_2 + (NH_4)_2C_2O_4 \longrightarrow CaC_2O_4 + 2CH_3COONH_4$$
 White ppt.

#### **Group VI**

In the filtrate of V-group, some quantity of ammonium oxalate is added as to remove Ba, Ca and Sr completely from the solution. The clear solution is concentrated and made alkaline with NH<sub>4</sub>OH. Disodium hydrogen phosphate is now added, a white precipitate is formed.

$$MgCl_2+Na_2HPO_4+NH_4OH \longrightarrow Mg(NH_4)PO_4+2NaCl+H_2O$$

Magnesium ammonium

phosphate

(White ppt.)

#### NH4 (ammonium)

The substance (salt or mixture) when heated with NaOH solution evolves ammonia.

$$NH_4Cl + NaOH \longrightarrow NaCl + NH_3 + H_2O$$

When a rod dipped in HCl is brought on the mouth of the test-tube, white fumes of ammonium chloride are formed.

$$NH_3 + HCI \longrightarrow NH_4CI$$
White fumes

To the aqueous solution of ammonium salt when Nessler's reagents is added, brown coloured precipitate is formed.

$$2K_{2}HgI_{4} + NH_{4}Cl + 4KOH \longrightarrow Hg O + 7KI + KCl + 3H_{2}O$$

$$I$$

$$Iodide of Millon's base (Brown ppt.)$$

#### 18.6 DRY TESTS

Dry tests are of great importance as these tests give clear indications of the presence of certain radicals. The following tests are performed in dry state:

- (i) Flame test
- (ii) Borax bead test
- (iii) Microcosmic salt bead test
- (iv) Charcoal cavity test
- (v) Cobalt nitrate charcoal test

#### (i) Flame test

Some volatile salts impart characteristic colour to the non-luminous flame. The chlorides of the metals are more volatile in comparison to other salts. The metal chloride volatilises and its thermal ionisation takes place.

$$NaCl \implies Na^+ + Cl^-$$
  
 $CaCl_2 \implies Ca^{2+} + 2Cl^-$ 

The cations impart a characteristic colour to the flame as these absorb energy from the flame and transmit the same as light of characteristic colour.

**Procedure:** The platinum wire fused in a glass rod is heated in the flame till it imparts colourless flame. This is achieved by dipping the wire in conc. HCl and heating it. The process is repeated till it gives a colourless flame. The tip of the wire is now dipped in conc. HCl and then into the substance. The tip of the wire is strongly heated in the non-luminous flame and the colour of the flame is observed by the naked eye.

Colour of flame	Inference
<ol> <li>Golden yellow</li> </ol>	Sodium
2. Violet	Potassium
3. Brick red	Calcium
4. Crimson red	Strontium
5. Apple green	Barium
6. Green with a blue centre	Copper

Note: Flame test should not be performed in the presence of As, Sb, Bi, Sn and Pb as these radicals form alloy with platinum and hence, the wire is spoiled.

#### (ii) Borax bead test

On heating borax the colourless glassy bead formed consists of sodium metaborate and boric anhydride.

$$Na_2B_4O_7 \cdot 10H_2O \xrightarrow{Heat} Na_2B_4O_7 \xrightarrow{Heat} \underbrace{2NaBO_2 + B_2O_3}_{Glassy bead}$$

On heating with a coloured salt, the glassy bead forms a coloured metaborate in oxidising flame.

$$\begin{array}{c} CuSO_4 \longrightarrow CuO + SO_3 \\ CuO + B_2O_3 \longrightarrow Cu(BO_2)_2 \\ \hline Copper metaborate \\ \hline (Blue) \end{array}$$

The metaborates possess different characteristic colours. The shade of the colour gives a clue regarding the presence of the radical.

However, in reducing flame the colours may be different due to different reactions. For example, copper metaborate may be reduced to colourless cuprous metaborate or to metallic copper, which appears red and opaque.

$$2Cu(BO_2)_2 + C \longrightarrow 2CuBO_2 + B_2O_3 + CO$$
  
 $2Cu(BO_2)_2 + 2C \longrightarrow 2Cu + 2B_2O_3 + 2CO$ 

**Procedure:** The free end of a platinum wire is coiled into a small loop and heated in the Bunsen flame until red hot. It is dipped in borax and again heated, when borax swells up and then fused into a glassy bead.

The bead is moistened with water and dipped in the coloured salt. It is now heated first in the oxidising flame and then in the reducing flame and colours are noted in both the flames in hot and cold conditions.

	Colour of the bead in							
Metal	Oxidisin	g flame	Reducing flame					
	Hot Cold		Hot	Cold				
Copper	Green	Blue	Colourless	Brown-red				
Iron	Brown-yellow	Pale-yellow	Bottle green	Bottle green				
Chromium	Green	Green	Green	Green				
Cobalt	Blue	Blue	Blue	Blue				
Manganese	Violet	Amethyst red	Grey	Grey				
Nickel	Violet	Brown	Grey	Grey				

#### (iii) Microcosmic salt bead test

This test is similar to borax bead test. When microcosmic salt is heated, a colourless transparent bead of sodium metaphosphate is formed.

$$Na(NH_4)HPO_4 \longrightarrow NaPO_3 + NH_3 + H_2O$$
Sodium
metaphosphate

Sodium metaphosphate combines with metallic oxides to form orthophosphates which are usually coloured. The shade of the colour gives a clue regarding the presence of metal. Like borax bead test, colours are noted both in oxidising and reducing flames in hot and cold conditions.

	Colour of the bead in						
Metal	Oxidisin	g flame	Reducing flame				
	Hot Cold		Hot	Cold			
Copper	Green	Blue	Colourless	Red			
Iron	Yellow or	Yellow	Yellow	Colourless			
	reddish-brown						
Chromium	Green	Green	Green	Green			
Manganese	Violet	Violet	Colourless	Colourless			
Cobalt	Blue	Blue	Blue	Blue			
Nickel	Brown	Brown	-	Grey			

#### (iv) Charcoal cavity test

This test is carried out on a charcoal block in which a small cavity has been made by a knife. About 0.1 g of the substance is mixed with 0.2 g of anhydrous Na<sub>2</sub>CO<sub>3</sub> or fusion mixture and the mixture is placed in the cavity. The mass is moistened with a drop of water and heated in a reducing flame with the

blow pipe. The bead or incrustation formed is observed. When metallic salt is heated with Na<sub>2</sub>CO<sub>3</sub>, the metal carbonate is formed which decomposes into oxide. The carbon of the block reduces the oxide into metal. For example,

$$CuCl_2 + Na_2CO_3 \longrightarrow CuCO_3 + 2NaCl$$
 $CuCO_3 \longrightarrow CuO + CO_2$ 
 $CuO + C \longrightarrow Cu + CO$ 

Observation	Inference
1. Formation of metallic bead :	
(a) Lustrous white, malleable	Ag
(b) Greyish white, marks paper	Pb
(c) White, does not mark paper	Sn
(d) Red	Cu
2. Incrustation with metal:	
(a) White incrustation, brittle metal	Sb
(b) Yellow incrustation, brittle metal	Bi
(c) Yellow incrustation, malleable metal	Pb
3. Incrustation without metal:	
(a) White and yellow when hot	ZnO, SnO
(b) Yellow and orange when hot	BiO
(c) Brown	CdO
(d) White (volatile, garlic odour)	As <sub>2</sub> O <sub>3</sub>

#### (v) Cobalt nitrate charcoal test

A small amount of the substance and twice its bulk of sodium carbonate is placed in the charcoal cavity. A drop of water is added and the mass is heated in an oxidising flame with the help of blow pipe. After cooling, one or two drops of cobalt nitrate solution are added and the mass is again heated in the oxidising flame. The colour produced in the cavity is noted.

By heating the salt with sodium carbonate, the oxide is formed which on heating with cobalt nitrate form a mixed oxide of a characteristic colour.

$$ZnSO_4 + Na_2CO_3 \longrightarrow ZnCO_3 + Na_2SO_4$$
 $ZnCO_3 \longrightarrow ZnO + CO_2$ 
 $2Co(NO_3)_2 \longrightarrow 2CoO + 4NO_2 + O_2$ 
 $ZnO + CoO \longrightarrow CoZnO_2$ 
Rinnmann green

Observation	Inference
(a) Blue mass	Aluminium
(b) Green residue	Zinc
(c) Pink residue	Magnesium
(d) Bluish-green	- Tin

### 50ME-50LVED-PROBLEMS

**Problem 1.** Two solid laboratory reagents 'A' and 'B' give the following reactions:

#### Compound A:

- (i) On strongly heating it gives two oxides of sulphur.
- (ii) On adding aqueous NaOH solution to its aqueous solution a dirty green precipitate is obtained, which starts turning brown on exposure to air.

#### Compound B:

- (iii) It imparts green colour to the flame.
- (iv) Its solution does not give a precipitate on passing  $H_2S$ .
- (v) When it is heated with solid  $K_2Cr_2O_7$  and concentrated  $H_2SO_4$ , a red gas is evolved. The gas when passed in an aqueous solution of NaOH, turns it yellow.

Identify 'A' and 'B'.

[Roorkee 1993]

#### **Solution:**

**Compound A:** (i) Compound 'A' is ferrous sulphate which gives  $SO_2$  and  $SO_3$  on heating.

(ii) Ferrous sulphate gives dirty green Fe(OH)<sub>2</sub> with aqueous NaOH.

$$FeSO_4 + 2NaOH \longrightarrow Fe(OH)_2 + Na_2SO_4$$
(Dirty green)

Fe(OH)<sub>2</sub> turns brown on oxidation, when exposed to atmosphere.

$$2\text{Fe}(\text{OH})_2 + \text{H}_2\text{O} + \frac{1}{2}\text{O}_2 \longrightarrow 2\text{Fe}(\text{OH})_3$$
Brown

**Compound B:** (iii) and (iv) Compound 'B' is  $BaCl_2$  which imparts green colour to flame and does not give any precipitate with  $H_2S$ .

(v)  $BaCl_2$  forms chromyl chloride, when treated with  $K_2Cr_2O_7$  and conc.  $H_2SO_4$ .

$$2BaCl_2 + K_2Cr_2O_7 + 3H_2SO_4 \longrightarrow$$

$$K_2SO_4 + 2BaSO_4 + 2CrO_2Cl_2 + 3H_2O$$
  
Chromyl chloride

(Red gas)

Chromyl chloride forms, yellow coloured Na<sub>2</sub>CrO<sub>4</sub> with aqueous NaOH.

$$CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O$$
Yellow
(Sodium chromate)

**Problem 2.** A light green crystalline compound responds to the following test:

- (i) Its aqueous solution gives a brown precipitate or colouration with alkaline  $K_2HgI_4$  solution.
- (ii) Its aqueous solution gives a blue colour with  $K_3Fe(CN)_6$  solution.
- (iii) Its solution in hydrochloric acid gives a white precipitate with BaCl<sub>2</sub> solution. Identify the ions present and suggest the formula of the compound. [J.I.T. 1992]

#### **Solution:**

- (i) K<sub>2</sub>HgI<sub>4</sub> is called Nessler's reagent. It is specially used to check the presence of NH<sub>4</sub><sup>+</sup>; giving brown precipitate. Hence, compound contains NH<sub>4</sub><sup>+</sup> ion.
- (ii) With K<sub>3</sub>Fe(CN)<sub>6</sub>, only Fe<sup>2+</sup> ion gives blue colour called Turnbull's blue.
- (iii) BaCl<sub>2</sub> gives white precipitate with  $SO_4^{2-}$  ions. Hence, compound (X) would be Mohr's salt. FeSO<sub>4</sub>(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>·6H<sub>2</sub>O which contains all the three ions.

**Problem 3.** An aqueous solution of gas (X) shows the following reactions:

- (i) It turns red litmus blue.
- (ii) When added in excess to a copper sulphate solution, a deep blue colour is obtained.
- (iii) On addition of FeCl<sub>3</sub> solution, a brown precipitate, soluble in dilute  $HNO_3$  is obtained. Identify (X) and give equations for the reactions at step (ii) and (iii).

Roorkee 1991]

#### **Solution:**

Gas 'X' is soluble in water forming basic solution because it turns red litmus blue. Hence, the gas may be NH<sub>3</sub>.

$$NH_3 + H_2O \longrightarrow NH_4OH$$
 $CuSO_4 + 4NH_4OH \longrightarrow [Cu(NH_3)_4]SO_4 + 4H_2O$ 
(Tetraamine cupric sulphate)
Deep blue complex

Ferric chloride gives brown precipitate of Fe(OH)<sub>3</sub>.

 $FeCl_3 + 3NH_4OH \longrightarrow Fe(OH)_3 + 3NH_4Cl$ (Brown precipitate)

Brown precipitate is soluble in HNO<sub>3</sub>.

**Problem 4.** A certain compound (X) is used in laboratory for analysis, its aqueous solution gives the following reactions:

- (i) On adding copper sulphate, a brown precipitate is obtained which turns white on addition of excess of  $Na_2S_2O_3$  solution.
- (ii) On addition of  $Ag^+$  ion solution a yellow curdy precipitate is obtained which is insoluble in ammonium hydroxide.

Identify (X) and give equations for the reactions at step (i) and (ii). [Roorkee 1991]

#### **Solution:**

Yellow curdy precipitate with Ag<sup>+</sup> confirms the presence of I<sup>-</sup> ion in the compound. The precipitate is insoluble in NH<sub>4</sub>OH.

$$Ag^+ + I^- \longrightarrow AgI$$

Compound (X) gives brown precipitate with CuSO<sub>4</sub> which becomes white when Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> is added. Thus, compound (X) should be KI. Reactions involved may be given as:

$$\begin{array}{c} \text{CuSO}_4 + 2\text{KI} & \longrightarrow & \text{CuI}_2 + \text{K}_2\text{SO}_4 \\ 2\text{CuI}_2 & \longrightarrow & \text{Cu}_2\text{I}_2 & + \text{I}_2 \\ & \text{White} & \text{Brown} \\ & & & & & & \\ (\text{Insoluble}) & \\ 2\text{Na}_2\text{S}_2\text{O}_3 + \text{I}_2 & \longrightarrow & \text{Na}_2\text{S}_4\text{O}_6 + 2\text{NaI} \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & & \\ & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & &$$

After removal of iodine, white precipitate of  $Cu_2I_2$  appears as both  $Na_2S_4O_6$  and NaI form colourless solution.

**Problem 5.** A compound on heating with an excess of caustic soda solution liberates a gas (B) which gives white fumes on exposure of HCl. Heating it continued to expel the gas completely. The resultant alkaline solution again liberates the same gas (B) when heated with zinc powder. However the compound (A), when heated alone does not give nitrogen. Identify (A) and (B).

#### **Solution:**

Gas (B) gives white fumes with HCl, hence it should be NH<sub>3</sub>. Thus, compound (A) must be an ammonium salt.

We know that nitrates and nitrites on heating with Zn and alkali liberate NH<sub>3</sub> gas. Hence, the compound (A) should be ammonium nitrate or nitrite. But compound (A) does not give N<sub>2</sub> on heating, hence it may not be ammonium nitrite.

#### Reactions involved:

$$NH_4NO_3 + NaOH \longrightarrow NaNO_3 + H_2O + NH_3 \uparrow$$
 $(A)$ 
 $NH_3 + HCl \longrightarrow NH_4Cl$ 
 $(White fumes)$ 
 $NaNO_3 + 8[H] \xrightarrow{Zn/NaOH} NaOH + 2H_2O + NH_3 \uparrow$ 

**Problem 6.** An unknown solid mixture contains one or two of the following: CaCO<sub>3</sub>, BaCl<sub>2</sub>, AgNO<sub>3</sub>, Na<sub>2</sub>SO<sub>4</sub>, ZnSO<sub>4</sub> and NaOH. The mixture is completely soluble in water and the solution gives pink colour with phenolphthalein. When dilute hydrochloric acid is gradually added to above solution, a precipitate is formed which dissolves with further addition of the acid. What is/are present in the solid?

Give equations to explain the appearance of the precipitate—and its dissolution.

#### **Solution:**

- (i) Mixture gives pink colour with phenolphthalein, hence it should contain NaOH.
- (ii) Aqueous solution gives precipitate with dil. HCl which dissolves in excess HCl. It means that compound is zinc salt.

Thus, the mixture should be of NaOH and ZnSO<sub>4</sub>. Reactions involved may be given as:

$$ZnSO_4 + 4NaOH \longrightarrow Na_2ZnO_2 + Na_2SO_4 + 2H_2O$$
Sodium zincate
 $Na_2ZnO_2 + 2HCl \longrightarrow 2NaCl + Zn(OH)_2 \downarrow$ 
White ppt.

 $Zn(OH)_2 + 2HCl \longrightarrow ZnCl_2 + 2H_2O$ 
Soluble

Hence, NaOH and ZnSO<sub>4</sub> are present in the solid.

**Problem 7.** The gas liberated on heating a mixture of two salts with NaOH, gives a reddish brown precipitate with an alkaline solution of  $K_2HgI_4$ . The aqueous solution of mixture on treatment with  $BaCl_2$  gives a white precipitate which is sparingly soluble in conc. HCl. On heating the mixture with  $K_2Cr_2O_7$  and conc.  $H_2SO_4$ , red vapours (A) are produced. The aqueous solution of mixture gives a deep blue calouration (B) with potassium ferricyanide. Identify the radicals in given mixture and write the balanced equation for formation of (A) and (B). [I.I.T. 1991]

#### **Solution:**

- (i) Gas given by heating mixture with NaOH gives brown ppt. with Nessler's reagent K<sub>2</sub>HgI<sub>4</sub>. It shows that the salt is a ammonium salt.
- (ii) BaCl<sub>2</sub> solution gives white precipitate sparingly soluble in HCl. It shows the presence of  $SO_4^2$  ion in the mixture.
- (iii) Blue colour with  $K_3Fe(CN)_6$  indicates the presence of  $Fe^{2+}$  ion.

(iv) Mixture + 
$$K_2Cr_2O_7 \xrightarrow{H_2SO_4} Red vapours (CrO_2Cl_2)$$
(A)

It shows that the mixture contains Cl<sup>-</sup> ion. Reactions involved may be given as:

(i) 
$$NH_4Cl + NaOH \xrightarrow{\Delta} NaCl + NH_3 \uparrow + H_2O$$
  
 $K_2HgI_4 + NaOH + NH_3 \rightarrow O \xrightarrow{Hg} NH_2I + KI + H_2O + NaI$   
(Brown ppt.)

(ii) 
$$FeSO_4 + BaCl_2 \longrightarrow BaSO_4 + FeCl_2$$
(White ppt.)

(iii) 
$$3\text{FeSO}_4 + 2\text{K}_3\text{Fe}(\text{CN})_6 \longrightarrow 3\text{K}_2\text{SO}_4 + \text{Fe}_3[\text{Fe}(\text{CN})_6]_2$$
  
Ferrous ferricyanide (Blue)

(iv) 
$$4NH_4Cl + K_2Cr_2O_7 + 3H_2SO_4 \longrightarrow 2CrO_2Cl_2 + K_2SO_4$$
  
Chromyl chloride  $+ 3H_2O + 2(NH_4)_2SO_4$ 

**Problem 8.** A colourless solid (A) liberates a brown gas (B) on acidification, a colourless alkaline gas (C) on treatment with NaOH, and a colourless non-reactive gas (D) on heating. If heating of the solid continued, it completely disappears. Identify (A) to (D).

#### Solution:

Alkaline gas (C) with NaOH indicate that solid should be ammonium salt. Heating the salt, a colourless gas (D) non-reactive is formed. The gas (D) may be nitrogen. The compound may thus be NH<sub>4</sub>NO<sub>2</sub>. Reactions involved may be given as:

(i) 
$$NH_4NO_2 \xrightarrow{HCl} NH_4Cl + HNO_2$$

$$(A) \qquad \qquad 2HNO_2 \longrightarrow H_2O + 2NO + [O]$$

$$2NO + 2[O] \longrightarrow 2NO_2$$

$$(B) Brown gas$$

(ii) 
$$NH_4NO_2 + NaOH \longrightarrow NaNO_2 + H_2O + NH_3 \uparrow$$
(C)

(iii) 
$$NH_4NO_2 \xrightarrow{\text{Heat}} N_2 \uparrow + 2H_2O \uparrow$$
(A) (D)

**Problem 9.** An aqueous solution of gas (X) gives the following reactions:

- (i) It decolourizes an acidified  $K_2Cr_2O_7$  solution.
- (ii) On boiling it with  $H_2O_2$ , cooling it and then adding an aqueous solution of  $BaCl_2$  a precipitate insoluble in dil. HCl is obtained.
- (iii) On passing  $H_2S$  in the solution, a white turbidity is obtained.

Identify (X) and give equations for the reactions at steps (i), (ii) and (iii). [Roorkee 1990]

#### Solution:

The reactions given in (i), (ii) and (iii) may be explained if we consider the gas (X) to be  $SO_2$ .

(i) 
$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$

(ii) 
$$H_2O + SO_2 + [O] \longrightarrow H_2SO_4$$
  
 $H_2O_2 + SO_2 \longrightarrow H_2SO_4$   
 $H_2SO_4 + BaCl_2 \longrightarrow BaSO_4 + 2HCl$   
(White ppt.)

**Problem 10.** A black coloured compound (A) on reaction with dil.  $H_2SO_4$  gives a gas (B) which on passing in a solution of an acid (C) gives a white turbidity (D). Gas (B) when passed in acidified solution of (E) gives a precipitate (F) soluble in dilute HNO3. After boiling this solution when excess of  $NH_4OH$  is added, a blue coloured compound (G) is formed. To this solution on addition of acetic acid and aqueous potassium ferrocyanide a chocolate coloured precipitate (H) is obtained. On addition of an aqueous solution of  $BaCl_2$  to an aqueous solution of (E), a white precipitate insoluble in  $HNO_3$  is obtained. Identify (A) to (H). [Roorkee 1987]

#### Solution:

Flow diagram of the reaction may be given as:

$$A \text{ [Black]} \xrightarrow{\text{H}_2\text{SO}_4} B \text{ (gas)} \xrightarrow{\text{Acid}} \text{Turbidity } (D)$$

$$A \text{ (ad soln. of } (E)$$

$$\downarrow \qquad \qquad \qquad \downarrow \qquad$$

E (aqueous solution)  $\xrightarrow{\operatorname{BaCl}_2}$  White precipitate insoluble in

HNO<sub>3</sub>

#### Reactions involved may be given as:

FeS + 
$$H_2SO_4 \longrightarrow FeSO_4 + H_2S$$
Ferrous sulphide
Black (A)

 $H_2S + 2HNO_3 \longrightarrow 2NO_2 + 2H_2O + S \uparrow$ 
(B)
(C)
Colloidal sulphur
(D) (Turbid)

$$CuSO_4 + H_2S \xrightarrow{HCl} CuS + H_2SO_4$$
Precipitate
(F)

 $3CuS + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 2NO + 3S + 4H_2O$ 
(F)

$$Cu(NO_3)_2 + H_2SO_4 \longrightarrow CuSO_4 + 2HNO_3$$

$$CuSO_4 + 4NH_4OH \longrightarrow [Cu(NH_3)_4]SO_4 + 4H_2O$$
(Deep blue)
(G)

$$[Cu(NH_3)_4]SO_4 + 4CH_3COOH \longrightarrow CuSO_4 + 4CH_3COONH_4$$

$$\begin{array}{c} CuSO_4 + BaCl_2 \longrightarrow & BaSO_4 + CuCl_2 \\ & \text{White ppt.} \\ & \text{insoluble in HNO}_3 \end{array}$$

$$2\text{CuSO}_4 + \text{K}_4\text{Fe}(\text{CN})_6 \longrightarrow \text{Cu}_2[\text{Fe}(\text{CN})_6] + 2\text{K}_2\text{SO}_4$$
Cupric ferrocyanide
(Chocolate precipitate)

**Problem 11.** Give the complete balanced equation for the following:

- (i) Mercurous nitrate reacts with excess KI solution.
- (ii) Sodium chromite solution reacts with  $H_2O_2$  in presence of NaOH.
- (iii) Nickel sulphate reacts with dimethyl glyoxime reagent in ammonical solution. [M.L.N.R. 1997]

#### **Solution:**

(i) 
$$Hg_2(NO_3)_2 + 2KI \longrightarrow Hg_2I_2 + 2KNO_3$$
  
 $Hg_2I_2 + 2KI \longrightarrow K_2HgI_4 + Hg$ 

(ii) 
$$Na_2CrO_2 + 2H_2O_2 \longrightarrow Na_2CrO_4 + H_2O$$

(iii) NiSO<sub>4</sub> + 2 
$$CH_3$$
—C=NOH  $+ 2NH_4OH \longrightarrow CH_3$ —C=NOH

**Problem 12.** (i) The yellow coloured precipitate of compound (A) is formed on passing  $H_2S$  through a neutral solution of salt (B).

- (ii) (A) is soluble in hot dilute  $HNO_3$  but insoluble in yellow ammonium sulphide.
- (iii) The solution of (B) on treatment with small quantity of  $NH_3$  gives white precipitate which becomes soluble in excess of it forming a compound (C).

- (iv) The solution of (B) gives white precipitate with small concentration of KCN which becomes soluble in excess of this reagent forming a compound (D).
  - (v) The solution of (D) on treatment with  $H_2S$  gives (A).
- (vi) The solution of (B) in dil. HCl on treatment with a solution of BaCl<sub>2</sub> gives white precipitate of compound (E) which is insoluble in conc. HNO<sub>3</sub>.

Identify (A) to (E) and give chemical equations for the reactions at steps (i) to (iii) to (vi). [Roorker 1998]

#### Solution:

Yellow precipitate of CdS is (A).

(i) 
$$CdSO_4 + H_2S \longrightarrow CdS + H_2SO_4$$
(B)  $(A)$ 

(ii) 
$$CdS + 2HNO_3 \longrightarrow Cd(NO_3)_2 + H_2S$$
  
Soluble

CdS - Insoluble in yellow ammonium sulphide.

$$CdSO_4 + 2NH_4OH \longrightarrow Cd(OH)_2 + (NH_4)_2SO_4$$

(iii) 
$$Cd(OH)_2 + 4NH_4OH \longrightarrow [Cd(NH_3)_4](OH)_2 + 4H_2O$$

(iv) 
$$CdSO_4 + 2KCN \longrightarrow Cd(CN)_2 + K_2SO_4$$

$$\frac{White}{Cd(CN)_2 + 2KCN \longrightarrow K_2[Cd(CN)_4]}$$
(D) Soluble

(v) 
$$K_2[Cd(CN)_4] + H_2S \longrightarrow CdS + 2KCN + 2HCN$$

(vi) 
$$CdSO_4 + BaCl_2 \longrightarrow BaSO_4 + CdCl_2$$
(E)

White precipitate insoluble in HNO<sub>3</sub>.

**Problem 13.** (i) An aqueous solution of a compound (A) is acidic towards litmus and (A) is sublimed at about 300°C.

- (ii) (A) on treatment with an excess of NH<sub>4</sub>SCN gives a red coloured compound (B) and on treatment with a solution of  $K_4[Fe(CN)_6]$  gives a blue coloured compound (C).
- (iii) (A) on heating with excess of  $K_2Cr_2O_7$  in presence of concentrated  $H_2SO_4$  evolves deep red vapours of (D).
- (iv) On passing the vapours of (D) into a solution of NaOH and then adding the solutions of acetic acid and lead acetate, a yellow precipitate of compound (E) is obtained.

Identify (A) to (E) and give chemical equations for the reactions at steps (ii) to (iv). [Roorkee 1998]

#### **Solution:**

(i) 
$$\operatorname{FeCl}_3 + 3H_2O \longrightarrow \operatorname{Fe}(OH)_3 + 3HCl$$

Solution becomes acidic due to hydrolysis. FeCl<sub>3</sub> sublimes at 300°C.

(ii) 
$$FeCl_3 + 3NH_4SCN \longrightarrow Fe(CNS)_3 + 3NH_4Cl$$
(B) Blood red

$$4\text{FeCl}_3 + 3\text{K}_4[\text{Fe}(\text{CN})_6] \longrightarrow \text{Fe}_4[\text{Fe}(\text{CN})_6]_3 + 12\text{KCl}_6(C)$$
 Prussian blue

(iii) 
$$4\text{FeCl}_3 + 9\text{H}_2\text{SO}_4 + 3\text{K}_2\text{Cr}_2\text{O}_7 \longrightarrow 6\text{CrO}_2\text{Cl}_2 + 2\text{Fe}_2(\text{SO}_4)_3 + 3\text{K}_2\text{SO}_4 + 9\text{H}_2\text{O}_4$$

(D)

Chromyl chloride

(iv) 
$$CrO_2Cl_2 + 4NaOH \longrightarrow 2NaCl + Na_2CrO_4 + 2H_2O$$
  
 $Na_2CrO_4 + (CH_3COO)_2Pb \longrightarrow PbCrO_4 + 2CH_3COONa$   
(E) Yellow ppt.

**Problem 14.** (i) A powdered substance (A) on treatment with fusion mixture gives a green coloured compound (B).

- (ii) The solution of (B) in boiling water on acidification with dilute  $H_2SO_4$  gives a pink coloured compound (C).
- (iii) The aqueous solution of (A) on treatment with excess of NaOH and bromine water gives a compound (D).
- (iv) A solution of (D) in conc.  $HNO_3$  on treatment with lead peroxide at boiling temperature produced a compound (E) which was of the same colour as that of (C).
- (v) A solution of (A) in dilute HCl on treatment with a solution of barium chloride gave a white precipitate of compound (F) which was insoluble in conc. HNO<sub>3</sub> and conc. HCl

Identify (A) to (F) and give balanced chemical equations for the reactions at steps (i) to (v). [Roorkee 2001]

#### Solution:

The compound (A) is a sulphate as its solution in dilute HCl on treatment with barium chloride solution gives a white precipitate of barium sulphate (F) which is insoluble in conc. HNO<sub>3</sub> and conc. HCl.

Solution of (A) in dilute 
$$HCl + BaCl_2 \longrightarrow BaSO_4$$
 (White ppt.)

(F)

Insoluble in conc.  $HNO_3$  and conc.  $HCl$ 

From reactions (i) and (ii), it is clear that the compound (A) is manganese sulphate.

(i) MnSO<sub>4</sub> + 
$$2Na_2CO_3 + 2KNO_3$$
  $\longrightarrow Na_2MnO_4$ 
(B)
Green coloured compound

+  $2KNO_2 + Na_2SO_4 + 2CO_2$ 
(ii)  $3Na_2MnO_4 + 2H_2SO_4 \longrightarrow 2NaMnO_4 + 2Na_2SO_4$ 
(B)
(C)
Pink coloured compound

+  $MnO_2 + 2H_2O_4$ 
(iii)  $MnSO_4 + 4NaOH + Br_2 \longrightarrow MnO_2 + Na_2SO_4$ 
(D)
+  $2NaBr + 2H_2O_4$ 
(iv)  $2MnO_2 + 10HNO_3 + 5PbO_2 \longrightarrow 2HMnO_4$ 

solution  

$$+ 5Pb(NO_3)_2 + 4H_2O + O_2$$
  
(v) MnSO<sub>4</sub> + BaCl<sub>2</sub>  $\longrightarrow$  BaSO<sub>4</sub> + MnCl<sub>2</sub>  
(F)

White ppt.

Pink coloured

**Problem 15.** A white substance (A) reacts with dilute  $H_2SO_4$  to produce a colourless gas (B) and a colourless

solution (C). The reaction between (B) and acidified  $K_2Cr_2O_7$  solution produces a green solution and a slightly coloured precipitate (D). The substance (D) burns in air to produce a gas (E) which reacts with (B) to yield (D) and a colourless liquid. Anhydrous copper sulphate is turned blue on addition of this colourless liquid. Addition of aqueous NH<sub>3</sub> or NaOH to (C) produces first a precipitate, which dissolves in the excess of respective reagent to produce a clear solution in each case. Identify (A), (B), (C), (D) and (E) write the equations of the reactions involved.

#### Solution:

The white substance (A) is ZnS.

 $S + O_2 \longrightarrow SO_2$ 

$$SO_2 + 2H_2S \longrightarrow 3S + 2H_2O$$

$$(E) \quad (B) \quad (D) \quad Colourless \ liquid$$

$$CuSO_4 + 5H_2O \longrightarrow CuSO_4 \cdot 5H_2O$$

$$White \quad Blue$$

$$(Anhydrous)$$

$$ZnSO_4 + 2NaOH \longrightarrow Zn(OH)_2 + Na_2SO_4$$

$$(C) \quad White \quad Fpt.$$

$$Zn(OH)_2 + 2NaOH \longrightarrow Na_2ZnO_2 + 2H_2O$$
Soluble in water

$$ZnSO_4 + 2NH_4OH \longrightarrow Zn(OH)_2 + (NH_4)_2SO_4$$

$$Zn(OH)_2 + (NH_4)_2SO_4 + 2NH_4OH \rightarrow [Zn(NH_3)_4]SO_4 + 4H_2O$$
Soluble complex (Clear solution)

**Problem 16.** When a crystalline compound 'X' is heated with  $K_2Cr_2O_7$  and concentrated  $H_2SO_4$ , a reddish brown gas 'A' is evolved. On passing 'A' into caustic soda, an yellow coloured solution of 'B' is obtained. Neutralizing the solution of 'B' with acetic acid and on subsequent addition of lead acetate, an yellow precipitate of 'C' is obtained. When 'X' is heated with NaOH, a colourless gas is evolved and on passing this gas into  $K_2HgI_4$  solution, a reddish brown precipitate 'D' is formed. Identify 'A', 'B', 'C', 'D' and 'X'. Write the equation of reactions involved.

#### **Solution:**

The given information in the question infer that compound 'X' will be NH<sub>4</sub>Cl.

$$K_2Cr_2O_7 + 2H_2SO_4 \longrightarrow 2KHSO_4 + 2CrO_3 + H_2O$$
  
 $NH_4Cl + H_2SO_4 \longrightarrow NH_4HSO_4 + HCl$ 

$$CrO_{3} + 2HCl \longrightarrow CrO_{2}Cl_{2} + H_{2}O$$

$$(A)$$

$$Reddish brown gas$$

$$CrO_{2}Cl_{2} + 4NaOH \longrightarrow Na_{2}CrO_{4} + 2NaCl + 2H_{2}O$$

$$(B)$$

$$Yellow coloured solution$$

$$Na_{2}CrO_{4} + (CH_{3}COO)_{2}Pb \xrightarrow{CH_{3}COOH}$$

$$PbCrO_{4} + 2CH_{3}COONa$$

$$(C)$$

$$(Yellow precipitate)$$

$$NH_4Cl + NaOH \longrightarrow NaCl + NH_3 + H_2O$$
Colourless gas

 $NH_2$ 
 $NH_3 + 2K_2HgI_4 + H_2O \longrightarrow Hg \longrightarrow Hg$ 
 $Hg \longrightarrow O$ 
 $Hg$ 

(Brown precipitate)

### PROBLEMS - • • • -

#### ■ Subjective Type Questions

- 1. What do you mean by inorganic mixture analysis and what do you do in it?
- 2. What are acidic and basic radicals? Or What are anions and cations?
- 3. Name the acid radicals detected with dilute H<sub>2</sub>SO<sub>4</sub>.
- 4. Name the acid radicals detected with concentrated H<sub>2</sub>SO<sub>4</sub>.
- 5. What is sodium carbonate extract? What is its utility in qualitative analysis?
- **6.** How will you test carbonate in a mixture? Can you test carbonate in presence of sulphite?
- 7. Is there any gas other than  $CO_2$  which turns lime water milky?
- **8.** How will you test sulphide in a mixture?
- **9.** What is chromyl chloride test? Explain it with reactions.
- 10. Name the brown gas evolved in the test of nitrate ion. How is this ion confirmed?
- 11. How will you detect bromide or iodide by chloroform layer test?
- 12. How will you detect oxalate in a mixture?
- 13. What is ring test? Explain it.
- 14. Name the acidic radicals that are detected when concentrated H<sub>2</sub>SO<sub>4</sub> is used alongwith:
  - (a) Copper turnings (b) Potassium dichromate (c) Ethyl alcohol.
- **15.** How will you test phost hate in a mixture? Is there any other radical which corresponds to this test?
- **16.** Why is original solution prepared for the identification of basic radicals? Why are HNO<sub>3</sub> and H<sub>2</sub>SO<sub>4</sub> generally not used for the preparation of an original solution?
- 17. What is a group reagent? Name the group reagents for second, third and fourth groups of mixture analysis.
- 18. Name the three chlorides which are insoluble in dilute HCl. Name one chloride, which is soluble in hot water but insoluble in cold water.
- 19. Sometimes, a white precipitate is obtained even in the absence of members of 1st group on the addition of HCl. Explain it.
- 20. Why does Hg<sub>2</sub>Cl<sub>2</sub> turn black on the addition of NH<sub>4</sub>OH?
- 21. State how the following substances may be dissolved? PbSO<sub>4</sub>; AgCl; BaSO<sub>4</sub>; HgS.

- 22. Give examples and explain with equations:
  - (a) Two colourless solutions give a black precipitate on mixing.

(Iodide of Millon's base)

- (b) Two colourless solutions give a red precipitate on mixing, soluble in excess of one of them.
- (c) Two colourless solutions give a white precipitate on mixing, soluble in ammonium hydroxide.
- (d) Two colourless solutions give a yellow precipitate on mixing.
- 23. Why are the members of IV group not precipitated in II group although H<sub>2</sub>S is group reagent in both?
- 24. What is yellow ammonium sulphide? Why is yellow ammonium sulphide and not ordinary ammonium sulphide used for the separation of IIA and IIB sub-groups?
- 25. For the analysis of basic radicals of group II, H<sub>2</sub>S is passed in acidic medium, while for the basic radicals of group IV, in alkaline medium, why so?
- **26.** Explain, while performing qualitative analysis of basic radicals of third group, why ammonium chloride is added in excess before adding ammonium hydroxide?
- 27. How is copper tested? What is the chocolate precipitate obtained in the test of copper?
- 28. Name the two sulphides which are yellow in colour. How will you test the basic radicals present in them?
- 29. What happens when?
  - (a) Copper sulphate is treated with excess of NH<sub>4</sub>OH.
  - (b) Bismuth chloride is treated with sodium stannite solution in presence of NaOH.
  - (c) Stannous chloride is treated with mercuric chloride.
  - (d) Excess of water is added to concentrated solution of antimony chloride.
- **30.** (a) What is the function of concentrated HNO<sub>3</sub> in third group?
  - (b) Will you add HNO<sub>3</sub> in third group even if iron is given in ferric state in the mixture?
  - (c) Can you use NaCl and NaOH instead of NH<sub>4</sub>Cl and NH<sub>4</sub>OH in third group?
- 31. (a) How will you test for iron?
  - (b) What is the yellow precipitate obtained in the test of chromium?
  - (c) Which hydroxide dissolves in NaOH? Give equation. (i) Fe(OH)<sub>3</sub> (ii) Cu(OH)<sub>3</sub> (iii) Al(OH)<sub>3</sub>.

- **32.** What is the colour of nickel sulphide? How is nickel tested by dimethyl glyoxime?
- 33. What is the group reagent of V group? Why is it necessary to test for V group radicals in the order of Ba<sup>2+</sup>, Sr<sup>2+</sup> and Ca<sup>2+</sup> only?
- **34.** What is the white precipitate obtained in the test of magnesium?
- 35. How will you test zinc ion and mercuric ion in the laboratory?
- **36.** Give the chemistry of flame test. What colour is obtained in the test of calcium and barium salts?
- **37.** How is borax bead test performed? Give the chemistry of this test.
- 38. An aqueous solution of salt (A) gives a white precipitate (B) with NaCl solution. The filtrate gives a black precipitate, (C) when H<sub>2</sub>S is passed into it. Compound (B) dissolves in hot water and the solution gives a yellow precipitate (D) on treatment with sodium iodide and cooling. The compound (A) does not give any gas with dilute HCl but liberates a reddish-brown gas on heating. Identify the compounds (A) to (D).

[Hint: Since the crystalline substance (B) dissolves in hot water and gives a yellow precipitate with NaI, it should be lead chloride (PbCl<sub>2</sub>) and the solution (A) consists a lead salt.

$$\begin{array}{c} \operatorname{PbCl_2} + \operatorname{2NaI} \longrightarrow & \operatorname{PbI_2} + \operatorname{2NaCl} \\ \text{(B)} & \operatorname{Yeilow} \\ \text{(D)} \end{array}$$

The compound (A) does not give any gas with dilute HCl but liberates a reddish-brown gas on heating, it should be lead nitrate, Pb(NO<sub>2</sub>)<sub>2</sub>.

$$\begin{array}{ccc} \text{Pb}(\text{NO}_3)_2 & \longrightarrow & \text{PbO} + 2\text{NO}_2 + \frac{1}{2}\text{O}_2 \\ & & \text{Reddish-brown gas} \end{array}$$

Lead chloride is sparingly soluble in water. When H<sub>2</sub>S is passed, it gives a black precipitate of lead sulphide, PbS.

$$PbCl_2 + H_2S \longrightarrow PbS + 2HCl$$
Black ppt.
(C)

Thus, (A) is lead nitrate,  $Pb(NO_3)_2$ ;

(B) is lead chloride, PbCl<sub>2</sub>;

(C) is lead sulphide, PbS;

and (D) is lead iodide, PbI<sub>2</sub>.]

39. A mixture of two salts was treated as follows:

- (i) The mixture was heated with manganese dioxide and concentrated H<sub>2</sub>SO<sub>4</sub>, when yellowish green gas was liberated.
- (ii) The mixture on heating with NaOH solution gave a gas which turned red litmus blue.
- (iii) Its solution in water gave blue precipitate with potassium ferricyanide and red colouration with NH<sub>4</sub>CNS.
- (iv) The mixture was boiled with potassium hydroxide and the liberated gas was bubbled through an alkaline solution of K<sub>2</sub>HgI<sub>4</sub> to give brown precipitate.

Identify the two salts. Give ionic reactions involved in the tests (i), (ii) and (iii). [LI.T. 1987]

[**Hint**: Tests (ii) and (iv) show the presence of ammonium radical.

Test (i) shows the presence of Cl<sup>-</sup> ion and test (iii) shows the presence of Fe<sup>2+</sup> and Fe<sup>3+</sup> ion.

$$2Cl^- + MnO_2 + H_2SO_4 + 2H^+ \longrightarrow MnSO_4 + 2H_2O + Cl_2$$
 (Yellowish green) 
$$NH_4^+ + OH^- \longrightarrow NH_3 + H_2O$$

NH<sub>3</sub> turns red litmus blue  

$$3Fe^{2^+} + 2[Fe(CN)_6]^{3^-} \longrightarrow Fe_3[Fe(CN)_6]_2$$
(Blue ppt.)  
 $Fe^{3^+} + 3CNS^- \longrightarrow Fe(CNS)_3$ 
(Blood red colour)

Thus, the mixture consists FeCl<sub>2</sub> and NH<sub>4</sub>Cl. Some of the FeCl<sub>2</sub> has undergone oxidation into FeCl<sub>3</sub> with atmospheric oxygen.]

- 40. Identify the unknown species and complete the following:
  - (i)  $(A) + BaCl_2 \longrightarrow White precipitate$
  - (ii) NaOH +  $(B) \longrightarrow NH_3$  gas
  - (iii) (C) + MnO<sub>2</sub> + H<sub>2</sub>SO<sub>4</sub>  $\longrightarrow$  Violet vapours
  - (iv) (D) +  $K_2Cr_2O_7$  +  $H_2SO_4$   $\longrightarrow$  Green coloured solution
  - $\begin{array}{ccc}
    (v) & (E) & \xrightarrow{\text{Heat}} & \text{Yellow compound} \\
    \hline
    & \text{Colourless} & \\
    & & \text{solid} & \\
    \end{array}$
- 41. (i) A black coloured compound (B) is formed on passing hydrogen sulphide through the solution of a compound (A) in NH<sub>4</sub>OH.
  - (ii) (B) on treatment with hydrochloric acid and KClO<sub>3</sub> gives (A).
  - (iii) (A) on treatment with potassium cyanide gives a buff coloured precipitate which dissolves in excess of this reagent forming a compound (C).
  - (iv) The compound (C) is changed into a compound (D) when its aqueous solution is boiled.
  - (v) The solution of (A) was treated with excess of sodium bicarbonate and then with bromine water. On cooling and shaking for sometime, a green colour of compound (E) is formed. No change is observed on heating.

Identify (A) to (E) and give chemical equations for the reactions at steps (i) to (v). [Roorkee 1996]

[Hint: The compound (A) is a cobalt salt (CoCl<sub>2</sub>).

(i) 
$$CoCl_2 + 2NH_4OH + H_2S \longrightarrow CoS + 2NH_4Cl + 2H_2O$$
(A) Black
(B)

(ii) CoS + 2HCl + O (from  $KClO_3$ )  $\longrightarrow CoCl_2 + H_2O + S$ 

(iii) 
$$CoCl_2 + 2KCN \longrightarrow Co(CN)_2 + 2KCl$$
Buff coloured
 $Co(CN)_2 + 4KCN \longrightarrow K_4[Co(CN)_6]$ 

- (iv)  $2K_4Fe(CN)_6 + H_2O + O$  (from air)  $\longrightarrow 2K_3Fe(CN)_6 + 2KOH$
- (v)  $CoCl_2 + 6NaHCO_3 \rightarrow Na_4[Co(CO_3)_3] + 2NaCl + 3CO_2 + 3H_2O$  $2Na_4[Co(CO_3)_3] + H_2O + O \longrightarrow 2Na_3[Co(CO_3)_3] + 2NaOH]$
- **42.** A colourless inorganic compound (A) is soluble in water, alcohols and amines. On strong heating (A) gives a brown gas (B) and a grey residue (C). On dissolution of (A) in NH<sub>3</sub>, a solution (D) is formed which reduces aldehydes to form silver mirror. FeSO<sub>4</sub> reduces solution of (A) in water. Aqueous solution of (A) also gives a brick red precipitate (E) with K<sub>2</sub>CrO<sub>4</sub> solution. Identify (A) to (E).
- **43.** A colourless solid (A) on hydrolysis produces a heavy white precipitate (B). Solid (A) gives a clear solution in conc. HCl; however, when added to large amount of water, it again gives precipitate of (B). When H<sub>2</sub>S is passed through a suspension

of (A) or (B), a brown black precipitate of (C) is obtained. Compound (A) liberates a gas (D) on treating with  $H_2SO_4$ . The gas (D) is water soluble and gives white precipitate (E) with solution of mercurous salt but not with mercuric salt. Identify (A) to (E). Also report (A), (B) and (C) if (C) is orange precipitate.

- 44. An inorganic compound (A) in its aqueous solution produced a white ppt. with NaOH, which gets dissolved in excess of NaOH. The aqueous solution of (A) also produced white ppt. with NH<sub>4</sub>OH which also dissolved in excess of NH<sub>4</sub>OH. Also its aqueous solution produced light yellow ppt. with AgNO<sub>3</sub> solution, soluble in dil. HNO<sub>3</sub>. Identify (A).
- 45. When a green solid (A) is fused with sodium carbonate in open air, a coloured salt (B) is formed. A solution of pure (B) gives a coloured precipitate with solutions of lead and barium salts. On extracting (B) with water and adding sulphuric acid, a further colour change takes place and crystals of (C) are obtained on evaporation. When warmed with alcohol, an acidified solution of (C) emits a characteristic smell and on evaporation and cooling, deposits dark violet crystals (D). On warming (C) with ammonium sulphate a colourless gas is produced and (A) is reformed. Identify (A), (B), (C) and (D) and explain the reactions involved.
- 46. There are two metal carbonates (A) and (B), which are insoluble in water but soluble in acetic acid with the evolution of CO<sub>2</sub>. When potassium chromate is added to their solution, (A) gives a yellow precipitate which gives pale green colouration in flame test. The precipitate is filtered out. The filtrate is treated with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, white ppt. is formed which gives crimson red colour in flame test. Identify (A) and (B) and also give equation for the reaction involved.
- 47. A colourless solid (A) on heating gives a white solid (B) and a colourless gas (C). (B) gives a reddish brown gas on treatment with dil. acids. When (B) is heated with solid NH<sub>4</sub>Cl, a colourless gas (D) and a residue (E) are obtained. When (A) is heated with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> a colourless gas (F) is obtained alongwith a white residue (G). Both (E) and (G) imparts yellow colour to flame. The gas (C) reacts with Mg to give white powder. The gas (D) is heated with calcium and the product on hydrolysis gives NH<sub>3</sub>. Identify (A) to (G).
- **48.** A white compound (A) on red heating decomposes to give a residue (B) and two gases (C) and (D). The gas (C) burns with a blue flame. The gas (D) turns lime water milky. The residue (B) on dissolving in water gives heat and solution is alkaline to litmus. The compound (A) imparts brick-red colour to flame. Identify (A) to (D).
- 49. A hydrated metallic salt (A), light green in colour, on careful heating gives a white anhydrous residue (B). (B) is soluble in water and its aqueous solution reacts with NO to give a dark brown compound (C). (B) gives a brown residue (D) and a mixture of two gases (E) and (F). The gases when passed through an acidified KMnO<sub>4</sub> solution discharges the pink colour and when passed through acidified BaCl<sub>2</sub> solution gave a white precipitate. Identify (A), (B), (C), (D), (E) and (F). [M.L.N.R. 1996]
- **50.** A salt is coloured. The anion with barium chloride gives white precipitate insoluble in conc. HNO<sub>3</sub>. When the solution

of this salt is treated with HCl, no precipitate is formed. When H<sub>2</sub>S is passed, no precipitate is formed. When NH<sub>4</sub>Cl and NH<sub>4</sub>OH are added, no precipitate is formed. H<sub>2</sub>S is passed when black precipitate is formed. The precipitate is dissolved in aqua-regia and dimethylglyoxime solution is added in ammonical solution when red precipitate is formed. Find the salt.

- **51.** An aqueous solution of salt gave the following reactions:
  - (i) With barium chloride solution, white precipitate insoluble in HCl is obtained.
  - (ii) Addition of excess KI gives a brown precipitate which turns white on addition of excess of hypo.
  - (iii) With potassium ferrocyanide solution, chocolate coloured precipitate is formed. Identify the salt.
- **52.** (i) The solution of salt (A) in dilute HCl gives a dirty yellow precipitate on passing H<sub>2</sub>S gas. The precipitate dissolves in yellow ammonium sulphide.
  - (ii) The salt (A) gives chromyl chloride test.
  - (iii) (A) first forms a white precipitate with NaOH which dissolves in excess of NaOH forming a compound (B).
  - (iv) The alkaline solution of (B) when added to bismuth chloride gives a black precipitate (C).
  - (v) (A) reduces HgCl<sub>2</sub> in solution to a white precipitate (D) which changes to grey. Identify (A), (B), (C) and (D). Give reactions at steps (i) to (v).

[Hint: The steps (i) and (ii) indicate that (A) is SnCl<sub>2</sub>.

(i) 
$$\begin{array}{ccc} SnCl_2 + H_2S & \longrightarrow & SnS + 2HCl \\ (A) & & Dirty & yellow \\ SnS + (NH_4)_2S_2 & \longrightarrow & SnS_2 + (NH_4)_2S \\ SnS_2 + (NH_4)_2S & \longrightarrow & (NH_4)_2SnS_3 \\ & & Soluble \end{array}$$

(iii) 
$$SnCl_2 + 2NaOH \longrightarrow_{\epsilon} Sn(OH)_2 + 2NaCl$$
  
White ppt.  $Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2$  (Sodium stannite)

(B)
Soluble

(iv) 
$$3\text{Na}_2\text{SnO}_2 + 6\text{NaOH} + 2\text{BiCl}_3 \longrightarrow 2\text{Bi} + 3\text{Na}_2\text{SnO}_3$$
(B)
(C)
Black ppt.
+  $6\text{NaCl} + 3\text{H}_2\text{O}$ 

(v) 
$$\operatorname{SnCl}_2 + 2\operatorname{HgCl}_2 \longrightarrow \operatorname{Hg}_2\operatorname{Cl}_2 + \operatorname{SnCl}_4$$

(D)

White ppt.

(Mercurous chloride)

 $\operatorname{Hg}_2\operatorname{Cl}_2 + \operatorname{SnCl}_2 \longrightarrow 2\operatorname{Hg} + \operatorname{SnCl}_4$ 

Grey

**53.** Identify the unknown species and complete the following equations:

(i) 
$$Na_2B_4O_7 \cdot 10H_2O + conc. H_2SO_4 \xrightarrow{\text{Heat}} (A)$$
  
 $\xrightarrow{(B)} (C_2H_5)_3BO_3$   
(ii)  $Na_3PO_4 + (NH_4)_2MoO_4 + HNO_3 \longrightarrow (C)$ 

Yellow ppt.

(iii) 
$$\text{NaF} + \text{H}_2 \text{SO}_4 + \text{SiO}_2 \longrightarrow (D)$$
 
$$(D) + \text{H}_2 \text{O} \longrightarrow (E)$$
 White (Silicic acid)

(iv) 
$$K_2Cr_2O_7 + KCl + conc. H_2SO_4 \longrightarrow Reddish$$
  
brown vapours (F)

$$(F)$$
 + NaOH  $\longrightarrow$  Yellow solution  $(G)$ 

$$(G) + (CH_3COO)_2 Pb \longrightarrow Yellow ppt. (H)$$

#### **54.** Identify the gas (X):

- (i) (X) is a colourless with pungent smell.
- (ii) (X) turns lime water milky.
- (iii) (X) turns acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution green.
- (iv) (X) decolourises acidified KMnO<sub>4</sub> solution.
- (v) (X) gives white turbidity when  $H_2S$  is passed through it aqueous solution.
- (vi) A white precipitate insoluble in conc. HNO<sub>3</sub> is formed when the aqueous solution of (X) in NaOH is treated with barium chloride and bromine water.

[Hint: (i) (X) is SO<sub>2</sub>. It is colourless and pungent. Rest of properties are observed with SO<sub>2</sub>.

(ii) 
$$Ca(OH)_2 + SO_2 \longrightarrow CaSO_3 + H_2O$$
Lime water Milky

(iii) 
$$K_2Cr_2O_7 + H_2SO_4 + 3SO_2 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O_{Green}$$

(iv) 
$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$
  
 $[SO_2 + O + H_2O \longrightarrow H_2SO_4] \times 5$ 

(vi) 
$$SO_2 + 2NaOH \longrightarrow Na_2SO_3 + H_2O$$
  
 $Na_2SO_3 + BaCl_2 \longrightarrow BaSO_3 + 2NaCl$   
 $Br_2 + H_2O \longrightarrow 2HBr + [O]$   
 $BaSO_3 + [O] \longrightarrow BaSO_4$   
White ppt.

(Insoluble in conc. HNO<sub>3</sub>)]

55. (A)  $\xrightarrow{\text{KOH}, \text{H}_2\text{O}_2}$  (B)  $\xrightarrow{\text{Cl}_2}$  (C)

Black substance Green Pink-violet

HCl HCl

Pale green gas  $\xrightarrow{\text{KI}}$  Violet vapours of iodine

(C) is a volumetric reagent. It can be used for estimation of ferrous sulphate and oxalic acid in acidic medium without employing any indicator.

Identify (A), (B), (C) and (D). Give all reactions.

56. A colourless salt (A) gives a mixture of three gases (B), (C) and (D) along with water vapours. Gas (B) is basic, (C) is acidic while (D) is neutral in nature. Gas (B) is also evolved when (A) is heated with KOH and gives brown precipitate with Nessler's reagent. The gas (C) when passes through lime water, gives white turbidity. Magnesium burns in the atmosphere of gas (C). The gas (D) burns with blue flame and is formed when potassium ferrocyanide is heated with

conc.  $H_2SO_4$ . The solution of (A) in water forms a white precipitate (E) with calcium chloride solution. The precipitate (E) decolourises acidified KMnO<sub>4</sub> solution.

Identify (A) to (E) and explain reactions.

- 57. (i) A black coloured compound (B) is formed on passing hydrogen sulphide through the solution of (A) in NH<sub>4</sub>OH.
  - (ii) (B) on treatment with aqua-regia gives (A).
  - (iii) The solution of (A) is treated with excess of sodium bicarbonate and then with NaOH and bromine water. No apple green colour is observed. The solution is heated, when a black precipitate (C) is obtained.
  - (iv) (A) on treatment with potassium cyanide gives a buff coloured precipitate which dissolves in excess of this reagent forming a compound (D).

Identify (A) to (D) and give chemical equations for the reactions at steps (i) to (iv).

- **58.** Explain with proper reasoning:
  - (i) The aqueous solution of ferric chloride cannot be stored. It is always acidified with hydrochloric acid.

[Hint: Ferric chloride is a salt of weak base and a strong acid. Its hydrolysis occurs readily with the formation of Fe(OH)<sub>3</sub> ppt.

$$FeCl_3 + 3H_2O \rightleftharpoons Fe(OH)_3 + 3HCl$$
  
The addition of HCl prevents hydrolysis.]

(ii) The aqueous solution of FeCl<sub>3</sub> possesses yellow colour, but the colour becomes green on passing H<sub>2</sub>S gas.

[Hint: Reduction of FeCl<sub>3</sub> occurs into ferrous chloride which gives green coloured solution.

$$\begin{array}{ccc} 2\text{FeCl}_3 + \text{H}_2\text{S} & \longrightarrow & 2\text{FeCl}_2 + 2\text{HCl} + \text{S}] \\ \text{Yellow} & & \text{Green} \end{array}$$

(iii) The aqueous solution of K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is orange. On adding an alkali, it turns yellow.

[Hint: In presence of alkali, dichromate changes to chromate.

$$Cr_2O_7^{2-} + 2OH^- \longrightarrow 2CrO_4^{2-} + H_2O$$
Orange Yellow

(iv) In the test of oxalate, the evolved gas burns with blue flame only initially.

[Hint: CO is evolved along with CO<sub>2</sub>.CO burns with blue flame while CO<sub>2</sub> prevents its burning.

$$H_2C_2O_4 \xrightarrow{\text{Heat}} H_2O + CO + CO_2$$

CO diffuses faster than CO<sub>2</sub>. Once CO burns with blue flame, it is put off by CO<sub>2</sub> which diffuses later.]

(v) Why yellow ammonium sulphide is used in group (II) sulphides separation?

[Hint: Yellow ammonium sulphide possesses excess of free sulphur. It combines with stannous sulphide (SnS) to convert it to stannic sulphide (SnS<sub>2</sub>) which forms soluble complex with (NH<sub>4</sub>)<sub>2</sub>S.

$$SnS + S \longrightarrow SnS_2$$

$$SnS_2 + (NH_4)_2S \longrightarrow (NH_4)_2SnS_3$$

**Note:** In case, tin compound is not present in the mixture, ordinary ammonium sulphide can be used instead of yellow ammonium sulphide.

(vi) Why zinc sulphide is not precipitated when H<sub>2</sub>S is passed through ZnCl<sub>2</sub> solution?

[Hint: The reaction of ZnCl<sub>2</sub> and H<sub>2</sub>S produces HCl which dissolves ZnS.

$$ZnCl_2 + H_2S \longrightarrow ZnS + 2HCl$$

(vii) CaSO<sub>4</sub> is insoluble but is not precipitated when excess of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> is added to CaCl<sub>2</sub>.

[Hint : The precipitate of  $CaSO_4$  dissolves in  $(NH_4)_2SO_4$  forming a complex (double sulphate).

 $CaSO_4 + (NH_4)_2SO_4 \longrightarrow (NH_4)_2Ca(SO_4)_2$ Soluble

(viii) Why (NH<sub>4</sub>Cl+NH<sub>4</sub>OH) and not [(NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>+NH<sub>4</sub>OH] is used in group (III) analysis?

[Hint: The presence of sulphate ions brings precipitation of various basic ions such as Ca<sup>2+</sup>, Ba<sup>2+</sup>, Sr<sup>2+</sup>, etc.]

(ix) Why is it necessary to add few drops of conc. HNO<sub>3</sub> to the filtrate of group (II) before the use of NH<sub>4</sub>Cl + NH<sub>4</sub>OH?

[Hint: The addition of few drops of conc. HNO<sub>3</sub> serves two purposes.

- (a) It precipitates the dissolved H<sub>2</sub>S.
- (b) It converts ferrous ion into ferric ion if iron is present.]
- (x) Why NaOH cannot be used to separate Al(OH)<sub>3</sub> and Zn(OH)<sub>2</sub>?

[Hint: Both the hydroxides dissolve in NaOH.

Al(OH)<sub>3</sub> + NaOH → NaAlO<sub>2</sub> + 2H<sub>2</sub>O Soluble

 $Zn(OH)_2 + 2NaOH \longrightarrow Na_2ZnO_2 + 2H_2O$ Soluble

### Answers

#### **Answers:** Subjective Type Questions

- 18. PbCl<sub>2</sub>; AgCl; Hg<sub>2</sub>Cl<sub>2</sub>, PbCl<sub>2</sub> is soluble in hot water.
- 21. PbSO<sub>4</sub> is soluble in ammonium acetate (3%).

PbSO<sub>4</sub> + 2CH<sub>3</sub>COONH<sub>4</sub>  $\longrightarrow$  Pb(CH<sub>3</sub>COO)<sub>2</sub> + (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> AgCl is soluble in ammonium hydroxide.

 $AgCl + 2NH_4OH \longrightarrow Ag(NH_3)_2Cl + 2H_2O$ 

BaSO<sub>4</sub> is boiled with concentrated solution of sodium carbonate. The barium carbonate is then dissolved in dil. acetic acid.

 $BaSO_4 + Na_2CO_3 \longrightarrow BaCO_3 + Na_2SO_4$ 

 $BaCO_3 + 2CH_3COOH \longrightarrow (CH_3COO)_2Ba + CO_2 + H_2O$ HgS is dissolved in aqua-regia.

 $3HgS + 2HNO_3 + 6HCl \longrightarrow 3HgCl_2 + 2NO + 3S + 4H_2O$ 

22. (a) Lead salt + sodium sulphide.

 $Pb(CH_3COO)_2 + Na_2S \longrightarrow PbS + 2CH_3COONa$ Black

 $\label{eq:HgCl2} \text{HgCl}_2 + 2\text{KI} \xrightarrow{} \text{HgI}_2 + 2\text{KCl} \\ \text{Red}$ 

 $HgI_2 + 2KI \longrightarrow K_2HgI_4$ Soluble

(c)  $AgNO_3 + NaCl \longrightarrow AgCl + NaNO_3$  White ppt.

 $\begin{array}{c} AgCl + 2NH_4OH \longrightarrow Ag(NH_3)_2Cl + 2H_2O \\ Soluble \end{array}$ 

 $\begin{array}{ccc} \text{(d)} & & Pb(\text{NO}_3)_2 \, + \, 2KI \longrightarrow PbI_2 \, + \, 2KNO_3 \\ & & \text{Yeliow ppt.} \end{array}$ 

- 28. CdS and As<sub>2</sub>S<sub>3</sub>.
- 29. (a)  $CuSO_4 + 2NH_4OH \longrightarrow Cu(OH)_2 + (NH_4)_2SO_4$

 $Cu(OH)_2 + (NH_4)_2SO_4 + 2NH_4OH \longrightarrow Cu(NH_3)_4SO_4 + 4H_2O$ (b)  $2BiCl_3 + 3Na_2SnO_2 + 6NaOH \longrightarrow 2Bi + 3Na_2SnO_3 + 6NaCl$ 

+ 3H<sub>2</sub>O

- (c)  $2\text{HgCl}_2 + \text{SnCl}_2 \longrightarrow \text{Hg}_2\text{Cl}_2 + \text{SnCl}_4$  $\text{Hg}_2\text{Cl}_2 + \text{SnCl}_2 \longrightarrow 2\text{Hg} + \text{SnCl}_4$
- (d)  $SbCl_3 + H_2O \longrightarrow SbOCl + 2HCl$
- 31. (c) Al(OH)<sub>3</sub> dissolves in NaOH.

  Al(OH)<sub>3</sub> + NaOH  $\longrightarrow$  NaAlO<sub>2</sub> + 2H<sub>2</sub>O

- 40. (i) sulphate, (ii) ammonium salt, (iii) iodide (iv) reducing agent such as sulphite, SO<sub>2</sub>, sulphide, H<sub>2</sub>S, nitrite, etc., (v) ZnO.
- **42.** (A) AgNO<sub>3</sub>; (B) NO<sub>2</sub>; (C) Ag; (D)  $[Ag(NH_3)_2]^+$ ; (E) Ag<sub>2</sub>CrO<sub>4</sub>
- 43. (A) BiCl<sub>3</sub>; (B) BiOCl; (C) Bi<sub>2</sub>S<sub>3</sub>; (D) HCl; (E) Hg<sub>2</sub>Cl<sub>2</sub>

- 57. (A) NiCl<sub>2</sub>; (B) NiS; (C) Ni<sub>2</sub>O<sub>3</sub>; (D) K<sub>2</sub>Ni(CN)<sub>4</sub>

### ILLUSTRATIONS OF OBJECTIVE QUESTIONS

- 1. A salt made of bivalent ions X and Y, each of which is capable of decolourising acidified KMnO<sub>4</sub> solution. The salt is likely
  - (a) stannic chloride
- (b) ferric sulphate
- (c) ferrous sulphate
- (d) ferrous oxalate

Ans. (d)

[Hint: Ferrous oxalate consists of Fe<sup>2+</sup> and C<sub>2</sub>O<sub>4</sub><sup>2-</sup> ions. Both act as reducing agents and decolourise acidified KMnO4

$$2MnO_4^- + 16H^+ + 10Fe^{2+} \longrightarrow 2Mn^{2+} + 10Fe^{3+} + 8H_2O$$
  
 $2MnO_4^- + 16H^+ + 5C_2O_4^{2-} \longrightarrow 2Mn^{2+} + \cdot 10CO_2 + 8H_2O]$ 

- 2. Which of the following salt will evolve sulphur dioxide gas along with formation of yellowish turbidity when treated with dilute H2SO4?
  - (a) Sodium sulphide
- (b) Sodium sulphite
- (c) Sodium thiosulphate
- (d) Sodium sulphate

Ans. (c)

[Hint: Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> is decomposed by dilute H<sub>2</sub>SO<sub>4</sub> giving free sulphur and evolving SO<sub>2</sub> gas.

$$Na_2S_2O_3 + H_2SO_4 \longrightarrow Na_2SO_4 + S + SO_2 + H_2O]$$
(Yellowish turbidity)

- 3. A colourless salt gives white precipitate with CaCl<sub>2</sub> solution. The salt also decolourises acidified MnO<sub>4</sub> with effervescence. On reaction with conc. H<sub>2</sub>SO<sub>4</sub>, the salt gives a colourless gaseous mixture containing:
  - (a)  $CO, CO_2$
- (b)  $CO_2$ ,  $SO_2$
- (c) CO<sub>2</sub>, H<sub>2</sub>S
- (d)  $CO, SO_2$

Ans. (a)

[Hint: The colourless salt is an oxalate which on reaction with conc. H<sub>2</sub>SO<sub>4</sub> gives a gaseous mixture CO and CO<sub>2</sub>. The salt gives a white ppt. with CaCl2 solution and decolourises acidified KMnO<sub>4</sub> solution.

$$C_{2}O_{4}^{2-} + Ca^{2+} \longrightarrow CaC_{2}O_{4};$$

$$5C_{2}O_{4}^{2-} + 16H^{+} + 2MnO_{4}^{-} \longrightarrow 2Mn^{2+} + 10CO_{2} + 8H_{2}O;$$

$$C_{2}O_{4}^{2-} + 2H^{+} \longrightarrow CO + CO_{2} + H_{2}O]$$

- Aqueous solution of a salt + MgSO<sub>4</sub> solution  $\longrightarrow$  no ppt. Heating a white ppt. appears. The salt contains the acidic radical:
  - (a)  $CO_3^{2-}$

(c)  $SO_3^2$ 

(d)  $C_2O_4^2$ 

[Hint: Bicarbonate ion does not give ppt. with MgSO<sub>4</sub> in cold but on heating, a white ppt. appears.

$$Mg^{2+} + 2HCO_3^- \longrightarrow Mg(HCO_3)_2 \xrightarrow{Heat} MgCO_3 + CO_2 + H_2O$$
 ]

Soluble White ppt.

5. Which of the following is formed when CO<sub>2</sub> gas is passed through an aqueous solution of sodium chromate?

- (a) Cr(OH)<sub>3</sub> is precipitated
- (b) Yellow solution of Cr<sub>2</sub>(CO<sub>3</sub>)<sub>2</sub> is formed
- (c) Orange solution of Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is formed
- (d) No reaction

Ans. (c)

[Hint: CO2 makes the solution acidic. Under acidic conditions, Na<sub>2</sub>CrO<sub>4</sub> is converted into Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>.1

In the reactions,

$$K_2Cr_2O_7 + KCl + Conc. H_2SO_4 \xrightarrow{\text{Heat}} A \xrightarrow{\text{NaOH}} B.$$
 A is reddish brown gas soluble in NaOH forming B. A and B are:

- (a) CrO<sub>2</sub>Cl<sub>2</sub>, Na<sub>2</sub>CrO<sub>4</sub>
- (b) CrO<sub>2</sub>Cl<sub>2</sub>, Na<sub>2</sub>Cr<sub>2</sub>O<sub>4</sub>
- (c) CrO<sub>2</sub>Cl<sub>2</sub>, Na<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>
- (d) CrO<sub>2</sub>Cl, Na<sub>2</sub>CrO<sub>4</sub>

Ans. (a)

Ans. (a)
$$[\textbf{Hint}: K_2Cr_2O_7 + 4KCl + 6H_2SO_4 \longrightarrow \\ 6KHSO_4 + 2CrO_2Cl_2 + 3H_2O \\ \text{Reddish} \\ \text{brown gas} \\ (A)$$

$$CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow Na_2CrO_4 + 2NaCl + 2H_2O ] \longrightarrow \\ CrO_2Cl_2 + 4NaOH \longrightarrow \\ CrO_2Cl$$

- 7. As<sub>2</sub>S<sub>3</sub> dissolves in a solution of yellow ammonium sulphide to give:
  - (a)  $(NH_4)_2AsO_2$
- (b)  $(NH_4)_3AsS_3$
- (c)  $(NH_4)_3AsS_4$
- (d)  $(NH_4)_3AsS_5$

Ans. (c)

- [Hint:  $As_2S_3 + 2(NH_4)_2S_2 \longrightarrow As_2S_5 + 2(NH_4)_2S$  $As_2S_5 + 3(NH_4)_2S \longrightarrow 2(NH_4)_3AsS_4$
- 8. Which of the following sulphide is completely precipitated only when the acidic solution is made dilute?
  - (a) HgS

(b) PbS

(c) CuS

- (d) CdS
- Ans. (d)
- Which of the following compound on reaction with NaOH and Na<sub>2</sub>O<sub>2</sub> gives yellow colour?
  - (a) Cr(OH)<sub>3</sub>
- (b)  $Zn(OH)_2$
- (c) Al(OH)<sub>3</sub>
- (d) None of these

Ans. (a) [Hint:  $2Cr(OH)_3 + 3[O] + 4NaOH \longrightarrow 2Na_2CrO_4 + 5H_2O$ ] (From Na2O2)

- 10. In group V,  $(NH_4)_2CO_3$  is added to precipitate out carbonates. In place of (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub>, why Na<sub>2</sub>CO<sub>3</sub> cannot be used because:
  - (a) CaCO<sub>3</sub> is soluble in Na<sub>2</sub>CO<sub>3</sub>
  - (b) MgCO<sub>3</sub> will be precipitated
  - (c) Double carbonates are precipitated
  - (d) None of the above

Ans. (b)

### **OBJECTIVE QUESTIONS**

**Note:** Choose the correct answer out of given alternatives for each question.

I.	Which of the following gives a suffocating gas when treated	11.	Aqueous solution of A gives yellow precipitate with aque	
	with dilute HCl?	1	solution of K <sub>2</sub> CrO <sub>4</sub> . Which of the following series of cat	ions
	(a) carbonate $\Box$ (b) sulphite $\Box$	1	may be present in 'A':	
_	(c) sulphate $\Box$ (d) borate $\Box$		(a) $Pb^{2+}$ , $Ag^{+}$	
2.	The acidic solution of a salt produces blue colour with KI		(c) $Ag^+$ , $Cu^{2+}$	
	starch solution. The salt may be:	12.	Mercurous chloride turns black on treatment with ammon	iium
	(a) sulphite $\Box$ (b) bromide $\Box$		hydroxide. This is due to the formation of:	
	(c) nitrite $\Box$ (d) chloride $\Box$	l	(a) $Hg(NH_2)Cl$	
3.	Sulphite on treatment with dil. H <sub>2</sub> SO <sub>4</sub> liberates a gas which:		(c) Hg and HgNH <sub>2</sub> Cl $\Box$ (d) HgCl <sub>2</sub> ·NH <sub>4</sub> OH	
	(a) turns lead acetate paper black	13.	A light yellow precipitate is formed in the second grou	p of
-	(b) burns with blue flame		the qualitative analysis on passing H <sub>2</sub> S even when no rac	
	(c) smells like vinegar		of second group is present. This is due to the presence	
	(d) turns acidified $K_2Cr_2O_7$ paper green	1	in the mixture.	
4.	In the ring test for nitrates, the ring formed is due to:		(a) phosphate	
	(a) $FeSO_4 \cdot NO$ $\square$ (b) $FeSO_4 \cdot NO_2$ $\square$		(c) oxalate	
	(c) $Fe(NO_3)_3$ $\square$ (d) $Fe_2(SO_4)_3 \cdot NO$ $\square$	14.	An orange precipitate in the second group is given by	:
5.	Violet vapours are given out whenis treated with		(a) $Sb^{3+}$	
	conc. H <sub>2</sub> SO <sub>4</sub> .	)	(c) $Hg^{2+}$ $\Box$ (d) $As^{3+}$	<u> </u>
	(a) bromide $\Box$ (b) iodide $\Box$	15	A precipitate of which of the following would be obta	_
	(c) chloride $\Box$ (d) nitrate $\Box$	15.	when HCl is added to a solution of stannous sulphide (\$\frac{1}{2}\$)	
6.	Oxalate + MnO <sub>2</sub> + dil. $H_2SO_4 \longrightarrow Gas$ . The gas evolved is:	[	in yellow ammonium sulphide?	)IIO)

Identify the metal ion: [1.I.T. 2005]  (a) $Hg^{2+}$ $\Box$ (b) $Bi^{3+}$ $\Box$ (c) $Cu^{2+}$ $\Box$ (d) $Pb^{2+}$ $\Box$ When calomel reacts with $NH_4OH$ solution, the compound
	<ul> <li>(a) In Vth group, K<sub>2</sub>CrO<sub>4</sub> is used for the test of Ba<sup>2+</sup> □</li> <li>(b) Ammonium sulphate can be used in place of NH<sub>4</sub>Cl in IIIrd group □</li> </ul>		formed is: [B.C.E.C.E. (Medical) 2005] (a) $NH_2(Hg)Cl$ $\Box$ (b) $Hg_2Cl_2NH_3$ $\Box$ (c) $Hg(NH_3)_2Cl_2$ $\Box$ (d) $HgCl_2NH_3$ $\Box$
	(c) Lime water is used for the test of $CO_3^{2-}$ . $\Box$ (d) Ammonium thiocyanate can be used in the detection of $CO_3^{2+}$ and $CO_3^{2+}$ $\Box$	79.	The brown ring test for nitrates depends on:  (a) the reduction of nitrate to nitric oxide
69.	$Co^{2+}$ and $Fe^{3+}$ ions $\Box$ When $H_2S$ gas is passed in a metal sulphate solution in presence of NH <sub>4</sub> OH, a white precipitate is produced. The	,	(b) oxidation of nitric oxide to nitrogen dioxide (c) reduction of ferrous sulphate to iron (d) oxidising action of sulphuric acid  □
	metal is identified as: [C.P.M.T. 2003] (a) Zn $\square$ (b) Fe $\square$	80.	The formula of the compound which gives violet colour in Lassaigne's test for sulphur with sodium nitroprusside is:
	(c) Pb (d) Hg		[P.M.T. (Kerala) 2006]
70.	In the test for iodine, when $I_2$ is treated with sodium thiosulphate, $Na_2S_2O_3$ :		(a) $Na_4[Fe(CN)_6S]$ $\square$ (b) $Na_4[Fe(CN)_5NCS]$ $\square$ (c) $Na_4[Fe(CN)_5NOS]$ $\square$ (d) $Na_2[Fe(CN)_5NOS]$ $\square$
	$Na_2S_2O_3 + I_2 \longrightarrow NaI +$ [B.H.U. 2003]	81.	MgSO <sub>4</sub> on reaction with NH <sub>4</sub> OH and Na <sub>2</sub> HPO <sub>4</sub> forms a white
	(a) $Na_2S_4O_6$ $\square$ (b) $Na_2SO_4$ $\square$		crystalline precipitate. What is its formula? [I.I.T. 2006]
	(c) $Na_2S$ $\square$ (d) $Na_3ISO_4$ $\square$		(a) $Mg(NH_4)PO_4$ $\square$ (b) $Mg_3(PO_4)_2$ $\square$
71.	Which of the following sulphides is yellow in colour?		(c) $MgCl_2 \cdot MgSO_4$
/1.	[P.M.T.(M.P.) 2005]	1	[Hint: $MgSO_4 + NH_4OH + Na_2HPO_4 \longrightarrow$
	(a) CuS		$Mg(NH_4)PO_4 + Na_2SO_4 + H_2O$
	(c) $ZnS$ $\Box$ (d) $CoS$ $\Box$		(white ppt.)
72.	Brown ring in the test of $NO_3^-$ is formed due to the formation	82.	A solution when diluted with water and boiled, gives a white
1 2000	of: [P.M.T.(M.P.) 2005]		precipitate. On addition of excess of NH <sub>4</sub> Cl/NH <sub>4</sub> OH, the
	(a) FeSO <sub>4</sub> ·NO		volume of precipitate decreases leaving behind a white
	(c) $Fe_2(SO_4)_3$ NO $\Box$ (d) none of these $\Box$		gelatinous precipitate. Identify the precipitate which
72			dissolves in NH <sub>4</sub> OH/NH <sub>4</sub> Cl: [I.I.T. 2006]
73.			(a) $Zn(OH)_2$ $\Box$ (b) $Al(OH)_3$ $\Box$
	by $H_2S$ gas in the presence of $NH_3$ ? [Jamia 2004] (a) $Mn^{2+}$ $\square$ (b) $Ni^{2+}$ $\square$		(c) $Mg(OH)_2$ $\square$ (d) $Ca(OH)_2$ $\square$
	2.		$[Hint]: Zn^{2+} + 4NH_4OH \longrightarrow [Zn(NH_3)_4]^{2+} + 4H_2O]$
71		83.	A sodium salt of unknown anion when treated with MgCl <sub>2</sub>
74.			gives white precipitate only on boiling. The anion is:
	[P.M.T.(Punjab) 2005]		[I.I.T. 2004]
	(a) $Fe(OH)_3$		(a) $SO_4^{2-}$
75.	(c) $Al(OH)_3$		$\square$ (c) $CO_3^{2-}$ $\square$ (d) $NO_3^ \square$
13.	Nessler's reagent is: [P.M.T.(Raj.) 2005]		[Hint: $MgCl_2 + 2NaHCO_3 \longrightarrow Mg(HCO_3)_2 \xrightarrow{Boil} MgCO_3$ ]
	(a) NaHgCl <sub>4</sub> $\square$ (b) K <sub>2</sub> HgI <sub>4</sub> $\square$	0.4	Soluble ppt.
	(c) $Hg(NH_3)_2Cl$ $\Box$ (d) $K_2HgI_4 + KOH$ $\Box$	84.	Iron is precipitated as Fe(OH) <sub>3</sub> in the third group and not as
76.	If Fe <sup>3+</sup> and Cr <sup>3+</sup> both are present in group III of qualitative	,	Fe(OH) <sub>2</sub> because:
	analysis, then distinction can be made by:		(a) Fe(OH) <sub>2</sub> is light green ☐ (b) Fe(OH) <sub>3</sub> is reddish brown ☐
	[Jamia(Engg.) 2005]		(c) Fe(OH) <sub>2</sub> is partially soluble and is not completely
	(a) addition of NH <sub>4</sub> OH in presence of NH <sub>4</sub> Cl, when only		precipitated
	Fe(OH) <sub>3</sub> is precipitated		(d) Fe(OH) <sub>2</sub> is oxidant
	(b) addition of NH <sub>4</sub> OH in presence of NH <sub>4</sub> Cl, when Cr(OH) <sub>3</sub>	85	From the following information,
	and Fe(OH) <sub>3</sub> both are precipitated and on adding Br <sub>2</sub> water and NaOH, Cr(OH) <sub>3</sub> dissolves	05.	$X + H_2SO_4 \longrightarrow Y$ (a colourless and irritating gas)
			$Y + K_2Cr_2O_7 + H_2SO_4 \longrightarrow $ (Green coloured solution)
	(c) precipitates of Cr(OH) <sub>3</sub> and Fe(OH) <sub>3</sub> as obtained in (b) are treated with conc. HCl, when only Fe(OH) <sub>3</sub> dissolves	Ì	Identify the pair $X$ and $Y$ from the list given below:
	are treated with conc. HCI, when only Fe(OH)3 dissolves		(a) CI, HCl $\Box$ (b) $S^2$ , $H_2S$ $\Box$
	(d) (b) and (c) both are correct		2
	(a) (b) and (c) boat are edited:	1	(c) $CO_3^{2-}$ , $CO_2$

6		
	[Hint: $SO_3^{2-} + H_2SO_4 \longrightarrow SO_4^{2-} + SO_2 + H_2O$	94. The brown ring test for nitrates depends on:
	$K_2Cr_2O_7 + H_2SO_4 + 3SO_2 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O]$	[A.F.M.C. 2008]
	Green	(a) the reduction of nitrate to nitric oxide $\Box$
86.	$K_4$ Fe(CN) <sub>6</sub> is not used for the detection of:	(b) oxidation of nitric oxide to nitrogen dioxide $\Box$
	(a) $Zn^{2+}$ ions $\Box$ (b) $Cu^{2+}$ ions $\Box$	(c) reduction of ferrous sulphate to iron $\Box$
	(c) $Fe^{3+}$ ions $\Box$ (d) $Fe^{2+}$ ions $\Box$	(d) oxidising action of sulphuric acid $\Box$
07		95. $S^{2-}$ and $SO_3^{2-}$ can be distinguished by using:
87.	When H <sub>2</sub> S gas is passed through the HCl containing	[A.I.I.M.S. 2008]
	aqueous solution of CuCl <sub>2</sub> , HgCl <sub>2</sub> , BiCl <sub>3</sub> and CoCl <sub>2</sub> , it does	(a) $(CH_3COO)_2Pb$ $\Box$ (b) $Na_2[Fe(CN)_5NO]$ $\Box$
	not precipitate out: [A.I.I.M.S. 2007] (a) CuS	(c) both (a) and (b) $\Box$ (d) none of these $\Box$
	_ (-)8	96. In which of the following ammonia is not used?
00	( ) 2 3	[C.E.T. (Karnataka) 2009]
88.	A metal salt solution forms a yellow precipitate with sodium chromate solution and a white precipitate with sodium	(a) Nessler's reagent
	sulphate solution. However, it gives no precipitate with	(b) group reagent for analysis of IVth group basic radicals
	sodium chloride or iodide solution. The metal salt is:	
	(a) $Pb(NO_3)_2$ $\Box$ (b) $Ba(NO_3)_2$ $\Box$	(c) group reagent for analysis of IIIrd group basic radicals
	(a) $FO(NO_3)_2$	
89.	A certain light green salt gives ammonia on heating with	(d) Tollens reagent
67.	NaOH solution. Its aqueous solution gives white precipitate	97. The incorrect statement in respect of chromyl chloride test
	with barium chloride solution. Aqueous solution also shows	is: [C.E.T. (Karnataka) 2009]
	the presence of Fe(II) ion. The salt is likely to be:	(a) formation of lead chromate
	(a) ferrous sulphate $\Box$ (b) Mohr's salt $\Box$	(b) formation of chromyl chloride
	(c) ferric alum	(c) liberation of chloride
90.	A solution of a metal ion when treated with KI gives a red	(d) formation of red vapours
	precipitate which dissolves in excess of KI to give a	98. Out of Cu <sup>2+</sup> , Ni <sup>2+</sup> , Co <sup>2+</sup> and Mn <sup>2+</sup> those dissolve in dil. HCl
	colourless solution. Moreover, the solution of metal ion on	only one gives a precipitate when H <sub>2</sub> S is passed. Identify
	treatment with a solution of cobalt(II)thiocyanate gives rise	the corresponding one: [J.E.E. (Orissa) 2009]
	to deep blue crystalline precipitate. The metal ion is:	(a) $Ni^{2+}$ $\Box$ (b) $Cu^{2+}$ $\Box$
	[L.I.T. 2007]	(c) $\operatorname{Co}^{2+}$ $\square$ (d) $\operatorname{Mn}^{2+}$ $\square$
	(a) $Pb^{2+}$ $\Box$ (b) $Hg^{2+}$ $\Box$	99. A white crystalline salt A reacts with dilute HCl to liberate a
	(a) $Pb^{2+}$ $\square$ (b) $Hg^{2+}$ $\square$ (c) $Cu^{2+}$ $\square$ (d) $Co^{2+}$ $\square$	suffocating gas B and also forms a yellow precipitate. The
		gas B turns potassium dichromate acidified with dilute H <sub>2</sub> SO <sub>4</sub>
	[Hint: $Hg^{2+} + 2I^{-} \longrightarrow HgI_{2}$ Red upt.	to a green coloured solution C. A, B and C are respectively:
	11	[C.E.T. (Karnataka) 2010]
	$HgI_2 + 2KI \longrightarrow K_2HgI_4$ Soluble	(a) $Na_2SO_3$ , $SO_2$ , $Cr_2(SO_4)_3$
		(b) $Na_2S_2O_3$ , $SO_2$ , $Cr_2(SO_4)_3$
	$Hg^{2+} + Co(SCN)_2 \longrightarrow Co[Hg(SCN)_4]$ ] Deep blue ppt.	(c) $Na_2S$ , $SO_2$ , $Cr_2(SO_4)_3$
<b>Q</b> 1	In the brown ring test, the brown colour of the ring is due	(d) $Na_2SO_4$ , $SO_2$ , $Cr_2(SO_4)_3$
<i>)</i> 1.	to: [C.E.T. (Karnataka) 2008]	[ <b>Hint</b> : $Na_2S_2O_3 + 2HCl \longrightarrow 2NaCl + SO_2 + S + H_2O$
	(a) a mixture of NO and NO <sub>2</sub> $\Box$	(A) (B) Yellow ppt.
	(b) nitrosoferrous sulphate	
	(c) ferrous nitrate	$ K_2 \operatorname{Cr}_2 \operatorname{O}_7 + H_2 \operatorname{SO}_4 + \operatorname{SO}_2 \longrightarrow \operatorname{Cr}_2 (\operatorname{SO}_4)_3 ] $ (C)
	(d) ferric nitrate	
92.	When KI is added to acidified solution of sodium nitrite:	$100. A + CH3COOH \longrightarrow B + CO2 + H2O$ Soluble
	[J.E.E. (W.B.) 2008]	
	(a) NO gas is liberated and I <sub>2</sub> is set free	$B + (NH_4)_2 C_2 O_4 \longrightarrow White ppt.$
	(b) $N_2$ gas is liberated and HI is produced	A and B may contain:
	(c) $N_2O$ gas is liberated and $I_2$ is set free $\square$	(a) $Ni^{2+}$
	(d) $N_2$ gas is liberated and HOI is produced	
	[Hint: $2I^- + 4H^+ + 2NO_2^- \longrightarrow 2NO + I_2 + 2H_2O$ ]	[Hint: $CaCO_3 + 2CH_3COOH \longrightarrow (CH_3COO)_2Ca + CO_2 + H_2O$
93.		(A) (B)
	[J.E.E. (W.B.) 2008]	$Ca(CH_3COO)_2 + (NH_4)_2C_2O_4 \longrightarrow CaC_2O_4 + 2CH_3COONH_4$
	(a) NaCl solution	White ppt.
	(a) NaOU solution

 $\begin{array}{c} \text{Ca(OH)}_2 \, + \, \text{CO}_2 \longrightarrow \begin{array}{c} \text{CaCO}_3 \, + \, \text{H}_2\text{O} \end{array} ] \\ \text{Milkiness} \end{array}$ 

### **Objective Questions for IIT ASPIRANTS**

		-	
1.	Which of the following pairs of ions would be expected to	13.	$[X] + H_2SO_4 \longrightarrow [Y]$ a colourless gas with irritating smell,
	form precipitate when their dilute solutions are mixed?		$[Y] + K_2Cr_2O_7 + H_2SO_4 \longrightarrow$ Green solution. [X] and [Y] are:
	(a) $Na^+$ , $SO_3^{2-}$ (b) $NH_4^+$ , $CO_3^{2-}$		(a) $SO_3^{2-}$ and $SO_2$ (b) $Cl^-$ and $HCl$
	(c) $Na^+, S^{2-}$ (d) $Fe^{3+}, PO_4^{3-}$		(c) $S^2$ and $H_2S$ (d) $CO_2^3$ and $CO_2$
2.	An orange precipitate in the second group is given by:	1.1	
	(a) $Sb^{3+}$ (b) $Sn^{2+}$ .	14.	An aqueous solution containing Hg <sup>2+</sup> , Hg <sup>2+</sup> , Pb <sup>2+</sup> and Cd <sup>2+</sup>
		\ .	ions will give precipitates of with HCl.
	(c) $Hg^{2+}$ (d) $As^{3+}$	\ <u>'</u>	(a) Hg <sub>2</sub> Cl <sub>2</sub> only (b) PbCl <sub>2</sub> only (c) Hg <sub>2</sub> Cl <sub>2</sub> and PbCl <sub>2</sub> (d) HgCl <sub>2</sub> and PbCl <sub>2</sub>
3.	$Mn^{2+} + PbO_2 \xrightarrow{conc. HNO_3} $ light purple coloured solution	15	A solution of salt/salts in HCl when diluted with water turns
	contains:	13.	milky. It indicates the presence of:
	(a) $HMnO_4$ (b) $Pb(NO_3)_2$		(a) Sn salt (b) Bi salt
*	(c) $Mn(NO_3)_2$ (d) $H_2MnO_4$		(c) Sb salt (d) Cu salt
. (	Fused with $Na_2CO_3$ (H <sub>2</sub> SO <sub>4</sub> +H <sub>2</sub> O)	16	Ammonium salt gives brown colour with alkaline solution of
4.	$(A) \xrightarrow{\text{Fused with Na}_2\text{CO}_3} (B) \xrightarrow{\text{(H}_2\text{SO}_4 + \text{H}_2\text{O})} (C)$ Green solid Yellow Orange		Nessler's reagent to form iodide of Millon's base. The formula
	solution Tellow		of this compound is:
	(CH <sub>3</sub> COO) <sub>2</sub> Pb		(a) NH <sub>2</sub> —Hg—O—Hg—I (b) NH <sub>2</sub> —O—Hg—HgI
	(D) Yellow ppt.		(c) $K_2HgI_4$ (d) $NH_2-Hg-I$
	Here, $A$ , $B$ , $C$ and $D$ are respectively:	17.	H <sub>2</sub> S gas is passed into zinc acetate and zinc chloride
	A' , $B$ $C$ $D$	_	solutions in separate test tubes (I) and (II). The ZnS is
	(a) FeSO <sub>4</sub> FeCO <sub>3</sub> Fe(OH) <sub>3</sub> PbCO <sub>3</sub>		precipitated in:
	(b) Cr <sub>2</sub> O <sub>3</sub> Na <sub>2</sub> CrO <sub>4</sub> Na <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub> PbCrO <sub>4</sub>		(a) (I) (b) (II)
	(c) FeCl <sub>2</sub> FeSO <sub>4</sub> PbSO <sub>4</sub> Fe(OH) <sub>3</sub>		(c) both (d) none of these
	(d) FeSO <sub>4</sub> FeCl <sub>3</sub> Fe(OH) <sub>3</sub> PbCl <sub>2</sub>		[Hint: ZnS is precipitated in weak acid or alkaline solution.]
5.		18.	Which give/gives a black precipitate when H <sub>2</sub> S is passed
	on heating?		through an acidic solution of ?
	(a) CuCO <sub>3</sub> (b) Ag <sub>2</sub> CO <sub>3</sub>		(a) Nickel acetate . (b) Copper acetate
	(c) $Na_2CO_3$ (d) $MgCO_3$	•	(c) Cobalt acetate (d) Lead acetate
6.	The sulphide, which is insoluble in 50% HNO <sub>3</sub> is:	<b>19.</b>	Which of the following ions can be detected by flame test?
	(a) HgS (b) CuS	•	(a) $K^{+}$ (b) $Ba^{2+}$
•	(c) Bi <sub>2</sub> S <sub>3</sub> (d) PbS		(c) $Ca^{2+}$ (d) $Mg^{2+}$
7.	The ions which can be precipitated with both HCl and H <sub>2</sub> S.	20.	,,
	are:		(a) $Mg^{2+}$ (b) $Mn^{2+}$
• '	(a) $Pb^{2+}$ (b) $Cu^{2+}$		(c) $Cu^{2+}$ (d) $Pb^{2+}$
	(c) $Ag^+$ (d) $Sn^{2+}$	21.	A colourless salt 'A' $\xrightarrow{\text{MnO}_4^-/\text{H}^+}$ Decolourisation of
8.	Which of the following are soluble in water?	,	permanganate solution occurs
	(a) $CaC_2O_4$ (b) $SrSO_4$		permanganate solution occurs
	(c) $BaCl_2$ (d) $(NH_4)_2C_2O_4$	•	$\xrightarrow{\text{Heat}} X + Y + Z;  Z \xrightarrow{\text{H}_2\text{O}} B'$
9.	Salt of which of the following radicals will give brown fumes		
	when treated with conc. HNO <sub>3</sub> ?		Gases
	(a) $NO_3^-$ (b) Br		Gas $Y \rightarrow B \longrightarrow Milkiness$
	(c) $\Gamma$ (d) $Cl^-$		Gas X burns with blue flame. Mark the correct choice.
10.	Which of the following halides are not soluble in water?		$A \qquad X \qquad Y \qquad Z \qquad B$
	(a) AgCl (b) AgBr		(a) $CaCO_3$ CO $CO_2$ CaO $Ca(OH)_2$
	(c) PbCl <sub>2</sub> (d) AgF		(b) $CaC_2O_4$ CO $CO_2$ CaO $Ca(OH)_2$
11.	Aqueous solution of KI is used to detect:		(c) CaC <sub>2</sub> O <sub>4</sub> CO <sub>2</sub> CO CaO Ca(OH) <sub>2</sub>
	(a) $Hg^{2+}$ (b) $Pb^{2+}$		(d) $CaOCl_2$ $Cl_2$ $O_2$ $CaO$ $Ca(OH)_2$
10	(c) $Ag^+$ (d) $Be^{3+}$		[Hint: $CaC_2O_4 \longrightarrow CO + CO_2 + CaO$ ;
12.	Potassium chromate ( $K_2CrO_4$ ) is used to identify:		$(A) \qquad (X)  (Y)  (Z)$
	(a) $Pb^{2+}$ (b) $Ba^{2+}$ (c) $Aa^{+}$ (d) $Ca^{2+}$		$CaO + H_2O \longrightarrow Ca(OH)_2$
	101 A II		(T)

22. Conc. H2SO4 Brown fumes Colourless salt 'A' Blue solution + metal 'C' White ppt. soluble in NH<sub>4</sub>OH The salt 'A' is: (a)  $Cu(NO_3)_2$ (b) Pb(NO<sub>3</sub>)<sub>2</sub> (c) AgNO<sub>3</sub> (d)  $Zn(NO_3)_2$ [Hint:  $2AgNO_3 + H_2SO_4 \rightarrow Ag_2SO_4 + 2NO_2 + H_2O + \frac{1}{2}O_2$  $2AgNO_3 + Cu \longrightarrow Cu(NO_3)_2 + 2Ag$ 3. (a) 4. (b) 5. (b,c) **6.** (a)

 $AgNO_3 + HCl \longrightarrow AgCl + HNO_3$ White ppt. soluble in NH4OH 23. NaCl +  $K_2Cr_2O_7$  + Conc.  $H_2SO_4 \xrightarrow{\text{Heat}}$  Red coloured gas  $X \leftarrow \frac{\text{CH}_3\text{COOH}}{\text{Pb}(\text{CH}_3\text{COO})_2} - \text{Yellow} \leftarrow \text{Solution}$ NaOH solution The formula and colour of X is: (a) CrO<sub>2</sub>Cl<sub>2</sub>, red (b)  $Cr_2(SO_4)_3$ , green (c) PbO, yellow (d) PbCrO<sub>4</sub>, vellow [Hint: Chromyl chloride test]

7. (a,c) 8. (c,d) **9.** (a,b) 10. (a,b,c)11. (a,b,c) 12. (a,b,c) 13. (a) 14. (c) 15. (a,b,c) 16. (a) **18.** (b,d) **19.** (a,b,c) **20.** (d) **21.** (b) **22.** (c) 23. (d) 17. (a)

### Matrix Matching Questions for IIT Aspirants

(a-s)

(a-p, q) (a-p, s) (b-r)

(b-s)

(b-r, s)

1. Match the reagents (List-II) with their uses (List-II):

List-I	List-II
(Reagents)	(Uses)
(a) Nessler's reagent	(p) Chromyl chloride test
(b) $K_2Cr_2O_7$	(q) Prussian blue test of Fe <sup>3</sup>
(c) NaOH	(r) Chocolate brown test of
(d) $K_4[Fe(CN)_6]$	(s) NH <sub>4</sub> ion
Motob the radicals of List I	with their groups of List II.

Match the radicals of List-I with their groups of List-II:

List-II List-I (a) Pb<sup>2+</sup> (p) Ist group (b) Cu<sup>2+</sup> (q) Zero group (c) NH<sub>4</sub><sup>+</sup> (r) 3rd group (d)  $Al^{3+}$ (s) 2nd group 3. Match the sulphates of List-I with their properties of List-II: List-I List-II (a) CuSO<sub>4</sub>·5H<sub>2</sub>O (p) Water insoluble

(c) BaSO<sub>4</sub> (r) Blue coloured (s) White residue (in solid state) (d)  $Ag_2SO_4$ Match the radicals of List-I with their group reagents of List-II: · List-II List-I

(q) Water soluble

(a) Pb<sup>2+</sup> (p) H<sub>2</sub>S (b) Co<sup>2+</sup>  $(q) (NH_4Cl + NH_4OH)$ (c)  $Fe^{3+}$ (r) HCl (d)  $Ba^{2+}$ (s)  $(NH_4)_2CO_3$ 

5. Match the metals in List-I with their flame colour in List-II:

#### List-I List-II (a) Lithium (p) Violet (b) Barium (q) Brick red (c) Calcium (r) Apple green (d) Magnesium (s) Crimson red (t) No flame colour

	(t) No name colour				
6.	Match the observations of List-I with inferences in List-II:				
	List-I	List-II			
*	(a) Canary yellow precipitate with ammonium molybdate.	(p) PO <sub>4</sub> <sup>3-</sup>			
	(b) Ring test (Brown)	(q) $As^{3+}$			
	(c) Acid radical decomposed	(r) NO <sub>3</sub>			
	by dil. H <sub>2</sub> SO <sub>4</sub>				
	(d) Acid radical decomposed	(s) NO <sub>2</sub>			
	by conc. H <sub>2</sub> SO <sub>4</sub>				
7.	Match List-I with List-II				
	List-I	List-II			
	(Sulphides)	(Colour/group)			
	(a) HgS	(p) 2nd group of basic radicals			
	(b) NiS	(q) Buff-colour			
	(c) MnS	(r) Dirty white			
	(d) ZnS	(s) Black			
		•.			
	•

(d-t)

(d-r, s)

(d-r)

(b) PbSO<sub>4</sub>

1.	(a-s)	(b-p)	(c-s)		$(\mathbf{d}-\mathbf{q}, \dot{\mathbf{r}})$	
2.	(a-p, s)	(b-s)	(c-q)	*	(d-r)	•
3.	(a-q, r)	(b-p, s)	(c-p, s)		(d-q, s)	,
4.	(a-p, r)	(b-q, p).	(c-q)		(d-q, s)	

# **Assertion-Reason Type Questions**

The following questions consist of two statements as Assertion (A) and Reason (R). While answering these questions choose correctly any one of the following responses.

- (a) If both (A) and (R) are true and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are true but (R) is not the correct explanation of (A).
- (c) If (A) is true but (R) is false.
- (d) If (A) is false but (R) is true.
- (e) If both (A) and (R) are false.
- 1. (A) CdS and As<sub>2</sub>S<sub>3</sub> both have yellow colour and precipitated by passing H<sub>2</sub>S through solution in dilute HCl.
  - (R) Both can be separated by yellow ammonium sulphide.
- 2. (A) Sulphur dioxide turns acidified potassium dichromate solution green.
  - (R) Sulphur dioxide is a reducing agent. It reduces acidified potassium dichromate into chromic compound which is green in colour.
- (A) Original solution for basic radicals can be prepared in concentrated HNO<sub>3</sub> or concentrated H<sub>2</sub>SO<sub>4</sub>.

- (R) Both the acids dissolve majority of inorganic salts.
- (A) Ammonium salts evolve ammonia when heated with NaOH.
  - (R) Ammonium salts are soluble in water.
- 5. (A) Chloride is confirmed by chromyl chloride test.
  - (R) Chlorine is evolved when chloride is heated with conc. H<sub>2</sub>SO<sub>4</sub>.
- **6.** (A) PbCl<sub>2</sub> and Hg<sub>2</sub>Cl<sub>2</sub> precipitates can be separated by hot water.
  - (R) Aqueous solution of PbCl<sub>2</sub> gives yellow precipitate with K<sub>2</sub>CrO<sub>4</sub> solution.
- (A) When Cl<sub>2</sub> gas is passed into a mixture containing Br
  and I and CHCl<sub>3</sub>, I<sub>2</sub> (violet) first appears in CHCl<sub>3</sub> layer.
  - (R) In excess of Cl<sub>2</sub> gas, violet colour disappears and CHCl<sub>3</sub> layer becomes brown.
- 8. (A) When H<sub>2</sub>S gas is passed into aqueous solution of ZnCl<sub>2</sub>, white precipitate of ZnS appears.
  - (R) ZnS is insoluble in HCl.

# THOUGHT TYPE QUESTIONS

#### **THOUGHT 1**

Answer the following questions:

- 1. Compound (A) is:
  - (a) CuSO<sub>4</sub>

- (b) AgNO<sub>3</sub>
- (c) Pb(NO<sub>3</sub>)<sub>2</sub>
- (d) Ca(NO<sub>3</sub>)<sub>2</sub>
- 2. Yellow precipitate (B) is:
  - (a) AgI

(b) PbI<sub>2</sub>

(c) Cal<sub>2</sub>

- (d) CH<sub>3</sub>I
- 3. White precipitate (C) obtained on treatment with aqueous solution of BaCl<sub>2</sub>, is:
  - (a) BaSO<sub>4</sub>
- (b) AgCl

(c) PbCl<sub>2</sub>

(d) CaCl<sub>2</sub>

- 4. The compound (D) obtained, when (C) dissolves in excess of NH<sub>4</sub>OH will be:
  - (a) AgOH

(b) [Ag(NH<sub>3</sub>)<sub>2</sub>Cl]

(c) Ag<sub>2</sub>O

- (d) AgNO<sub>3</sub>
- 5. Molecular formula of the compound 'E'; is:
  - (a)  $Ag_2O$

(b)  $Pb(OH)_2$ 

(c) AgOH

(d) Ca(OH)<sub>2</sub>

#### **THOUGHT 2**

A bluish green coloured compound (A), on thermal decomposition gives two products (B) and (C). When  $H_2$  gas is passed through (B) under hot conditions then a metal (D) is obtained. Both (A) and (B) are insoluble in water. Compound (B) is black coloured and gives chocolate brown precipitate (E) on treatment with  $K_4[Fe(CN)_6]$ . Compound (C) is colourless, odourless gas and it turns limewater milky.

Indicate whether following statements are true or false:

- 1. Compound (A) is CuCO<sub>3</sub>:
  - (a) True

(b) False

2. The black salt (B) is PbS:

(a) True

(b) False

3. The gaseous compound (C) is  $CO_2$ :

(a) True

(b) False

**4.** The metallic element (D) is copper:

(a) True

(b) False

5. The chocolate brown precipitate (E) is of  $Fe_4[Fe(CN)_6]_3$ :

(b) False

#### THOUGHT 3

A mixture contains four gases CO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub> and O<sub>2</sub>. Following four reagents are given for the detection of these gases:

- (a) Lime water
- (b) Acidified potassium dichromate
- (c) Pyrogallol
- (d) Turpentine oil

- 1. Which of the following gases will turn limewater milky?
  - (a) CO<sub>2</sub>

(b) SO<sub>2</sub>

(c)  $O_2$ 

(d)  $O_3$ 

Which of the following gases will turn acidified potassium dichromate green?

(a)  $CO_2$ 

(b) SO<sub>2</sub>

(c) O<sub>2</sub>

(d) O<sub>2</sub>

3. The gas which is absorbed in pyrogallol, is:

(a)  $CO_2$ 

(b) SO<sub>2</sub>

(c) O<sub>2</sub>

(d) O<sub>3</sub>

4. The gas which is absorbed in turpentine oil, is:

(a) CO<sub>2</sub>

(b) SO<sub>2</sub>

(c) O<sub>2</sub>

(d) O<sub>3</sub> 5. The gas which developes cracks in rubber, is:

(a) O<sub>2</sub>

(b) O<sub>2</sub>

(c) CO<sub>2</sub>

(d) SO<sub>2</sub>

## 

### BRAIN STORMING PROBLEMS

1. A mineral 'A' gave following reactions. Identify the compounds 'A' to 'H' on the basis of road map.

$$A'$$
  $\xrightarrow{\text{Dil.H}_2\text{SO}_4}$   $B'$  +  $C'$  + a gas  $D'$ 

 $(CH_3COO)_2Pb + 'D' \longrightarrow Black precipitate$ 

 $B' + C' \xrightarrow{D'} E'$  (another black precipitate)

('C' remains unaffected)

 $E' + HNO_3 \xrightarrow{\Delta} F'$  blue coloured solution

 $F' + K_4[Fe(CN)_6] \longrightarrow Chocolate brown precipitate$ 

 $C' + K_3 Fe(CN)_6 \longrightarrow H'$  blue coloured

[Ans.  $A: CuFeS_2, B: CuSO_4, C: FeSO_4,$ 

 $D: H_2S, E: CuS, F: Cu(NO_3)_2, G: Cu_2 [Fe(CN)_6]$ 

 $H: KFe[Fe(CN)_6] \rightarrow Turnbull's blue]$ 

2. A gas 'X' occupies 22.4 litre at S.T.P., its weight is 64 g. The gas turns acidified K2Cr2O7 green and decolourise acidified KMnO<sub>4</sub> solution. White turbidity appears when H<sub>2</sub>S gas is passed through aqueous solution of gas. What is the gas 'X'? Explain the reactions involved.

[Ans. SO<sub>2</sub>]

Hint:

(i)  $K_2Cr_2O_7 + H_2SO_4 + SO_2 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O$ 

(ii)  $2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$  $5SO_2 + 5H_2O + 5[O] \longrightarrow 5H_2SO_4$ 

 $2KMnO_4 + 3H_2SO_4 + 5SO_2 + 2H_2O \longrightarrow K_2SO_4 + 2MnSO_4 + 5H_2SO_4$ 

(iii) 
$$2H_2S + SO_2 \longrightarrow 2H_2O + 3S$$
 ]  
(White turbidity)

3. Aqueous solution of salt 'A' gives white precipitate of 'B' with NaCl solution. The filtrate gives black precipitate 'C' on passing H<sub>2</sub>S gas through it. Compound 'B' dissolves in hot water and the solution gives yellow precipitate 'D' on treatment with KI. Compound 'A' gives reddish brown fumes on heating. Identify the compounds 'A' to 'D'. [Ans. (A)  $Pb(NO_3)_2$ ; (B)  $PbCl_2$ ; (C) PbS; (D)  $PbI_2$ ]

4. 
$$[A]$$
  $\xrightarrow{KOH}$   $A$   $B$ 

Colourless Gas, giving white fumes with HCl

 $CaCl_2$ 
 $CaCl_2$ 

White precipitate, decolourises pink colour of acidified KMnO<sub>4</sub>.

What are [A], [B] and [C]? Give the reactions involved.

[Ans. (A)  $(NH_4)_2C_2O_4$ ; (B)  $NH_3$ ; (C)  $CaC_2O_4$ ]

[Hint: 
$$(NH_4)_2C_2O_4 + 2KOH \xrightarrow{\Delta} \begin{vmatrix} COOK \\ -\Delta \end{vmatrix} + 2NH_3 + 2H_2O$$

$$(NH_4)_2C_2O_4 + CaCl_2 \xrightarrow{CaC_2O_4} - 2NH_4Cl$$
White precipitate

$$CaC_2O_4 + H_2SO_4 \longrightarrow CaSO_4 + \begin{vmatrix} COOH \\ COOH \\ Oxalic acid \end{vmatrix}$$

$$CooH$$

$$Oxalic acid decolourises acidified KMnO_4.$$

$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$

$$COOH$$

$$5 \begin{vmatrix} +5[O] \longrightarrow 10CO_2 + 5H_2O \\ COOH \end{vmatrix}$$

$$2KMnO_4 + 5H_2C_2O_4 + 3H_2SO_4 \longrightarrow K_2SO_4 \\ + 2MnSO_4 + 10CO_2 + 8H_2O_4 = 2MnSO_4 + 2MnSO_5 + 2MnS$$

- 5. An element 'A' on treatment with water evolves a colourless gas 'B' and gives a solution of 'C'. Lithium reacts with 'B' to form 'D'. Compound 'D' reacts with water to form a basic solution of 'E' and a gas 'F'. By passing CO<sub>2</sub> gas through the solution of 'C', it gives white precipitate of 'G' which dissolves in excess of CO<sub>2</sub> to form solution of 'H'. Precipitate 'G' gives deep red colour to the Bunsen burner flame. What are the compounds 'A' to 'H' and give the reactions involved?

  [Ans. (A) Ca; (B) H<sub>2</sub>; (C) Ca(OH)<sub>2</sub>; (D) LiH; (E) LiOH; (F) H<sub>2</sub>; (G) CaCO<sub>3</sub>; (H) Ca(HCO<sub>3</sub>)<sub>2</sub>]
- 6. A binary oxide (A) of alkaline earth metal when treated with HCl gives solid (B) and solution of (B). (B) gives apple green colour to the Bunsen flame. Solution of (C) decolourises acidified KMnO<sub>4</sub>. What are (A), (B) and (C)?

[Ans. (A) 
$$BaO_2$$
; (B)  $BaCl_2$ ; (C)  $H_2O_2$ ]

[Hint: 
$$BaO_2 + 2HCl \longrightarrow BaCl_2 + H_2O_2$$
(A)
(B)
(C)
$$2KMnO_4 + 3H_2SO_4 \longrightarrow K_2SO_4 + 2MnSO_4 + 3H_2O + 5[O]$$

$$5H_2O_2 + 5[O] \longrightarrow 5H_2O + 5O_2$$

$$2KMnO_4 + 3H_2SO_4 + 5H_2O_2 \longrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O + 5O_2$$

7. A colourless salt 'A' decolourises the pink colour of iodine. Solution of 'A' on treatment with AgNO<sub>3</sub> gives white precipitate. The compound 'A' turns FeCl<sub>3</sub> solution (yellow) to FeCl<sub>2</sub> solution (green). Identify 'A' and give the reactions involved.

[Ans. The compound 'A' is  $Na_2S_2O_3$ , i.e., sodium thiosulphate.] [Hint:  $2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$ 

$$Na_2S_2O_3 + 2AgNO_3 \longrightarrow 2NaNO_3 + Ag_2S_2O_3$$
  
White precipitate

$$2\text{FeCl}_3 + 2\text{Na}_2\text{S}_2\text{O}_3 \longrightarrow 2\text{FeCl}_2 + \text{Na}_2\text{S}_4\text{O}_6 + 2\text{Na}^2\text{Cl}_2$$

8. Compound 'A' reduces HgCl<sub>2</sub> to a white precipitate, turning to grey. Solution of 'A' turns yellow coloured solution of FeCl<sub>3</sub> to a green coloured solution. Solution of 'A' gives white precipitate with NaOH, which dissolves in excess of NaOH. Moreover, the solution of 'A' gives yellow precipitate, when H<sub>2</sub>S gas is passed through it. This precipitate dissolves in yellow ammonium sulphide. Compound 'A' is found to give chromyl chloride test. Identify the compound 'A' and give the reactions involved.

Ans. Compound 'A' is 
$$SnCl_2$$
.

 $SnCl_2 + 2HgCl_2 \longrightarrow Hg_2Cl_2 + SnCl_4$ 
White

 $SnCl_2 + Hg_2Cl_2 \longrightarrow 2Hg + SnCl_4$ 
 $Grey$ 
 $SnCl_2 + 2FeCl_3 \longrightarrow SnCl_4 + 2FeCl_2$ 
 $Green$ 
 $SnCl_2 + 2NaOH \longrightarrow Sn(OH)_2 + 2NaCl$ 
 $(White precipitate)$ 
 $Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$ 
 $Soluble$ 
 $SnCl_2 + H_2S \longrightarrow 2HCl + SnS$ 
 $Yellow$ 
 $SnS + (NH_4)_2S_2 \longrightarrow (NH_4)_2SnS_3$  ]
 $Yellow$ 
 $SnS + (NH_4)_2S_3 \longrightarrow Soluble$ 
 $SnCl_2 + M_2S \longrightarrow Soluble$ 
 $SnS + (NH_4)_2S_3 \longrightarrow Soluble$ 
 $SnS + (NH_4)_2S_3 \longrightarrow Soluble$ 

9. 
$$[A] \xrightarrow{\text{HNO}_3} [B] + [C] \xrightarrow{\text{KI or } \text{K}_2\text{CrO}_4} \text{Yellow precipitate}$$

Scarlet Black Colourless solution residue  $H_2\text{S gas}$ 

(E)  $H_2\text{S gas}$ 
(D) Black precipitate

Pink of it dissolves coloured in dil. HNO<sub>3</sub> solution

What are the compounds 'A' to 'E' in above road map problem? Give the reactions involved.

[Ans. (A) 
$$Pb_3O_4$$
; (B)  $PbO_2$ ; (C)  $Pb(NO_3)_2$ ; (D)  $PbS$ ; (E)  $HMnO_4$ ]

$$[ \textbf{Hint} : Pb_3O_4 + 4HNO_3 \longrightarrow PbO_2 + 2Pb(NO_3)_2 + 2H_2O$$

$$(A) \qquad (B) \qquad (C)$$

$$Pb(NO_3)_2 + 2KI \longrightarrow PbI_2 + 2KNO_3$$
 $Yellow$ 
precipitate

$$Pb(NO_3)_2 + K_2CrO_4 \longrightarrow PbCrO_4 + 2KNO_3$$
  
Yellow

$$Pb(NO_3)_2 + H_2S \longrightarrow PbS + 2HNO_3$$
(D) Black precipitate

$$PbO_2 + Mn^{2+} + HNO_3 \longrightarrow HMnO_4 + Pb^{2+}$$
]

10. A hydrated metallic salt (A), light green in colour, gives a white anhydrous residue (B) after being heated gradually. (B) is soluble in water and its aqueous solution reacts with NO to give a dark brown compound (C). (B) on strong heating gives a brown residue (D) and a mixture of two gases (E) and (F). The gaseous mixture, when passed through acidified permanganate, discharges the pink colour and when passed through acidified BaCl<sub>2</sub>, gives a white precipitate. Identify (A), (B), (C), (D), (E) and (F).

[Ans. (A) 
$$FeSO_4.7H_2O$$
; (B)  $FeSO_4$ ; (C)  $FeSO_4.NO$   
(D)  $Fe_2O_3$ ; (E)  $SO_2$ ; (F)  $SO_3$ ]

# Revision Exercise (Chapter 16 to 18)

	GLE CORRECT ANSWER TYPE		(a) 100L □ (b) 250L □ (c) 50 mole □ (d) 250 mole □	٦. ٢
1.	Chlorine is prepared by reacting HCl with MnO <sub>2</sub> . The	9.	50 mL of a mixture of CO and H <sub>2</sub> gave 20 mL of CO <sub>2</sub> after	
	reaction is represented by the following equation:	,	combustion in excess of air. What is the percentage of CC	
	$MnO_2 + 4HCl \longrightarrow Cl_2 + MnCl_2 + 2H_2O$		by volume in the mixture?	•
	Assuming the reaction goes to completion, what mass of		(a) 40	ב

$\longrightarrow$ Fe <sub>2</sub> (SO <sub>4</sub> ) <sub>3</sub> + H <sub>2</sub> O				

(t) NH<sub>4</sub> ion

#### INTEGER ANSWER TYPE

- **42.** 13.4 g of a sample of a salt  $Na_2SO_4 \cdot xH_2O$  was found to contain 6.3 g of water. What is the value of x?
- **43.** 17 g of pure H<sub>2</sub>O<sub>2</sub> is decomposed. The mass of oxygen evolved is:
- 44. A mixture of marsh gas (CH<sub>4</sub>) and acetylene requires 22 mL of oxygen for complete combustion and produces 14 mL of CO<sub>2</sub>. What is the volume of marsh gas in the mixture?
- **45.** 4 moles of H<sub>2</sub>S and 22.4 L of SO<sub>2</sub> at STP react according to following equation,

$$SO_2 + 2H_2S \longrightarrow 2H_2O + 3S$$

What will be the number of moles of sulphur formed in the reaction?

- **46.** 4.9 g of H<sub>2</sub>SO<sub>4</sub> is present in 100 mL of the solution. What is the normality of the solution?
- 47. 0.175 g of a metal was dissolved in 50 mL N-acid. The whole solution required 20.85 mL of normal alkaline solution to neutralise the excess of acid. What is the equivalent mass of the metal?
- 48. What is the mass in grams of available O<sub>2</sub> per litre from a solution of H<sub>2</sub>O<sub>2</sub>, 5 mL of which when titrated with N/20 KMnO<sub>4</sub> solution required 25 mL for the reaction.

  2KMnO<sub>4</sub> + 5H<sub>2</sub>O<sub>2</sub> + 4H<sub>2</sub>SO<sub>4</sub> → 5O<sub>2</sub> + 8H<sub>2</sub>O

+ 2KHSO<sub>4</sub> + 2MnSO<sub>4</sub>

#### LINKED COMPREHENSION TYPE

#### Passage 1

Compound 'A' reduces  $HgCl_2$  to a white precipitate, turning to grey. Solution of 'A' gives white precipitate with NaOH, which dissolves in excess of NaOH. The solution of 'A' in dilute HCl gives yellow precipitate on passing  $H_2S$ . Compound 'A' mixed with  $K_2Cr_2O_7$  and heated with conc.  $H_2SO_4$  gives vapours which when passed through NaOH solution form yellow coloured solution.

- **49.** Compound 'A' is:
  - (a) CdCl<sub>2</sub>

(b) PbCl<sub>2</sub>

(c) SnCl<sub>2</sub>

- (d) BiCl<sub>3</sub>
- **50.** The precipitate formed by NaOH with solution of 'A' is:
  - (a) Sn(OH)Cl
- (b)  $Sn(OH)_2$

(c) SnO

- (d) SnO<sub>2</sub>
- **51.** The vapours evolved when compound 'A' is heated with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and conc. H<sub>2</sub>SO<sub>4</sub> are:
  - (a) chlorine
- (b) chlorine dioxide
- (c) hydrogen chloride
- (d) chromyl chloride
- **52.** Compound 'A' gives white ppt. with HgCl<sub>2</sub>. The name of white compound is:
  - (a) Calomel
- (b) Corrosive sublimate
- (c) Vermilon
- (d) Millon's base

#### Passage 2

Compound 'A' is a light green solid. It gives the following tests.

- (a) It dissolves in dilute H<sub>2</sub>SO<sub>4</sub>. No gas is evolved.
- (b) Compound 'A' is heated strongly. Two gases (B) and (C) with pungent smell come out and brown residue (D) is left.
- The gaseous mixture is passed into acidified K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solution, it turns green.
- (d) The residue 'D' from reaction (b) on boiling with HCl acid gives a vellow solution 'E'. The vellow solution on treatment with ammonium thiocyanate gives a blood red solution.
- **53.** Compound 'A' shows reducing properties.
  - (a) FeSO<sub>4</sub>
- (b) NiSO<sub>4</sub>
- (c)  $Cr_2(SO_4)_3$
- (d)  $Fe_2(SO_4)_3$
- 54. The residue 'D' is:
  - (a) Cr<sub>2</sub>O<sub>3</sub>

(b) NiO

- (c)  $Fe_2O_3$
- (d) FeO
- **55.** The solution 'E' contains:
  - (a) FeCl<sub>2</sub>

(b) FeCl<sub>3</sub>

(c) CrCl<sub>3</sub>

(d) NiClo

# fuswers with Hints

1. (c) 
$$MnO_2 + 4HCl \longrightarrow Cl_2 + MnCl_2 + 2H_2O$$
  
 $4 \times 36.5 \text{ g}$  71 g

HCl needed for 7 g Cl<sub>2</sub> = 
$$\frac{4 \times 36.5}{71} \times 7 = 14.39$$
 g

36% HCl soln. required = 
$$\frac{100}{36} \times 14.39 \approx 40$$

$$Ag_2CO_3 \longrightarrow 2Ag + CO_2 + \frac{1}{2}O_2$$
276 g, 216 g

Residue obtained from 5.2 g Ag<sub>2</sub>CO<sub>3</sub> =  $\frac{216}{276} \times 5.2 = 4.07$ 

3. (a) 30 mL 0.1 
$$M$$
 Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 30 mL 0.1  $N$  Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>  
= 30 mL 0.1  $N$  Cl<sub>2</sub>  
= 30 mL 0.1  $N$  MnO<sub>2</sub>

Amount of MnO<sub>2</sub> = 
$$\frac{87}{2} \times \frac{0.1}{1000} \times 30 = 0.1305$$
 g

% of MnO<sub>2</sub> = 
$$\frac{0.1305}{0.5} \times 100 = 26.1$$

4. (a) Let xL of A be mixed with (2-x) L of B.

$$x \times (0.5) + (2 - x) \times (0.1) = 2 \times (0.2)$$

$$x = \frac{0.2}{0.4} = 0.5$$

5. (d) 
$$Cu_2O \longrightarrow 2Cu$$

$$144 g = 2 \times 6$$

$$= 128$$

$$CuO \longrightarrow Cu$$

Let 'a' g  $Cu_2O$  and (100 - a)g CuO be present in 100 g of the mixture.

$$\frac{128}{144} \times a + \frac{64}{80} \times (100 - a) = 88$$

$$a = 90$$

#### Passage 3

1.325 g of anhydrous sodium carbonate are dissolved in water and the solution made upto 250 mL. On titration, 25 mL of this solution neutralise 20 mL of sulphuric acid.

- 56. Normality of Na<sub>2</sub>CO<sub>3</sub> solution is:
  - (a) 1 N

(b) 0.1 N

(c) 0.5 N

- (d) 0.01 N
- 57. Normality of the sulphuric acid solution is:
  - (a) 1/2

(b) 1/4

(c) 1/8

- (d) 1/16
- 58. How much water be added to 450 mL of the H<sub>2</sub>SO<sub>4</sub> solution to make it exactly N/12?

 $Cu_2O = \frac{90}{100} \times 5 = 4.5 g$ 

Strength of the soln.  $=\frac{4.9}{100} \times 1000 = 49$ 

7. (c) No. of g equivalents of AgCl obtained =  $\frac{0.1435}{1435} = 0.001$ 

Number of moles of isooctane =  $\frac{2280}{114}$  = 20

(d) Mass of petrol =  $2850 \times 0.8 = 2280$  g

 $CuO = \frac{10}{100} \times 5 = 0.5 \text{ g}$ 

Molarity =  $\frac{\text{Strength}}{\text{Mol. mass}} = \frac{49}{98} = 0.5$ 

Thus, 20 mL of HCl contains 0.001 g equivalents of HCl.

Normality =  $\frac{0.001}{20} \times 1000 = 0.05 N$ 

 $C_8H_{18} + \frac{25}{2}O_2 \longrightarrow 8CO_2 + 9H_2O$ 1 mole 25/2 mole 25/2 mole

Normality =  $2 \times Molarity = 2 \times 0.5 = 1.0$ 

- (a) 225 mL
- (b) 125 mL
- (c) 175 mL
- (d) 200 mL

- 2. (b) Ag<sub>2</sub>CO<sub>3</sub> on strong heating gives silver metal.

$$Ag_2CO_3 \longrightarrow 2Ag + CO_2 + \frac{1}{2}O$$
276 g. 216 g

Amount of MnO<sub>2</sub> = 
$$\frac{87}{2} \times \frac{0.1}{1000} \times 30 = 0.1305 \text{ g}$$

$$x = \frac{0.2}{0.1} = 0.5$$

(a)  $\underset{1 \text{ vol}}{\text{CO}} + \frac{1}{2} \text{O}_2 \longrightarrow \underset{1 \text{ vol}}{\text{CO}_2}$ 

$$\% = \frac{20}{50} \times 100 = 40$$

- 11. (b) AgCl—It is a covalent chloride. It dissolves in ammonium hydroxide and forms a complex which is soluble.

$$AgCl + 2NH_4OH \longrightarrow Ag(NH_3)_2Cl + 2H_2O$$
Soluble

It combines with KI and forms yellow precipitate of AgI.

$$Ag(NH_3)_2Cl + KI \longrightarrow AgI + 2NH_3 + KCl$$

12. (c)  $NH_4NO_2$   $2NH_4NO_2 + H_2SO_4 \longrightarrow (NH_4)_2SO_4 + NO_2 + NO_2 + H_2O$   $NH_4NO_2 + NaOH \longrightarrow NH_3 + NaNO_2 + H_2O$  $NH_4NO_2 \xrightarrow{\text{Heat}} N_2 + 2H_2O$ 

- 13. (d) Oxalate—It gives out mixture of two gases CO<sub>2</sub> and CO. CO<sub>2</sub> turns lime water milky and CO burns with blue flame.
- 14. (c) BaCO<sub>3</sub>

$$BaCO_3 + 2HCl \longrightarrow BaCl_2 + CO_2 + H_2O$$
Clear
Soln.

 $BaCO_3 + H_2SO_4 \longrightarrow BaSO_4 + H_2O + CO_2$ White ppt.

$$BaCO_3 + 2CH_3COOH + K_2CrO_4 \longrightarrow$$
  
 $BaCrO_4 + 2CH_3COO$ 

 $\begin{array}{l} \text{BaCrO}_4 + 2\text{CH}_3\text{COOK} + \text{CO}_2 + \text{H}_2\text{O} \\ \text{Yellow ppt.} \end{array}$ 

15. (d) Sulphite 
$$+ H_2SO_4 \longrightarrow SO_2$$

$$(A) \qquad (B) \qquad (B)$$
 $3SO_2 + K_2Cr_2O_7 + H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + H_2O$ 
Green Solph

- 16. (a) KCN forms cyanide complexes with copper and cadmium salts. The cadmium complex is not stable and combines with H<sub>2</sub>S to form yellow ppt., CdS.
- 17. (d)  $Hg_2^{2+} + H_2S \longrightarrow HgS + Hg + 2H^+$
- (a) Bi(OH)<sub>3</sub> does not dissolve in NaOH. It dissolves in HCl.

$$Bi(OH)_3 + 3HCl \longrightarrow BiCl_3 + 3H_2O$$

$$2BiCl_3 + 3Na_2SnO_2 + 6NaOH \longrightarrow 3Na_2SnO_3 + 2Bi + 6NaCl + 3H_2O$$

$$BiCl_3 + H_2O \longrightarrow BiOC1 + 2HC1$$
White

- 19. (c) (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> cannot be used as it will give white ppt. of barium and strontium sulphates. (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> will give white ppt. if Ba<sup>2+</sup>, Sr<sup>2+</sup> and Ca<sup>2+</sup> ions are present. To suppress the ionisation of NH<sub>4</sub>OH, NH<sub>4</sub>NO<sub>3</sub> can be used if Mn<sup>2+</sup> ion is not present.
- 20. (b) 2KMnO<sub>4</sub>+8H<sub>2</sub>SO<sub>4</sub>+10FeSO<sub>4</sub>——
  2 mole 10 mole 5 mole

$$K_2SO_4 + 2MnSO_4 + 5Fe_2(SO_4)_3 + 8H_2O$$

- 21. (b) The gas SO<sub>2</sub> turns K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> soln. green. The acidic radical present is SO<sub>3</sub><sup>2</sup>.
   Under the conditions, K<sub>3</sub>[Co(CO<sub>3</sub>)<sub>3</sub>] is formed which is apple green in colour. Thus, the salt consists Co<sup>2+</sup> as cation.
- 22. (d) 100 mL 0.2 N NaOH = 100 mL 0.2 N oxalic acid Amount of oxalic acid =  $\frac{63 \times 0.2 \times 100}{1000}$  = 1.26 g
- 23. (d) Amount of iron present in molecular mass of haemoglobin

$$=\frac{0.33}{100} \times 68000 = 0.33 \times 680 \text{ g}$$

Number of iron atoms = 
$$\frac{0.33 \times 680}{56} \approx 4$$

24. (a) 20 mL 0.1 N Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> = 20 mL 0.1 N I<sub>2</sub> = 20 mL 0.1 N Cl<sub>2</sub>

Amount of chlorine = 
$$\frac{35.5 \times 0.1 \times 20}{1000} = 0.071 \text{ g}$$

Amount of chlorine in 500 mL suspension =  $\frac{0.071}{20} \times 500 = 1.775$ 

% available chlorine = 
$$\frac{1.775}{5} \times 100 = 35.5$$

- 25. (c, d)
- **26.** (a, d)
  - (a) The equivalent mass of KMnO<sub>4</sub> in alkaline medium

= Mol, mass

(b) Mass of oxalic acid = 
$$\frac{63 \times 0.02 \times 500}{1000} = 6.3 \text{ g}$$

(c) 
$$K_2Cr_2O_7 + 7H_2SO_4 + 6FeSO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3$$
  
1 mole 6 mole + 3Fe<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub> + 7H<sub>2</sub>O  
0.1 × V = 1/6 [35.0 × 0.5]

$$0.1 \times V = 1/6 [35.0 \times 0.5]$$
  
  $V = 29.17$

- **19.14** Green Chemistry as an Alternative Tool for Reducing Pollution

### 19.1

#### INTRODUCTION

The earth, where various forms of life live and survive under different conditions, is a unique planet of the solar system. This is perhaps partly due to optimum distance of the earth from the sun. The temperature of the earth is neither too hot as in Venus and Mercury nor it is too cold as in Jupiter and other planets. The envelope of air surrounding the earth contains gases and provides oxygen which is essential for survival of most forms of life. The air envelope also regulates the temperature on earth's surface. The moderate temperature conditions also help in the regulation of water in different forms in the atmosphere, as well as on the earth. Thus, earth is a unique planet which has been gifted by nature, a life supporting region known as a biosphere (the environment which supports life and sustains various human activities; it extends to about 20 km from the bottom of the ocean to the highest point in the atmosphere at which life can survive). Various forms of life in the biosphere exist as microbes, plants and animals. These forms of life living in a particular region of biosphere depend on the physical and chemical non-living as well as living components of environment. The non-living components of the environment comprise the atmosphere (air), hydrosphere (water) and lithosphere (land) whereas the living or biological component is biosphere, which includes plants, animals and other organisms. The environment or surroundings of an organism, therefore, includes (i) atmosphere (ii) hydrosphere (iii) lithosphere

and (iv) biosphere. Man on this planet occupies a central position and makes use of other forms of life in the biosphere for various purposes such as food, shelter, etc. It is, thus, essential to study the various components of environment that affect the man and other forms of life on this planet.

Environmental chemistry is defined as the study of chemical phenomenon in the environment or refers to the study of sources, reactions, transport, effects and fates of various chemical species in the air, water and soil environment. Environmental chemistry is not a single disciplinary science but a multidisciplinary science which covers many vastly different fields such as chemistry, physics, biological sciences, agriculture, medical science, public health, sanitary engineering, etc.

The term environmental chemistry has come to be regarded as synonymous with environmental pollution by some scientists. While sticking to this narrow definition, they highlight only the problem of pollution resulting from the varied uses of chemicals yet it must be emphasised that environmental chemistry deals with a wider aspect of knowledge. The problem of pollution is just a small segment of environmental chemistry. The application of energy resources no doubt provided comfort and happiness to man, but it also started degrading his habitat. It soon became apparent that contamination of natural environment threatened

the very existence of mankind, *i.e.*, environmental pollution is becoming a matter of concern for one and all today. A need of conservation of environment is being raised at all national and international levels. Thus, the awareness about various aspects of environment becomes very important for every human being today.

#### 19.2 COMPONENTS OF ENVIRONMENT

#### 1. ATMOSPHERE

It is a protective blanket of gases which is surrounding the earth. The atmosphere extends to thousands of kilometre above the earth's surface. It has no well defined upper limits and gradually merges with the outer space. The atmosphere is held to the earth by the force of gravity. Of the total mass of atmosphere, about 99% is within a height of 30 km from the earth's surface. The total mass of the atmosphere is about  $5 \times 10^{15}$  metric tonnes.

Composition: The constituents which make up the atmosphere are gases, water vapours and aerosols. With increasing height above sea level, the atmospheric pressure gradually decreases. The atmosphere consists relatively uniform composition in the lower layers near the earth if water vapours and aerosols are excluded. The major gases in the air are nitrogen and oxygen. Pure dry air, on an average, constitutes 78% nitrogen and 21% oxygen by volume. Remaining 1% accounts for other gases.

Major components :  $N_2$ ,  $O_2$ , water vapours

Minor components: Ar, CO<sub>2</sub>

Tracer components: He, Ne, Kr, Xe, CH<sub>4</sub>, H<sub>2</sub>, CO, N<sub>2</sub>O, NO, NO<sub>2</sub>, SO<sub>2</sub>, NH<sub>3</sub>, O<sub>3</sub>, HCHO, etc.

The composition of dry atmosphere by volume is given in the following table:

Gas	Per cent	Gas	Per cent
Nitrogen,	78.08	Methane	0.00015
Oxygen	20.95	Nitrous oxide	0.000025
Argon	0.93	Hydrogen	0.00005
Carbon dioxide	0.033	Ozone	0.000004
Neon	0.0018	Xenon	0.000008
Helium	0.00052	Sulphur dioxide,	1
Krypton	0.00011	nitrogen dioxide,	Minute quantities
		ammonia, carbon	
		monoxide, iodine, etc.	

The main constituents of the atmosphere which are responsible for sustaining life on earth are nitrogen, oxygen and carbon dioxide along with water vapour. The constituents which are of great importance for earth's climatic conditions are water vapour dust particles, carbon dioxide and ozone.

Structure or Regions of the Atmosphere: The atmosphere is divided into four major regions depending on the height as shown below:

Region	Height range (km)	Temperature range (°C)	Main constituents
Troposphere	0–11	15 to -56	O <sub>2</sub> , N <sub>2</sub> , H <sub>2</sub> O, CO <sub>2</sub>
Stratosphere	11–50	−56 to −2	O <sub>3</sub>
Mesosphere	50–90	-2 to -92	O <sub>2</sub> <sup>+</sup> , NO <sup>+</sup>
Thermosphere	90–500	-92 to 1200	$O_2^+, O^+, NO^+, N^+$

- (i) Troposphere: It is the lowest region of the atmosphere, *i.e.*, closest to earth's surface. It extends roughly to a height of about 11 km. This is the region of all living organisms including animals and plants. About 70% of the total mass of the atmosphere and practically all the water vapours and dust particles are concentrated in this region. All the dramatic events of weather (rain, lightning, hurricane, etc.), occur in this region. The temperature in this region steadily decreases from ground temperature of about 15°C to about -56°C. The minimum temperature is at about 11 km above earth's surface. This point is called **tropopause.** It contains mainly nitrogen and oxygen. It also contains argon, carbon dioxide, water vapours, aerosols and traces of many other gases. The composition of air in this region remains more or less constant provided there is no significant air pollution.
- (ii) Stratosphere: The next region is stratosphere which extends from 11 km to 50 km. The temperature in this region rises from -56°C to -2°C. This increase is due to absorption of solar radiation. This region is rich in ozone which absorbs harmful UV radiations of the sun and converts them into heat. In this way ultraviolet radiations are prevented to reach the earth. Ozone is formed from oxygen by a photochemical reaction. The ozone content of the stratosphere is more or less constant. Besides ozone, stratosphere also contains nitrogen, oxygen and small amount of water vapours. This region is free from turbulent conditions or changing weather pattern.
- (iii) Mesosphere: Next to stratosphere is the mesosphere which extends upto the height of 90 km. The lowest temperature of -92°C is observed in this region. This is due to low concentrations of ozone, oxygen and nitrogen present and thus possesses little capacity to absorb solar radiation.
- (iv) Thermosphere: This is the region above mesosphere and extends upto the height of 500 km. The temperature in this region rises from −92°C to 1200°C. This is due to the bombardment of molecular oxygen and nitrogen and atomic species by energetic particles, such as electrons and protons, from the sun. Thus, this is an electrically charged zone. Typical reactions in this zone are:

$$N_2 \longrightarrow 2N$$
  $\Delta H^\circ = 941.4 \text{ kJ}$   
 $N \longrightarrow N^+ + e^ \Delta H^\circ = 1400 \text{ kJ}$   
 $O_2 \longrightarrow O_2^+ + e^ \Delta H^\circ = 1176 \text{ kJ}$ 

The reverse of these processes liberates an equivalent amount of energy, mostly as heat. The temperature becomes about 1000°C near 400 km height. The ionised particles are responsible for the reflection of radiowaves on earth and enable wireless communication.

[The region between the altitudes of 50 km and 100 km is called **ionosphere**. In this region, there are high concentrations of ions like  $O_2^+$ ,  $O_2^+$ ,  $O_2^+$  and electrons.]

The region above the thermosphere which extends upto a height of 1600 km and merges with outerspace is called **exosphere.** It contains mainly atomic and ionic oxygen, hydrogen and helium.

# Chemical and Photochemical Reactions in Atmosphere

Many chemical and photochemical reactions are occuring in atmosphere in which main constituents such as oxygen, nitrogen, carbon dioxide, etc., are involved.

#### **Reactions Occurring in Troposphere**

The carbon dioxide and water present in atmosphere are used by green plants in the presence of sunlight to form glucose. The process is termed as photosynthesis. In this process chlorophyll (the green colouring material in plants) plays a role of a catalyst.

$$6\text{CO}_2 + 6\text{H}_2\text{O} \xrightarrow{hv} \text{Chlorophyll} C_6\text{H}_{12}\text{O}_6 + 6\text{O}_2$$

The process of photosynthesis can be represented by the following equations also:

$$CO_{2} + 4H^{+} + 4e^{-} \longrightarrow C_{2} + 4H^{+} + 4e^{-}$$

$$CO_{2} + 4H^{+} + 4e^{-} \longrightarrow [CH_{2}O] + H_{2}O$$

$$\downarrow$$

$$C_{6}H_{12}O_{6}$$

Photosynthesis releases oxygen to atmosphere.

In troposphere, oxygen takes part in energy producing reactions like burning of fossil fuels.

$$CH_4 + 2O_2 \longrightarrow CO_2 + 2H_2O + Energy$$
(Natural gas)

Oxygen is also utilised in the degradation of organic material by aerobic organisms.

Organic matter + 
$$O_2 \xrightarrow{\text{Aerobic} \atop \text{organisms}} CO_2 + H_2O$$

Chemical reactions such as hydrolysis, oxidation, etc., involving oxygen occur at the surface of the earth. Rusting of iron is one such example.

$$4\text{Fe} + 3\text{O}_2 \longrightarrow 2\text{Fe}_2\text{O}_3$$

Though nitrogen by itself is inert and unreactive, its presence in atmosphere is extremely important, since, it dilutes the harmful effects of pure oxygen (in pure oxygen most of the organic matter is burned). Electrical disturbances in the atmosphere initiates reactions between nitrogen and oxygen.

$$N_2 + O_2 \xrightarrow{h\nu} 2NO \xrightarrow{O_2} 2NO_2 + \xrightarrow{Rain} HNO_3$$

$$\xrightarrow{Alkaline}_{\substack{\text{substances} \\ \text{in soil}}} Nitrates$$

Free nitrogen is also converted into nitrates by nitrifying bacteria. This conversion is termed as nitrogen fixation. It can be represented as:

$$N_2 \xrightarrow{\text{Nitrogenase}} NH_3 \longrightarrow NO_2^- + \xrightarrow{\text{In soil}} NO_3^-$$

Nitrogen is returned to atmosphere by breaking down of nitrates in the soil in denitrification process by some soil microorganisms.

$$4NO_3^- + 2H_2O \longrightarrow 2N_2 + 5O_2 + 4OH^-$$

Some of the gaseous components of the atmosphere like water vapours, carbon dioxide, nitrous oxide and methane allow the solar radiation to pass through, but do not allow the terrestrial radiation to escape. This is what the glass does in a greenhouse. The gases absorb the heat energy reflected by earth's surface and re-emit part of it towards the surface and hence, the air near the surface becomes warmer and therefore, an increase in average temperature is observed. These gases are called greenhouse gases and the phenomenon as greenhouse effect. The concentration of these gases decreases with height, hence the greenhouse effect decreases, i.e., at this altitude the energy reflected by earth's surface is not retained by absorption and is transmitted to outer space. For this reason temperature within the troposphere decreases with increasing altitude. It drops to about -56°C by the time an altitude of 10-11 km is reached.

The concentration of the water vapours varies from place to place and from time to time at the same place. The global average of water vapours is about 1%, but it can be as high as 4%. The amount of water vapours over a given region also varies with height. About 90% of the atmospheric moisture lies below an altitude of 5 km. As the vapours are carried upwards, they cool, condense into cloud particles and return to the earth's surface by precipitation (rain or snow).

Another important constituent of troposphere is the aerosols or suspended particles. In urban and industrial areas, the concentration of aerosols may be high. These particles are mostly concentrated in the lower layers of troposphere. Suspended particles too influence the weather conditions. Most of them act as nuclei around which water vapours condense to form clouds. They also intercept and reflect insolation of sun. Dense haze and smog are also caused by the presence of suspended particles in the atmosphere.

#### **Reactions Occurring in Stratosphere**

The principal chemical species present in the stratosphere are  $N_2$ ,  $O_2$ ,  $O_3$  and some  $H_2O$ . The far ultraviolet radiation (wavelength < 190 nm) are filtered before these reach the stratosphere. Ultraviolet radiations (> 190 nm and < 340 nm) are removed in the stratosphere due to the following reactions, *i.e.*, these dangerous and harmful radiation to living species are prevented to reach earth's surface.

$$O_2 \xrightarrow{\text{UV}} O + O$$

The highly reactive O atoms combine with oxygen molecules to form ozone.

$$O + O_2 + M \longrightarrow O_3 + M$$
 (Exothermic reaction)

where M is some inert substance such as  $N_2$ . The role of M is to absorb some of the excess energy released and prevent the spontaneous decomposition of  $O_3$  molecule. The energy which is not absorbed by M is given off as heat. Ozone absorbs UV light between 200 and 300 nm.

$$O_3 \xrightarrow{UV} O + O_2$$

$$O_3 + O \longrightarrow 2O_2$$

Hence, a cycle of ozone formation and destruction exists. Thus, the stratosphere acts as a shield against UV radiations which can induce skin cancer, cause genetic mutations and destroy crops and other forms of vegetation at the earth's surface. The formation and destruction of ozone by the natural process is a dynamic equilibrium that maintains a concentration of ozone in the stratosphere. Infrared radiations to some extent are also absorbed and re-emitted by ozone. This is also responsible for temperature rise.

#### **Reactions Occurring in Upper Atmosphere**

In the upper atmosphere (*viz.*, mesosphere, thermosphere and ionosphere) ultraviolet radiations cause photochemical reactions giving rise to excited atoms, ions and electrons.

Some reactions are given below:

$$O_{2} + hv \xrightarrow{135-176 \text{ nm}} O + O$$
Oxygen atoms
$$O_{3} + hv \xrightarrow{308 \text{ nm}} O^{+}_{0xygen \text{ ion}} + O_{2} + e$$

$$O_{2} + hv \longrightarrow O_{2}^{+} + e$$

$$N_{2} + hv \longrightarrow N_{2}^{+} + e$$

$$NO + hv \longrightarrow NO^{+}_{0} + e$$

Free ions and electrons do not survive for long in the lower part of the mesosphere as the density is comparatively high. They collide with other species to form neutral species. In the upper part of atmosphere, these species survive for long as the density of the atmosphere is low.

The ultraviolet radiations are not available during night, so the ions recombine with free electrons to form neutral species.

**Importance of atmosphere:** The following are the main advantages of the atmosphere which the nature has provided to living species.

(a) The atmosphere sustains life on earth and saves it from the hostile environment of outer space. It absorbs most of the cosmic rays from outer space and major portion of the electromagnetic radiations from the sun. It is able to transmit only near ultraviolet-visible, near infrared radiation (300–2500 nm) and radio waves (0.10–40.0μ) while filtering out tissue-damaging radiation.

- (b) The atmosphere maintains the heat balance of the earth by absorbing infrared radiations emitted by the sun and re-emitted from the earth.
- (c) The atmosphere is a source of oxygen which is essential for life on earth. It is required for respiration and combustion.
- (d) The atmosphere provides carbon dioxide which is essential for plant photosynthesis—carbon dioxide acts like a greenhouse by trapping the heat.
- (e) The atmosphere supplies nitrogen. Nitrogen is fixed by bacteria and electrical disturbances. The nitrogen compounds, thus, formed are essential for growth of plants. Nitrogen inertness reduces the activity of oxygen.
- (f) The atmosphere serves as a storehouse for water vapours which leads to rainfall activity.
- (g) The atmosphere helps in maintaining various natural cycles such as nitrogen cycle, oxygen cycle, CO<sub>2</sub> cycle, etc.

#### 2. HYDROSPHERE

The total water present on the earth in solid, liquid and gaseous phases constitutes the **hydrosphere**. Water covers 71% of the total surface of the earth. Earth is sometimes called a **water planet**. Hydrosphere includes all types of water resources such as oceans, seas, rivers, lakes, streams, reservoirs, glaciers, polar ice caps and ground water (*i.e.*, water below earth's surface). Approximately 97.3% of the world's vast supply of water is in oceans. Polar ice caps and glaciers provide 2% water while underground fresh water is hardly 0.6%. Fresh water lakes and rivers account for less than 0.01% of the total, yet they nevertheless, contain enormous amount of water  $(1.26 \times 10^{14} \text{ m}^3)$ . In vapour form, water is present only to the extent of 0.001%.

Water is essential to all forms of life. A man, on an average, consumes about 2.2 litre of water daily. More than 70% of the human's body mass is made of water. Plants cannot survive without water. Water is required for domestic uses, industrial cooling, power generation, transportation and waste disposal besides for drinking and agriculture (irrigation). The conservation and keeping up of a good supply of water is, thus, very essential.

**Sea water** is unfit for drinking or agriculture because each kilogram contains 35 g of dissolved salts. Most of the dissolved salts in sea water is sodium chloride, but more than 60 different elements are present in small amounts.

Sea water contains a number of dissolved gases, principally nitrogen, oxygen, carbon dioxide and noble gases. Nitrogen and noble gases are not utilised in any biological process. However, oxygen and carbon dioxide play important roles in marine environment. The sea plants photosynthesise and respire both. This process only occurs near the sea surface. The oxygen content decreases with depth. A minima occurs in the 200–1000 m depth range. Dissolved phosphates and nitrates act as fertilizers for **phytoplanktons** and other marine plants.

Snow and ice represent both a valuable asset and a menacing hazard. Snow is the principal source of water, not only in many of the world's mountainous areas, but also in the densely settled plains and valleys. Moreover, in the critical dry years, snow and ice are more dependable than other sources of water. The most detrimental effect of snowfall lies in the disruption of communication systems. Glaciers cause rock erosion also. In recent times, the ice caps of polar regions and glaciers have been greatly affected on account of the global warming.

Water for use in homes, agriculture and industry is generally obtained from lakes, rivers or underground sources. The water which we use for drinking purposes must be first purified to remove solid particles, colloidal particles, bacteria and other harmful impurities. Important steps for purification include preliminary filtration, sedimentation, sand filtration, aeration and sterilisation. The purified water still contains upto 0.5 g/L of inorganic ions such as Na<sup>+</sup>, K<sup>+</sup>, Mg<sup>2+</sup>, Ca<sup>2+</sup>, Cl<sup>-</sup>, SO<sup>2+</sup>, F and HCO<sup>3</sup> but in such low concentrations these ions are not harmful. The circulation of water between hydrosphere, atmosphere, lithosphere and biosphere is called the **hydrological cycle**.

Water is an excellent solvent for many of the chemicals that make up our bodies, as well as for a wide variety of other substances. The importance of water as a slovent in living organisms and in the environment is given in the following points:

- (i) Blood plasma is an aqueous solution containing a variety of life-supporting substances. Inhaled oxygen dissolves in blood plasma in the lungs where O<sub>2</sub> combines with haemoglobin. Blood carries dissolved CO<sub>2</sub> to lungs to be exhaled from the body.
- (ii) Water transports nutrients into all cells and organs of our body.
- (iii) Water helps to maintain a chemical balance in the body by flushing waste products out.
- (iv) By dilution, water reduces the concentration of pollutants to safe levels or by carrying them away.
- (v) Plants take up nutrients from soil with the help of water. Water transports these materials into various parts of the plant.
- (vi) Rain water carries substances from atmosphere down to earth.

#### 3. LITHOSPHERE

It is the solid component of the earth consisting of soil, rocks, mountains, etc. It is the region which interacts with hydrosphere, atmosphere and biosphere. The earth comprises of three layers, *viz.*, **crust, mantle** and **outer** and **inner core.** The outermost solid portion, which is about 8–40 km above the mantle, is known as **crust.** The surface of the earth is covered with soil. It is the most important part of the lithosphere from the point of view of environment. Soil contains weathered

rocks as well as organic matter. It is a storehouse of minerals and is used for growing plants. The top layer is vital component since all the nutrients required by plants are present in this layer. A healthy soil always consists of micro-organisms such as bacteria, fungi, algae, protozoa, worms, etc. The top layer of the soil is actually the feeding zone of plants. Thus, the soil erosion must be avoided to maintain the fertility of the soil.

#### 4. BIOSPHERE

It refers to that part of the earth in which all life forms exist. Biosphere represents an interface between the non-living and the living. Biosphere extends from approximately 6 km above the sea level to about 10 km below the sea level. Living organisms and their non-living environment are inseparably interrelated and interact upon each other in an orderly manner so that there is continuous flow of energy and matter between them. Biosphere is equipped with certain special conditions which are necessary to support life. These conditions are:

- (i) A supply of air and water is available.
- (ii) A suitable temperature range exists.
- (iii) An area where the interface between lithosphere, atmosphere and hydrosphere exists is available.
- (iv) A supply of usable energy is available.
- (v) A supply of nutrients is available.

A community of organisms interacting with each other and with their non-living surroundings is called an ecosystem. Ecosystem may be small or large (Aquarium—small and tropical forest—large ecosystem.) Each ecosystem has its two parts: living and non-living, i.e., biotic and abiotic. Human activities can enhance the life supporting characteristics of the ecosystem or can degrade them as well.

Energy for the biosphere is provided through the action of photosynthesis. In this process, green plants use solar energy extract CO<sub>2</sub> and H<sub>2</sub>O from atmosphere and convert them into carbohydrates. The carbon is then said to be fixed by plants. The energy stored in the fixed carbon flows through the biotic community.

The elements needed by living organisms are of two types:

- (i) Macronutrients and (ii) Micronutrients.
- (i) Macronutrients: These elements are required in substantial quantities by living organisms. These elements are H, C, O, N, Ca, K, Si, Mg, S, P and Na. Carbon, hydrogen and oxygen are the main constituents of organic living matter. Nitrogen is contained in amino acids and proteins. Phosphorus, calcium and silicon are required for skeletal structure of vertebrates. Sodium and potassium play a role in regulating osmotic pressure in living cells. Magnesium is an essential constituent of chlorophyll and enzymes. Sulphur is the constituent of some of the essential amino acids.
- (ii) Micronutrients: These elements are required by living organisms in smaller quantities. These elements, however, are as vital as macronutrients. These are also called **tracer**

**elements.** Examples of tracer elements are: Al, Cl, Fe, Mn, Mo, etc. These elements play a specialised role in biochemical reactions such as photosynthesis and metabolism.

For terrestrial ecosystems, soil serves as a medium of entry of the nutrients into living organisms. Plants absorb their nutrients from the soil through their roots. With these they synthesise essential biomolecules upon which they, as well as other living species, depend.

**Biogeochemical cycles:** In order to maintain the biosphere and thus life, chemical elements must be recycled so that after use they become available again. A number of **biogeochemical cycles** or **natural cyclic processes** are taking place in the environment which keep a balance of the different materials present in the environment.

A biogeochemical cycle or natural cyclic process is defined as a process in which a material of the environment is consumed in some ways and then reproduced in other ways so that a balance of that material is maintained in the environment.

The following biogeochemical cycles are occurring in the environment.

- (i) Water cycle
- (ii) Carbon cycle
- (iii) Nitrogen cycle
- (iv) Oxygen cycle
- (v) Phosphorus cycle
- (v) Sulphur cycle, etc.

# 19:3 ENVIRONMENTAL POLLUTION AND ENVIRONMENTAL POLLUTANTS

The term environment as far as pollution is concerned, includes the air, the water and the land (soil). The pollution of our environment is one of the biggest hazards that humanity faces today. Pollution is a gift of industrial civilization. Progress in agriculture and industry have resulted into unlimited exploitation of every bit of natural resource. Such activities of man have adverse effect on all forms of living organisms in the biosphere. The unfavourable conditions created by man himself has threatened the survival not only of man himself but also of other living organisms. For the smooth growth and development of all living organisms, a balanced or natural environment is required which has been provided by nature. In balanced environment, the various components are present in a definite ratio and proportion. When the ratio of one or more components of the balanced environment is disturbed by natural happenings or human activities, it is said that the environment has been polluted.

Thus, any undesirable change of the physical, chemical or biological characteristics in the air, water and land which is harmful to man directly or indirectly through his animals, plants, industrial units or raw materials is termed environmental pollution.

Pollution may be natural or man-made (artificial).

(i) Natural pollution: It originates from natural processes. A few examples of natural sources of pollution are:

- (a) Volcanic eruptions; (b) Forest fires and coal mines fire; (c) Bacterial decomposition of agricultural matter; (d) Pollen grains of flowers; (e) Excreta of animals; (f) Floods; (g) Radioactive substances.
- (ii) Artificial pollution: It originates from the activities of man. Environmental deterioration by man is attributable to three major factors: (i) over-population (ii) urbanisation and (iii) industrialisation. The increasing amount of wastes generated by these three phenomena undoubtedly degrades the quality of land, air, water and food. When the waste products are not efficiently assimilated or decomposed or otherwise removed by the natural, biological and physical processes of the biosphere, adverse effects may result as the materials responsible for pollution accumulate or are converted to more toxic substances. Anything, if present in the environment in excess of permissible limits, causes pollution. The problem of pollution is very complex as one type of pollution will disturb and cause pollution in other systems also.

#### Pollution, thus, means:

- (i) The presence of anything in the environment in excess of required amount.
- (ii) Anything put into the environment which was not there in its natural state.
- (iii) Direct or indirect changes in one or more components of the ecosystem which are harmful to living organisms.
- (iv) Intentional or unintentional release of any chemical or geochemical substance in the environment with adverse, harmful or unpleasant effects.

Today everything is polluted. The air we breathe is polluted by automobile exhausts, industries, thermal power plants, etc. The fruits and vegetables are polluted due to the use of pesticides and insecticides and water in lakes and rivers has been polluted by wastes from chemical and other factories, by sewage due to uncontrolled population and use of plastic materials.

Although pollution is as old as man himself, but his awareness about it is only very recent. Concern over the state of environment has grown over since the sixties. The catastrophic events like the Bhopal gas tragedy, the Chernobyl nuclear reactor breakdown, etc., have given us a warning about the dangers of pollution. It is, thus, the duty of every citizen, every nation and every government to take concrete steps to minimise and control pollution.

#### **Pollutants**

Pollutants are chemical, biological or physical agents that exert undesirable effects on living organisms including human health, environment or belongings. According to "The Indian environment (Protection) Act 1986", a pollutant has been defined as any solid, liquid or gaseous substance present in such concentration as may be or may tend to be injurious to the environment. In a very simple way, a pollutant can be defined as a substance or an agent which causes pollution.

Various types of pollutants are listed below:

(i) Chemical agents:

Gases and particulates; Heavy metals; Pesticides; Petroleum; Solid and liquid wastes

(ii) Physical agents:

Heat; Odour; Noise; Radiation

(iii) Biological agents:

Micro-organisms; Population

Odum, in 1971, gave a different classification of pollutants. He divided them into two basic types from an ecosystem point of view.

- (a) Non-degradable pollutants: These are poisons like mercuric salts, aluminium cans, lead compounds, long chain phenolic chemicals, pesticides, etc. which either do not degrade or degrade very slowly in the ecosystem naturally. These are not recycled in natural environment. These substances are harmful even in low concentrations.
- **(b) Bio-degradable pollutants:** These are domestic wastes which can be rapidly decomposed under natural processes by micro-organisms. However, when accumulation of these occurs, *i.e.*, complete degradation does not take place, then these pollute the biosphere and create problems.

The various principal environmental pollutants are:

- (i) Deposited matter-Soot, smoke, tar, dust, grit, etc.
- (ii) Gases-Oxides of nitrogen (NO, NO<sub>2</sub>), sulphur dioxide (SO<sub>2</sub>), carbon monoxide, halogens, etc.
- (iii) Fluorides
- (iv) Acid droplets-Sulphuric acid (H<sub>2</sub>SO<sub>4</sub>), nitric acid (HNO<sub>3</sub>), etc.
- (v) Metals-Mercury, lead, iron, chromium, zinc, cadmium, nickel, tin, etc.
- (vi) Agrochemicals-Pesticides, herbicides, fungicides, bactericides, insecticides, weedicides and fertilizers, etc.
- (vii) Photochemical oxidants-Peroxyacetyl nitrate (PAN), peroxybenzoyl nitrate (PBN), aldehydes, ethylene, ozone, photochemical smog, etc.
- (viii) Petroleum and complex organic compounds.
- (ix) Sewage due to uncontrolled population and faulty urban planning.
- (x) Radioactive waste.
- (xi) Noise and heat.

# 19.4 SOME COMMONLY USED TERMS IN ENVIRONMENTAL POLLUTION

1. Contaminant: A substance which does not exist in nature but is introduced by human activity into the environment is called contaminant. It may or may not be harmful to the living organisms or non-living materials. The contaminant becomes pollutant when it has harmful effect. For example, methyl isocyanate vapours leaked from a defective tank killed many persons and caused respiratory, lung, eye and throat problems to others in Bhopal can be called contaminant, as it does not occur in atmosphere but it can be termed pollutant also as it

has dangerous effects. Generally, highly toxic materials are considered as pollutants.

- **2. Source:** The site from which the pollutants or contaminants originates is called source. The knowledge about the source is important because it helps to devise the methods to eliminate or minimise the pollutant.
- **3. Sink:** The material or medium which removes or interacts with a long lived pollutant is called sink. For example, oceans act as sink for atmospheric carbon dioxide and other water soluble gases. Limestone minerals act as sink for oxides of sulphur and sulphuric acid (acid rain).

$$\begin{array}{c} \text{CaCO}_3 + \text{SO}_2 \longrightarrow \text{CaSO}_3 + \text{CO}_2 \\ \text{CaCO}_3 + \text{SO}_3 \longrightarrow \text{CaSO}_4 + \text{CO}_2 \\ \text{CaCO}_3 + \text{H}_2\text{SO}_4 \longrightarrow \text{CaSO}_4 + \text{CO}_2 + \text{H}_2\text{O} \end{array}$$

- **4. Receptor:** Anything that is affected or spoiled by pollutants is called receptor. For example, marble structures are receptors of acid rain. Human beings are receptors of photochemical smog which causes irritation in the eyes and brings breathing problems.
- 5. Threshold Limit Value (TLV): The permissible limit of a pollutant in the atmosphere to which if a healthy person is exposed for 8 hours a day or 40 hours a week for life time, there is no adverse effect on him, is called threshold limit value. For example, TLV of CO is 40 ppm while that of CO<sub>2</sub> is 5000 ppm.

### 195 TYPES OF POLLUTION

The usual practice to classify pollution is on the basis of medium or component of the environment polluted. The common types of pollution are:

- 1. Air pollution
- 2. Water pollution
- 3. Soil or Land pollution

Sometimes, the classification is done according to the type of pollutant by which the pollution has been caused. The following types of pollution have been observed on this basis:

- (i) Air pollution
- (ii) Water pollution
- (iii) Soil pollution
- (iv) Noise pollution
- (v) Thermal pollution
- (vi) Radiation pollution
- (vii) Marine pollution
- (viii) Solid waste pollution
- (ix) Industrial pollution
- (x) Plastic pollution
- (xi) Oil pollution
- (xii) Soap and detergent pollution
- (xiii) Metal toxicity pollution
- (xiv) Smog pollution

In this unit, we shall study the first three types of pollution.

- (i) Air pollution
- (ii) Water pollution and
- (iii) Soil pollution

It is usually difficult sometimes to specify that a particular agent is an air pollutant, or a water pollutant or a soil pollutant. For example, a pesticide when sprayed might partly contaminate the air in vapour form, soil by adsorption and water running through a sprayed field.

### 19.6 AIR POLLUTION

Air is one of the most important constituents of man's environment. It has been calculated that a man breathes about 22,000 times a day inhaling about 16 kg of air by mass. Air is present everywhere. Air is essentially a mixture of gases. Due to the activity of living organisms, different gases in the atmosphere are found in a definite ratio and proportion. There is cycling of gases between the living organisms and atmosphere. It is due to organisms that oxygen and carbon dioxide are found in a balanced state in the atmosphere. Atmosphere maintains a narrow difference of day and night temperatures. It acts as a shield around the earth against lethal UV radiation and meteors. Without atmosphere, there will be no lightning, no wind, no clouds, no rains, no snow and no fire.

Air is the foremost susceptible component of our environment prone to pollution. Man has disturbed the favourable and natural air atmosphere in different ways, by removal of plants, by development of various industrial establishments, by burning of fossil fuels, etc. Pollution of air may have profound health effects and other consequences.

The composition of pure dry air has been given in section 19.2. Air pollution occurs when the concentration of a particular component of the air crosses the threshold limit value and becomes harmful.

Air pollution may be defined as any atmospheric condition in which certain substances are present in such concentrations that they can produce undesirable effects on man and his environment. According to WHO, air pollution may be defined as follows: "Substance put into air by the activity of mankind in a concentration sufficient to cause harmful effect to his health, vegetables, property or to interfere with the enjoyment of his property".

The study of air/atmospheric pollution mainly consists of the study of the two lower parts of atmosphere, *i.e.*, upto a height of about 50 km above the surface of the earth.

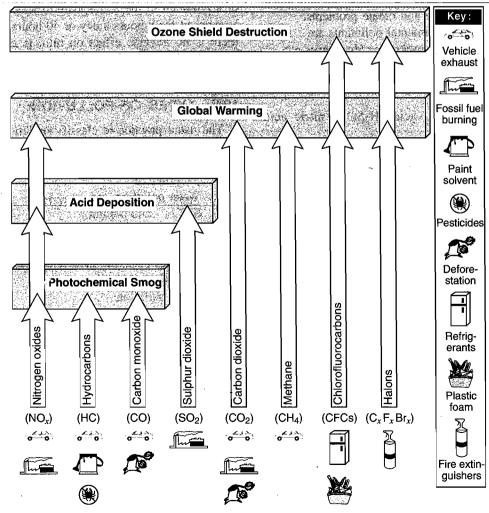

Fig. 19.1 Sources of air pollution and effects of air pollution

- 1. Tropospheric pollution
- 2. Stratospheric pollution

**Tropospheric pollution** is much more wide spread. The main pollutants of this sphere are gases such as oxides of nitrogen, oxides of sulphur, oxides of carbon, hydrogen sulphide, hydrocarbons, etc., and particulated matter such as dust, smoke, mist, fumes, aerosols, etc. Most of these substances are naturally present in definite proportions and are usually considered to be harmless but when their concentrations cross the threshold value limit, they become pollutants.

**Stratospheric pollution** is mainly due to depletion of ozone layer which may affect plants and human life adversely as UV radiations reach the earth.

#### Sources of air pollutants

There are two main sources of air pollution.

- **1. Natural sources :** The natural sources of air pollution are:
- (a) Volcanic eruptions emitting poisonous gases such as CO, SO<sub>2</sub>, H<sub>2</sub>S, etc.
- (b) Forest fires (caused by lightning)
- (c) Pollen grains dispersal
- (d) Bacterial decomposition of organic matter
- (e) Wind erosion of soil
- (f) Natural radioactivity, etc.
- 2. Man-made sources, i.e., sources due to human activities :

The human activities responsible for air pollution are summarised as:

- (a) Burning of fossil fuels such as coal, wood, etc.
- (b) Combustion of gasoline in the automobiles
- (c) Deforestation
- (d) Overpopulation
- (e) Fast industrialisation
- (f) Agriculture activities
- (g) Nuclear explosion, etc.

#### Air Pollutants

Air pollutants are classified into two types:

- 1. Primary pollutants
- 2. Secondary pollutants
- 1. Primary pollutants: These are harmful chemical substances which enter directly into the atmosphere as a result of natural and human activities. These include inorganic gases such as sulphur dioxide, carbon monoxide, hydrogen sulphide, nitric oxide, carbon dioxide, ammonia, hydrogen fluoride, etc., hydrocarbons and radioactive substances, particulate matter such as ash, dust, smoke, fumes, aerosols, etc.
- **2. Secondary pollutants:** These are harmful chemical substances which are formed by chemical interactions among primary pollutants and normal atmospheric constituents. For example, sulphur dioxide is a primary pollutant. It reacts with

oxygen in the atmosphere to form sulphur trioxide which further reacts with water vapours to form sulphuric acid.

$$2SO_2 + O_2 \longrightarrow 2SO_3$$

$$SO_3 + H_2O \longrightarrow H_2SO_4$$

Thus, sulphur trioxide and sulphuric acid are secondary pollutants.

The common secondary pollutants are:

NO<sub>2</sub>, HNO<sub>3</sub>, O<sub>3</sub>, H<sub>2</sub>O<sub>2</sub>, aldehydes, ketones, various nitrates and sulphates formed in soil, etc. The major processes that convert the pollutants from their primary forms to secondary forms are oxidation, dissociation and dissolution.

Reaction	Primary pollutant	Secondary pollutant
Oxidation	Sulphur dioxide	Sulphur trioxide
	Carbon monoxide	Carbon dioxide
	Hydrogen sulphide	Sulphur dioxide
Dissociation	Nitrogen dioxide	Nitric oxide + oxygen
	Oxygen (molecular)	Oxygen (atomic)
	Hydrocarbons and aldehydes	Organic radicals
Dissolution	Carbon dioxide	Carbonic acid
	Sulphur trioxide	Sulphuric acid
	Nitrogen dioxide	Nitric/Nitrous acid

#### Major Air Pollutants of Tropospheric Pollution

More than 90% of the air pollution (tropospheric pollution) is caused by the following five major pollutants.

- 1. Carbon monoxide (CO)
- 2. Oxides of sulphur  $(SO_X)$
- 3. Oxides of nitrogen (NO<sub>x</sub>)
- 4. Hydrocarbons  $(C_XH_Y)$
- 5. Particulates

Each of these pollutants is discussed one by one with respect to its sources, its harmful effects and methods to control it.

#### 1. Carbon monoxide (CO)

Carbon monoxide (CO) is a colourless, tasteless and odourless gas. It is 96.5% as heavy as air and is not appreciably soluble in water. It constitutes the single largest pollutant in urban atmosphere. It is highly toxic as it has a strong affinity towards haemoglobin of the blood and renders it ineffective in blood streams for oxygen supply. The gas is fatal over 1000 ppm, causing unconsciousness in an hour and death in four hours. If the gas is inhaled for few hours at even a low concentration of 200 ppm, it causes symptoms of poisoning. The accepted maximum allowable concentration (MAC) for occupational exposure is 50 ppm for 8 hours.

Carbon monoxide is generated by natural sources and man-made sources. Natural processes produce a larger amount of carbon monoxide than man-made processes.

- (a) Natural sources: The chief natural processes which contribute CO to atmosphere are:
  - (i) Volcanic eruptions
  - (ii) Forest fires

- (iii) Methane (an important and major constituent of natural gas and produced by bacterial decay of living or organic matter) on oxidation under controlled conditions gives CO
- (iv) Decomposition or degradation of chlorophyll.
- (v) The surface waters of western Atlantic ocean have been found to be supersaturated with CO. This is given to atmosphere. The production of CO in the ocean is biological. Marine algae and marine siphonophore produce carbon monoxide.
- (b) Man-made sources: The main sources are:
- (i) Incomplete combustion of fuels containing carbon: Approximately 80% CO comes from automobiles. In urban areas, it is observed that there is relatively high concentration of CO during peak hours. It has been estimated that for every litre of petrol by automobile about 370 g carbon monoxide is released as vehicular exhaust. The consumption of petroleum products and the number of automobiles are increasing at an alarming pace; thus CO levels will also increase and making the atmosphere as health hazard. Various forms of indoor combustion devices such as stoves, furnaces, gas fired heaters and charcoal braziers emit carbon monoxide.
- (ii) Carbon monoxide is ejected from waste disposal combustion, coal mines and power plants.
- (iii) Cigarette smoke contains about 2% carbon monoxide due to incomplete combustion of tabacco.
- (iv) Carbon monoxide is generated during several operations in iron and steel industry. Carbon monoxide is also a constituent of several industrial gases. For example, coal gas contains 5–10% CO and water gas contains 30–40% CO.
- (v) Agricultural waste burning contribute a considerable amount of carbon monoxide.

**Sinks of carbon monoxide:** Though natural processes and human activities are releasing large amounts of carbon monoxide in atmosphere, yet the level of CO in air does not rise too much. This is due to the presence of some natural sinks.

(i) Soil acts as an important **sink** for carbon monoxide. A number of soil bacteria such as *Methanosarcina barkerii* and *Methanobacterium formicum* are known to remove carbon monoxide. In the presence of these bacteria CO is either oxidised or converted into methane.

$$2CO + O_2 \xrightarrow{Soil} 2CO_2$$

$$CO + 3H_2 \xrightarrow{Soil} CH_4 + H_2O$$

**Note:** Urban areas face a greater threat of CO poisoning as the soil is covered by concrete and buildings and soil bacteria is not effective.

(ii) Some of the species such as hydroxyl (OH), perhydroxyl (HOO) radicals, atomic oxygen, ozone, nitrogen dioxide, etc., which exist in atmosphere can oxidise CO into CO<sub>2</sub>.

$$\begin{array}{c} \text{CO} + \overset{\bullet}{\text{OH}} & \longrightarrow \text{CO}_2 + \overset{\bullet}{\text{H}} \\ \text{CO} + \text{O} & \longrightarrow \text{CO}_2 \\ \text{CO} + \text{O}_3 & \longrightarrow \text{CO}_2 + \text{O}_2 \end{array}$$

(iii) The carbon monoxide may be transported from troposphere to stratosphere where it is readily oxidised into carbon dioxide by atomic oxygen, ozone, etc.

**Harmful effects of CO:** During breathing, the haemoglobin (Hb) present in the red blood cells combines with oxygen reversibly to form oxyhaemoglobin.

$$Hb + O_2 \longrightarrow HbO_2$$

The oxyhaemoglobin travels to the different parts of the body through arteries where it gives up oxygen and takes up CO<sub>2</sub> for return to the lungs where it is exhaled.

In case, the air which we breathe contains CO, it combines readily with haemoglobin (CO has 200 times more affinity than oxygen for haemoglobin). Due to formation of carboxy-haemoglobin (HbCO), the quantity of oxygen available to the body cells gets reduced, *i.e.*, carbon monoxide reduces the oxygen carrying capacity of the blood and this leads to oxygen starvation (anoxia). The deficiency of oxygen produces headache, drowsiness, choking, cardiac and pulmonary complications leading to paralysis and death.

- [(i) Smokers are more prone to anoxia. Pregnant women are advised not to smoke as increased CO level is injurious for unborn child.
- (ii) It is dangerous to sleep in a closed room with a coke fire burning inside during winter night.
- (iii) In case, carbon monoxide poisoning is detected well in time, the person can be treated by exposing him to oxygen under pressure (2-2.5 atm). Carbon monoxide of the carboxyhaemoglobin is replaced by oxygen and the victim may be revived.

$$HbCO + O_2 \longrightarrow HbO_2 + CO$$

Carbon monoxide has harmful effects on plants also when exposed for sufficient time. It reduces the nitrogen fixing ability of the bacteria. It also affects leaf drop, leaf curling, decrease in leaf size and premature ageing of the plants.

#### Control of Carbon Monoxide Pollution

The internal combustion engines in the automobiles are the primary sources of carbon monoxide emission. The engines emit a mixture of gases consisting of carbon monoxide, oxides of nitrogen, hydrocarbons and particulates. It is observed that if a particular method is used to control any one of these pollutants, than it results in the increase of other pollutants. For example, when air-fuel ratio (wt/wt) is 16:1, the emission of carbon monoxide and hydrocarbons is reduced but the emission of oxides of nitrogen increases. Thus, to minimize the emission of CO, suitable modifications are needed in the internal combustion engine or in the quality of the fuel. A few of these modifications proposed are as follows:

- (i) The carburettor is adjusted as to ensure proper air-fuel ratio. The presence of excess of air makes complete combustion of the fuel.
- (ii) Exhaust system is equipped with catalytic convertor which converts carbon monoxide into harmless products. Lead free gasoline is preferred these days as the catalyst gets easily poisoned by lead.
- (iii) Fuels such as CNG (condensed natural gas) and LNG (liquefied natural gas) which release minimum quantities of pollutants on combustion are advised to be used in place of gasoline.

#### 2. Oxides of sulphur (SOx)

Two common oxides of sulphur represented by the formula  $SO_X$  are sulphur dioxides ( $SO_2$ ) and sulphur trioxide ( $SO_3$ ). These are the most serious gaseous pollutants of the atmosphere. Both are colourless gases with pungent odour.  $SO_2$  is a primary pollutant while  $SO_3$  is a secondary pollutant:

**Sources:** 67% of the total amount of  $SO_2$  present in the atmosphere is released by **volcanic eruptions** (natural source) and remaining 33% is discharged due to human activity. The **man-made** sources of  $SO_2$  are:

(a) Coal combustion is the predominant man-made source of  $SO_2$  as its contribution is 60%. Coal contains 0.1 to 6% of sulphur. On combustion, this sulphur is oxidised to sulphur dioxide.

$$S + O_2 \longrightarrow SO_2$$

Coal is used in vast quantities in power plants and hence, power plants are largely responsible for release of  $SO_2$  into atmosphere.

- (b) Another contributor of sulphur dioxide is the combustion of petroleum and its products (20%).
- (c) It is also produced when sulphide ores like pyrites (FeS<sub>2</sub>), copper pyrites (CuFeS<sub>2</sub>), zinc blende (ZnS), galena (PbS), copper glance (Cu<sub>2</sub>S), etc., are roasted in air during extraction of respective metals.

$$2FeS2 + 5O2 \longrightarrow 2FeO + 4SO2$$

$$3Cu2S + 3O2 \longrightarrow 6Cu + 3SO2$$

$$2ZnS + 3O2 \longrightarrow 2ZnO + 2SO2$$

$$2PbS + 3O2 \longrightarrow 2PbO + 2SO2$$

(d) Hydrogen sulphide which is discharged into the air by natural processes is converted into SO<sub>2</sub> by oxidation in the atmosphere.

$$2H_2S + 3O_2 \longrightarrow 2H_2O + 2SO_2$$
  
 $H_2S + O_3 \longrightarrow H_2O + SO_2$ 

- (e) Many industries such as paper making, sulphuric acid manufacture, petroleum refining, etc., release SO<sub>2</sub> into atmosphere.
- (f) The sulphur dioxide persists in atmosphere for 2–4 days. During this time it is either dispersed to far away locations or oxidised to sulphur trioxide. The oxidation of sulphur dioxide can occur both photochemically or non-photochemically. In

the near ultraviolet region, the excited SO<sub>2</sub> molecules react with ozone (photochemical).

$$SO_2 + O_3 \xrightarrow{hv} SO_3 + O_2$$

Similarly, excited SO<sub>2</sub> molecules react with molecular oxygen.

$$2SO_2 + O_2 \xrightarrow{hv} 2SO_3$$

Non-photochemically, sulphur dioxide may be oxidised by molecular oxygen in presence of dust and soot particles.

$$2SO_2 + O_2 \xrightarrow{Particulates} 2SO_3$$

SO<sub>3</sub> immediately combines with moisture in atmosphere to form sulphuric acid.

$$SO_3 + H_2O \longrightarrow H_2SO_4$$
 (Sulphuric acid)

The sulphuric acid formed comes down to the earth as acid rain.

Sinks of oxides of sulphur:  $SO_2$  is moderatory soluble in water forming a weak acid solution.

$$SO_2 + H_2O \longrightarrow H_2SO_3$$
 (Sulphurous acid)

Oxides of sulphur are also converted into  $H_2SO_4$  (sulphuric acid). Both the acids in the form of acid rain come down on the earth where they meet with alkaline substances especially limestone minerals and sulphates are formed. In this way oxides of sulphur are removed from the atmosphere.

$$CaCO_3 + H_2SO_4 \longrightarrow CaSO_4 + H_2O + CO_2$$
  
 $CaCO_3 + H_2SO_4 \longrightarrow CaSO_3 + H_2O + CO_2$ 

Thus, limestone minerals act as sink for oxides of sulphur. Harmful effects of oxides of sulphur: (i) Both SO<sub>2</sub> and SO<sub>3</sub> are highly irritating gases to respiratory tract of human beings and animals. Even at low concentration (about 5 ppm), it causes drying of mouth, throat and eye irritation. It brings breathlessness and affects larynx (voice box). Higher concentrations of SO<sub>2</sub> may cause lung disease and even lung cancer. SO<sub>3</sub> is more harmful than SO<sub>2</sub>.

- (ii) Sulphur dioxide has a very damaging effect on plants even at very low concentration (0.03 ppm). It affects plant growth and nutrient quality of plant products. Plants exposed to  $SO_2$  for sufficient time suffer from **Chlorosis** disease, *i.e.*, bleaching or yellowish of green portions of the leaves.
- (iii) The oxides of sulphur as such or in the form of acids (sulphuric acid and sulphurous acid) affect or damage a number of materials. For example,
- (a) Building materials such as limestone, marble, slate, etc., are damaged due to following reaction.

$$CaCO_3 + H_2SO_4 \longrightarrow CaSO_4 + H_2O + CO_2$$

- (b) Metals, particularly iron, are corroded.
- (c) Fading and deterioration of fabric, leather, paper and paints occur in the atmosphere having oxides of sulphur.

Control of  $SO_2$  pollution: The following methods can be applied to control  $SO_2$  pollution.

(i) By use of low sulphur content fuels such as natural gas or sulphur free fuels: A number of steps are being

taken to make coal sulphur free before it is put to combustion. The combined sulphur such as iron pyrites is removed by subjecting grounded coal to hydraulic washing. Iron pyrites, being heavier settle down while coal from pyrites floats on the surface and is collected. The free sulphur is removed by passing hydrogen gas over the fuel in presence of catalyst. The sulphur is converted into  $H_2S$  which is absorbed in a solution of diethanolamine.

(ii) By removal of oxides of sulphur from flue gases: The oxides of sulphur can be removed from flue gases by use of chemical scrubbers. The flue gases are passed through the scrubber containing slurry of limestone or lime.

$$\begin{array}{c} \text{CaCO}_3 + \text{SO}_2 \longrightarrow \text{CaSO}_3 + \text{CO}_2 \\ \text{CaCO}_3 + \text{SO}_3 \longrightarrow \text{CaSO}_4 + \text{CO}_2 \\ \hline \text{Ca(OH)}_2 + \text{SO}_2 \longrightarrow \text{CaSO}_3 + \text{H}_2\text{O} \end{array}$$

SO<sub>2</sub> can also be removed by the use of a solution containing citrate ions.

$$SO_2 + H_2O \Longrightarrow HSO_3 + H^+$$
  
 $HSO_3 + H_2Cit^- \Longrightarrow [HSO_3 \cdot H_2Cit]^{2+}$   
 $Complex$ 

Citrate ions are regenerated by use of H<sub>2</sub>S gas. Pure sulphur is obtained as a byproduct.

(iii) By using alternate sources of energy such as hydroelectric power plants and nuclear power plants instead of thermal power plants.

#### 3. Oxides of nitrogen (NO<sub>x</sub>)

Nitrogen forms a number of oxides, viz., nitrous oxide  $(N_2O)$ , nitric oxide (NO), nitrogen dioxide  $(NO_2)$ , dinitrogen trioxide  $(N_2O_3)$  and dinitrogen pentoxide  $(N_2O_5)$ . However, from the point of view of atmospheric pollution, the first three are important which are found in significant amounts in atmosphere. The normal global concentration of nitrogen oxides should be  $3 \times 10^{-3}$  ppm but the concentration in some cities is found as high as 2 ppm. Major sources of oxides of nitrogen in the atmosphere are as follows:

**Natural sources:** (i) Nitrogen comprises about 78% by volume of the atmosphere and oxygen as 20%. The two gases do not react with each other unless the temperature is very high. During thunderstorm and lightning, nitrogen and oxygen combine to form nitric oxide, which is further oxidised to nitrogen dioxide.

$$N_2 + O_2 \xrightarrow{\text{Electric}} 2NO$$
  
 $2NO + O_2 \longrightarrow 2NO_2$ 

- (ii) The oxides of nitrogen in atmosphere come from bacterial decay of organic matter by soil micro-organisms on the surface of the earth.
- (iii) Nitrous oxide is formed by the action of aerobic and anaerobic bacteria in the soil on nitrogen based fertilizers.

Man-made sources: (i) Combustion of fossil fuels such as coal, oil, natural gas, gasoline, etc., in automobiles and

power plants produces high temperatures at which nitrogen and oxygen combine to form nitric oxide and nitrogen dioxide.

(ii) Chemical industries involving manufacture of H<sub>2</sub>SO<sub>4</sub>, HNO<sub>3</sub>, produce oxides of nitrogen as byproducts which are released into atmosphere.

#### Harmful Effects of Oxides of Nitrogen

(i) Nitric oxide is biologically less active and less toxic than nitrogen dioxide. It does not have harmful effects on human beings and animals. However, it is readily converted into nitrogen dioxide by atmospheric oxygen. NO<sub>2</sub> is extremely toxic to living tissues. It can cause irritation in eyes, nose and throat. The oxides of nitrogen can cause viral infections. Higher doses of NO<sub>2</sub> are responsible for bronchitis and respiratory problems.

Like CO, NO combines with haemoglobin and reduces its oxygen transport efficiency.

- (ii) The oxides of nitrogen suppress the growth of plants and damage leaf tissues. Higher concentrations of NO (10 ppm) can cause decrease in photosynthesis.
- (iii) Sunlight decomposes NO<sub>2</sub> into NO and active oxygen atoms.

$$NO_2 \xrightarrow{Sunlight} NO + O$$

Active oxygen atoms react with traces of hydrocarbons present in the atmosphere and produce materials which are responsible for **photochemical smog.** The smog is a health hazard.

(iv) NO<sub>2</sub> combines with atmospheric moisture to form a mixture of nitric and nitrous acids.

$$2NO_2 + H_2O \longrightarrow HNO_3 + HNO_2$$

These acids are carried to earth as acid rain. Acid rain reduces pH of the soil and thus reduces its fertility. The acid rain has a corroding effect on buildings and metallic structures.

(v) The oxides of nitrogen can cause fading of dyes used in colouring textiles.

#### Sinks of Oxides of Nitrogen

The oxides of nitrogen are not very stable. The average life of NO is 4 days and that of  $NO_2$  is 3 days. During this period, either the oxides are decomposed into  $N_2$  and  $O_2$  or converted into nitric acid through the following reactions:

$$2NO + O_2 \longrightarrow 2NO_2$$

$$3NO_2 + H_2O \longrightarrow 2HNO_3 + NO$$

$$4NO_2 + 2H_2O + O_2 \longrightarrow 4HNO_3$$

Nitric acid comes down from the atmosphere to the surface of the earth in the form of acid rain. The acid reacts with bases to form nitrates.

Some natural processes and photochemical reactions also remove oxides of nitrogen in the atmosphere and serve as sinks.

#### Control of NO<sub>X</sub> Pollution

(i) The flue gases coming out from power plants or industrial units can be made from oxides of nitrogen and SO<sub>2</sub> by

scrubbing them with alkaline solutions of Ca(OH)<sub>2</sub> and Mg(OH)<sub>2</sub> or with sulphuric acid. The following reactions occur when H<sub>2</sub>SO<sub>4</sub> is used for scrubbing.

$$NO_2 + SO_2 + H_2O \longrightarrow H_2SO_4 + NO$$
  
 $NO + NO_2 \longrightarrow N_2O_3$   
 $N_2O_3 + 2H_2SO_4 \longrightarrow 2NOHSO_4 + H_2O$ 

The flue gases thus freed from  $NO_2$  and  $SO_2$  are released into atmosphere.

(ii) Catalytic converters are used in automobiles which convert the vehicular exhausts into free nitrogen and traces of ammonia.

#### 4. Hydrocarbons ( $C_XH_Y$ )

These are the chemical compounds of carbon and hydrogen only. These can be saturated or unsaturated, branched or straight chain or can have a ring structure. The most important hydrocarbons involved in air pollution are those which are volatile or in gaseous state under ordinary atmospheric conditions. The hydrocarbons in air by themselves alone cause no harmful effects. They are of concern because hydrocarbons undergo chemical reactions in the presence of sunlight and nitrogen oxides forming photochemical oxidants of which the predominant one is ozone. Methane is the main hydrocarbon present in atmosphere. The other hydrocarbons present are ethane, ethylene, acetylene, propane, n-butane, isopentane, toluene, n-pentane, m-xylene, isobutane, etc.

#### **Sources**

- (a) Natural sources: (i) Methane is emitted in large quantities during anaerobic decomposition of organic matter in soil, water and sediments.
- (ii) Forest fires and trees emit large amounts of hydrocarbons into atmosphere.
- **(b) Man-made sources:** (i) Incomplete combustion of fossil fuels in industry and thermal power plants and the exhaust of automobiles are releasing unburnt hydrocarbons into the atmosphere. This source contributes about 15% hydrocarbons.
- (ii) Solvents used in many industrial operations escape into air due to evaporation. This contributes about 10% to the total hydrocarbon pollution.

**Harmful effects:** (i) Hydrocarbons, particularly aromatic cause irritation in eyes, nose, lungs, etc. Hydrocarbons are carcinogenic, *i.e.*, they cause cancer.

- (ii) Hydrocarbons harm plants by causing ageing, breakdown of tissues and shedding of leaves, flowers and twigs.
- (iii) Methane is an important greenhouse gas which can trap 20 times more heat as compared to carbon dioxide.
- (iv) Hydrocarbons undergo chemical reactions in the presence of sunlight and oxides of nitrogen forming photochemical oxidants and photochemical smog which have highly harmful effects on human being as well as plants.

#### 5. Particulates or Suspended Particles

In general the term **particulate** refers to all atmospheric substances that are not gases, *i.e.*, they are minute solid particles or liquid droplets or mixtures of the two in air. Particulates can be composed of inert or extremely reactive materials of varying size. Particulate matter may be viable or non-viable. The viable particulates are the minute living organisms that are dispersed in the atmosphere. It includes bacteria, fungi, moulds, etc. The non-viable particulates are the different chemical substances which enter the atmosphere from various sources.

The size of the particulates ranges from a diameter of  $0.0002~\mu$  (about the size of a small molecule) to a diameter of about 500  $\mu$  (1  $\mu$  =  $10^{-6}$  m). The life-time of the particulates also ranges between a few seconds and several months. This life-time depends upon the settling rate which in turn is dependent on the size and density of the particles and the turbulence of the air. Particulates have the ability to act as sites for sorption. This property depends on the surface area which is large for most of the particulates. The process of sorption occurs when an individual molecule impacts on the surface of a particulate and does not rebound but sticks or sorbs.

**Sources of particulates:** There are four main types of non-viable particulate matter in the atmosphere. These are mists, smoke, fumes and dusts.

- (a) Mists: These are those particles that are produced by spray liquids and formed by the condensation of vapours in air. Examples, of this type can be portions of insecticides and herbicides that miss their targets and travel through the air.
- (b) Smoke: It contains very small soot particles which can be liquid or solid. These are produced by burning and combustion of organic matter. Oil smoke, tobacco smoke and carbon smoke are typical examples of this type.
- (c) Fumes: These are condensed vapours. Fumes of metals are the well known particulates of this type. These are normally released from chemical or metallurgical processes.
- (d) Dust: These are the fine particles formed by natural disintegration of rocks and soil or by mechanical processes of grinding, crushing, etc. Particles from soils and minerals contain calcium, aluminium and silicon compounds. Very small solid particles are carbon black, silver iodide combustion nuclei and sea salt nuclei. Larger particles are cement dust, soil dust, foundary dust, and pulverised coal. Liquid particulate matter generally categorised as "mist" includes rain drops, fog and sulphuric acid mist.

Thus both the natural and man-made sources contribute the airborne matter. The important natural sources are: (i) volcanic eruptions (ii) blowing of dust and soil by wind (iii) sea salt sprays (iv) forest fires (v) vegetation. The man-made sources are: (i) vehicular exhaust (ii) combustion processes (iii) metallurgical operations (iv) mining operations, etc. The given points are the **primary particulates.** 

Particulates produced in the atmosphere as a result of chemical reactions are called **secondary particulates.** These are formed either in gas phase reactions or by heterogeneous reactions between gases and already existing primary particulates. The majority of secondary particulates possess a diameter less than 1µ. The reaction leading to the formation of secondary particulates are largely catalysed by sunlight. The chief chemical reactants are sulphur oxides, nitrogen oxides, ammonia, water vapour and hydrocarbons.

#### **Some Common Particulates**

- (i) Soot: It is produced by incomplete combustion of carbonaceous fossil fuels such as coal, wood, natural gas, gasoline, etc., in low supply of oxygen.
- (ii) Fly ash: It comes from the combustion of high ash fossil fuels used in thermal power plants and smelters.
- (iii) Metal particles: These are released by various metal finishing operations. Micro particles of toxic metals are highly harmful.
- (iv) Metal oxides: These are produced by combustion of fuels with metallic compounds. For example, Fe<sub>3</sub>O<sub>4</sub> is produced by the combustion of coal containing iron pyrites.

$$3\text{FeS}_2 + 8\text{O}_2 \longrightarrow \text{Fe}_3\text{O}_4 + 6\text{SO}_2$$

(v) Lead salts: These come into atmosphere through exhaust gases from automobiles when lead tetraethyl  $[Pb(C_2H_5)_4]$  is used as antiknocking agent along with  $C_2H_4Cl_2$  and  $C_2H_4Br_2$  in gasoline.

$$\begin{aligned} \text{2Pb}(\text{C}_2\text{H}_5)_4 + \text{C}_2\text{H}_4\text{Cl}_2 + \text{C}_2\text{H}_4\text{Br}_2 + 32\text{O}_2 &\longrightarrow \text{PbCl}_2 \\ &+ \text{PbBr}_2 + 20\text{CO}_2 + 24\text{H}_2\text{O} \end{aligned}$$

- (vi) Asbestos dust: Asbestos dust is introduced in atmosphere by industries manufacturing asbestos sheets, ropes, etc.
- (vii) Acid mist: Sulphuric acid and nitric acid mists are produced when oxides of sulphur and nitrogen dioxide come in contact with moisture.

$$2SO_2 + O_2 + 2H_2O \longrightarrow 2H_2SO_4$$
  
 $4NO_2 + 2H_2O + O_2 \longrightarrow 4HNO_3$ 

(viii) Organic particulates: Paraffins, olefins and aromatic compounds particularly polycyclic aromatic hydrocarbons are emitted from petroleum refineries and automobiles. The polycyclic hydrocarbons are easily adsorbed on the soot particles and become serious health hazards.

#### Harmful Effects of Particulate Pollutants

(i) Effect on human beings: Small sized particulates which can pass through the nose and enter into lungs easily are highly dangerous. These particulates in lungs act as excellent sites for adsorption of carcinogenic compounds such as

polynuclear hydrocarbons and asbestos, etc., and bring lung diseases such as lung cancer, bronchital asthma and chronic bronchitis. The lung diseases are common in industrial workers.

Different types of particulates cause different types of lung diseases. For example,

- (a) Asbestos causes asbestosis.
- (b) Coal miners suffer from black lung disease.
- (c) Textile workers suffer from white lung disease.
- (d) Dust having free silica causes silicosis.
- (e) Beryllium compounds cause beryllosis.

Many biological particulates in the air, e.g., bacteria, fungal spores, pollen grains quite often cause allergy and bronchitis in man.

The following non-viable particulates exert adverse effects on human health.

- (a) Cadmium oxide Prostrate cancer, high blood pressure

  (b) Benzene Blood cancer (Leukemia)

  (c) Vinyl chloride Sarcoma of liver

  (d) Arsenic Lung, skin and liver cancer

  (e) Benzidine Bladder cancer

  (f) Lead particles Nervous diseases
- (ii) Effect on plants: Particulates deposit on the leaves of the plants. The common damage occurs in leaf structure such as *necrosis*, *chlorosis* and *epinasty*. They destroy chlorophyll and disrupt photosynthesis. Particulates block the stomata and retard the transpiration of minerals from the soil.
- (iii) Effect on materials: Large number of materials are damaged by particulates. Soot, dust, fumes, mists, etc., badly affect paints, clothes, buildings, sculptures, monuments, etc., corrosion of metals is accelerated in humid atmosphere. Particulates also damage electronic equipment.
- (iv) Effect on visibility: Particulates display optical properties which exert an important effect on air quality. They cause scattering and absorption of sunlight and reduce the visibility. They also produce blurring effect on vision.

#### Control of Particulate Pollution

The methods of control of particulates are based on settling or washing.

- (a) Gravity settling chamber: Effluent gases are allowed to enter a horizontal large rectangular chamber. The velocities of the gases decrease and the larger particles settle down under the influence of gravity.
- **(b) Wet scrubbers:** In this method, the effluent gases are allowed to enter a spray tower or chamber. A suitable liquid (generally water) is introduced in the form of a fine spray which washes away the particulates.
- **(c) Electrostatic precipitator:** It is the most effective and efficient method. The particulates are removed by installation of an electrostatic precipitator in the chimney. When a high potential is applied across the chimney, the carbon particles are

attracted by the charged electrodes. This results in the formation of soot which gets deposited in the chimney which is cleaned from time to time. Similarly, the particulates coming in the exhaust of automobiles are removed by catalytic converter.

In some of the industries, the filters are used to remove particulates. These filters work like the filters are used in air conditioners or vacuum cleaners. The exhaust gases are passed through them, leaving particulates and aerosols behind the filter.

#### Some other Air Pollutants

(a) Carbon dioxide ( $CO_2$ ): Carbon dioxide is a natural constituent of atmosphere and is vital for all forms of plant life. Normally, it forms about 0.03% by volume of atmosphere.

It is a colourless, odourless gas and is about 1.5 times heavier than air. Though it is non-poisonous, it does not support life as animals and human beings die in its atmosphere due to lack of oxygen. Carbon dioxide present in normal concentration is not an air pollutant. However, when CO<sub>2</sub> level increases in atmosphere, it results in global warming (called greenhouse effect-discussed later). Hence, it is considered to be pollutant in large amounts.

#### Major sources of CO<sub>2</sub> in atmosphere

- (i) Burning of fossil fuels like coal, natural gas and petroleum, etc.
- (ii) Industrial processes such as manufacture of lime, alcohol and other fermentation units.
- (iii) Biological decay of plants.
- (iv) In the process of respiration by animals, human beings and plants.

#### Sinks (Major consumers) of CO<sub>2</sub>

- (i) Green plants use CO<sub>2</sub> in presence of sunlight and chlorophyll to produce carbohydrates—photosynthesis.
- (ii) Oceans dissolve CO<sub>2</sub> to form carbonates, bicarbonates and organic compounds.

A balance of  $CO_2$  in the atmosphere is to be maintained. However, human activities have disturbed this balance and  $CO_2$  level in atmosphere is in increasing order. The increasing concentration of  $CO_2$  has changed global climatic conditions especially raising the global temperature.

- (b) Hydrogen sulphide (H<sub>2</sub>S): It is a colourless gas having smell of rotten eggs. It is extremely toxic and harmful even at low concentrations. The sources which release hydrogen sulphide into the atmosphere are:
  - (i) Natural decay of animals and vegetable matter
  - (ii) Volcanic eruptions
  - (iii) Industrial process like paper mills, oil refineries, chemicals manufacturing plants using sulphur.

#### **Sinks**

H<sub>2</sub>S is readily oxidised to SO<sub>2</sub> in the atmosphere.

$$H_2S \xrightarrow{O_2} SO_2 + H_2O$$

$$H_2S \xrightarrow{O_3} SO_2 + H_2O$$

It may combine with various metal compounds to form insoluble sulphides.

Mild exposure to  $H_2S$  can cause giddiness. In higher concentrations, it can be fatal. It is harmful to plants also as it affects leaves and reduces their growth.

(c) Chlorine (Cl<sub>2</sub>): Chlorine is a greenish-yellow coloured gas having disagreeable suffocating, poisonous and toxic gas. It does not occur as an air pollutant on a large scale. However, it can be highly dangerous on a local scale.

It is mostly released in the atmosphere by industrial processes from plastic industries, water treatment units and plants engaged in the manufacture of caustic soda.

In the atmosphere, chlorine dissolves in moisture to form hydrochloric acid and hypochlorous acid. These acids come down to the earth in the form of acid rain.

$$H_2O + Cl_2 \longrightarrow HCl + HClO$$

Chlorine causes irritation in mucus membrane. Exposure to chlorine for longer time may cause death.

- (d) Aldehydes: Out of the numerous aldehydes that may find their way into the atmosphere, only acrolein and formaldehyde have been detected in some areas with concentrations that may be toxic. Aldehydes are formed due to incomplete combustion of fossil fuels. These are also formed in the atmosphere by the interaction of hydrocarbons and oxides of nitrogen in presence of sunlight. The aliphatic and aromatic aldehydes are important precursors of the notorious peroxy-acyl nitrates (PAN) and peroxy-benzoyl nitrates (PBN) which act as photochemical oxidants.
- (e) Fluorides: Fluorides are present in the air of both rural and urban areas. The sources may be natural or industrial byproducts. Industrial processes of phosphate fertilizers, ceramics, aluminium, fluorinated hydrocarbons (freons-refrigerants aerosols, propellants, etc.), fluorinated plastics, etc., are the main sources of fluorides in atmosphere. These act as pollutants either in gaseous or particulate state. Freons when reach to upper atmosphere disturb the ozone layer.

#### **EFFECTS OF AIR POLLUTION**

### 19.7 ACID RAIN

The term 'acid rain' is used to describe all precipitations-rain, snow, fog, dew—which are more acidic than normal. The normal rain is slightly acidic having a pH of about 5.6 as carbon dioxide gas reacts with it to form a weak carbonic acid.

$$CO_2 + H_2O \longrightarrow H_2CO_3$$
 (Carbonic acid-weak acid)

As carbon dioxide is present in unpolluted air in traces the acidity is extremely mild and may be regarded as neutral. Acid rain, thus, refers to any precipitation which has pH less than 5.6. The pH of the acid rain can range between 5.6 and 3.5 and in some cases even lower upto 2.

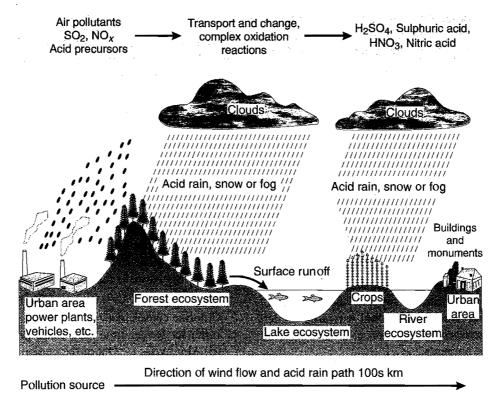

Fig. 19.2 Acid rain

Chemistry of acid rain: Acid rain results from the presence of two strong acids in polluted air: H<sub>2</sub>SO<sub>4</sub>, and to a lesser extent, HNO<sub>3</sub>.

Nitric acid comes largely from a three-step process. The first step involves the formation of NO from the elements by high temperature combustion, as in automobile engines or lightning in the atmosphere during the rainy season. This is then oxidised to NO<sub>2</sub> at normal atmospheric conditions. NO<sub>2</sub> combines with water to form a mixture of nitrous and nitric acids.

$$\begin{array}{c} N_2 + O_2 \xrightarrow{\mbox{High temp.}} 2NO \\ 2NO + O_2 \xrightarrow{\mbox{}} 2NO_2 \\ 2NO_2 + H_2O \xrightarrow{\mbox{}} HNO_3 + HNO_2 \end{array}$$

Coal, used in power plants, contains upto 4% sulphur, mostly in the form of minerals such as pyrite, FeS<sub>2</sub>. The combustion of coal forms sulphur dioxide. Petroleum products also on combustion release sulphur dioxide.

$$4FeS_2 + 11O_2 \longrightarrow 2Fe_2O_3 + 8SO_2$$
$$S + O_2 \longrightarrow SO_2$$

Large quantities of SO<sub>2</sub> are also produced in the metallurgical processes used to treat sulphide ores.

$$2NiS + 3O_2 \longrightarrow 2NiO + 2SO_2$$

Natural processes such as volcanic eruptions, forest fires and bacterial decomposition of organic matter can produce the oxides of sulphur and nitrogen.  $SO_2$ , when it comes in contact with water, forms sulphurous acid ( $H_2SO_3$ ).

$$SO_2 + H_2O \longrightarrow H_2SO_3$$
 (Sulphurous acid)

SO<sub>2</sub> is partly and slowly converted into sulphur trioxide by molecular oxygen in presence of dust particles

$$2SO_2 + O_2 \xrightarrow{Dust particles} 2SO_3$$
  
 $SO_2$  is also oxidised to  $SO_3$  by ozone  
 $SO_2 + O_3 \xrightarrow{} SO_3 + O_2$ 

SO<sub>3</sub> thus formed readily combines with water and produces sulphuric acid as tiny droplets high in the atmosphere. These may be carried by the prevailing winds as far as 1500 km.

$$SO_3 + H_2O \longrightarrow H_2SO_4$$
 (Sulphuric acid)

The sulphuric acid and nitric acid, thus formed remain as vapour under high temperature and begin to condense slowly as the temperature falls. These acids mix with rain or snow, *i.e.*, rain water gets acidified on its way down to the earth. The acidified rain water eventually mixes with the already existing water on the earth. The resulting pH determines the pH of the aquatic environment.

The presence of hydrogen sulphide and chlorine in the atmosphere also contributes to the formation of acid rain.

The acid rain is not confined to the regions where the harmful pollutants are emitted. Since winds carry atmospheric pollutants across national borders, the acid rain may fall hundred of miles away from the pollution sources.

#### Consequences of Acid Rain

- (i) Damage to animals: Acid rain causes lakes and rivers to become acidic and drop in pH can destroy the ecological balance. Most aquatic animals cannot survive when the pH is less than 4. Some species of fish such as salmon die even when the pH is less than 5.5. Certain species of algae and zooplankton are eliminated at pH less than 6. A reduction in the zooplankton and bottom fauna will affect the food availability for the fish population.
- (ii) Damage to plants: Acidic water is dangerous for plants. Leaf pigments are decolourised, *i.e.*, chlorophyll is affected and agricultural productivity is decreased. Several non-woody plants (such as barley, cotton) and fruit trees (such as apple, pear) are among the most susceptible to acid rain.

Many soils contain limestone and have natural buffering properties, but without this the acidified soil means plant nutrients are leached from the soil. Aluminium is released damaging root systems, seeds stop germinating, helpful soil organisms are killed.

$$\begin{array}{c} Al(OH)_3 + 3H^+ \longrightarrow & Al^{3+} + 3H_2O \\ \hline & Soluble \\ & (Toxic in nature) \end{array}$$

(iii) Material damage: Metallic surfaces exposed to acid rain are readily corroded. Textile fabrics, paper and leather products lose their material strength or disintegrate by the acid rain.

Building materials (limestone, marble, dolomite, mortar and slate especially) are weakened on reaction with acid rain as water-soluble compounds are formed. Thus, acid, rain is dangerous for historical monuments.

$$CaCO_3 + H_2SO_4 \longrightarrow CaSO_4 + H_2O + CO_2$$

The big industries emitting sulphur dioxide should not be established in urban areas and near the historical monuments.

(iv) Effect on human beings: Acid rain also affects human beings directly. The release of toxic metals held in rocks, especially aluminium, mercury and cadmium into water sources by acid rain can cause poisonous levels of metals to build in the fish which we eat. Acidic drinking water reacts with our water ducts and metal concentrations can cause damage to the kidneys and liver and diarrhoea in young children.

#### Ways to Minimise the Formation of Acid Rain

To reduce acid rain, sulphur dioxide emissions from power plants and smelters must be brought under control. The most direct approach is to remove sulphur from fossil fuels before combustion, but this is technically difficult to accomplish. A cheaper method is to remove SO<sub>2</sub> as it is formed. For example, in one process, powdered limestone is injected into the power plant furnace along with coal (Fig. 19.3). At high temperature, the following decomposition occurs:

$$\begin{array}{ccc} CaCO_3 & \longrightarrow & CaO + CO_2 \\ \text{Limestone} & & \text{Quick lime} \end{array}$$

The quick lime reacts with SO<sub>2</sub> to form calcium sulphite and some calcium sulphate.

$$\begin{array}{c} \text{CaO} + \text{SO}_2 \longrightarrow \text{CaSO}_3 \\ \text{2CaO} + 2\text{SO}_2 + \text{O}_2 \longrightarrow \text{2CaSO}_4 \end{array}$$

To remove the remaining SO<sub>2</sub>, an aqueous suspension of quick lime is injected into a purification chamber prior to the escape of gases through the smokestack.

$$Ca(OH)_2 + SO_2 + (\frac{1}{2}) O_2 \longrightarrow CaSO_4 + H_2O$$

One problem with this approach is that it produces large quantities of solid calcium sulphate as a waste product.

Quick lime is also added to lakes and soils affected by acid rain. This process is called **liming.** 

. Installing of a sulphuric acid plant near a metal ore smelting site is also an effective way to cut sulphur dioxide emission.

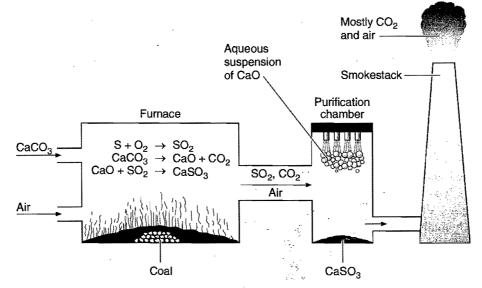

Fig. 19.3 Common procedure for removing  $SO_2$  from burning fossil fuel. Powdered limestone decomposes into CaO, which reacts with  $SO_2$  to form  $CaSO_3$ . The remaining  $SO_2$  then enters a chamber where it reacts with an aqueous suspension of CaO to form  $CaSO_3$ .

To do away with acid rain, an international programme, involving all the countries in order to take concrete measures to minimise sulphur dioxide pollution which travels very fast in atmosphere, is the need of the hour.

#### The Taj Mahal Protection from Air Pollution

Taj Mahal, one of the seven wonders of the world, situated at Agra, is losing its lustre day by day due to ill effects of air pollution mainly of acid rain. Agra and its adjoining areas such as Firozabad, Mathura, Bharatpur, etc., are having 2000 polluting industries. These include cast iron foundries, rubber manufacturing units, brick kilns, glass works and government owned petroleum refinery at Mathura. Due to rapid industrialization and increased growth of vehicular traffic, Agra city has abundance of oxides of sulphur and nitrogen in its atmosphere. These react with water vapour to form various acids which act on Taj's marble. As a result, there is continuous deterioration of this classical building which is the country's best loved landmark.

The government of India announced an action plan in 1995 to clean up the atmosphere which is affecting Taj Mahal. Marble of Taj Mahal must be guarded with protective coating which could resist the action of air pollutants. The industries located in nearby areas have been asked either to shift to other areas or to start using natural gas or liquefied petroleum gas for heating purpose. People living in the city have been advised to use LPG in place of coal, kerosene or firewood. If due protection of Taj is not provided then rapid weathering of its stone structure would occur.

### 19.8 SMOG

The word **smog** was coined to describe the combination of smoke and fog.

The name was proposed to describe the phenomenon which occured due to condensation of some kind of fog on the carbon particles present in the smoke produced due to combustion of fuels like coal and petroleum.

Smog is of two types:

- (i) Classical smog
- (ii) Photochemical smog
- (i) Classical smog: It is also called London smog or sulphurous acid smog. This was observed in London in 1952 and killed about 4000 to 5000 people. This type of smog is produced from gases like SO<sub>2</sub>, particulates and high humidity in the atmosphere. The particulates catalyse the oxidation of SO<sub>2</sub> to SO<sub>3</sub> which gets mixed with moisture in the tiny droplets of fog producing sulphuric acid drops which

condense on particulates of smoke or dust to give colloidal dispersion called smog.

$$2SO_2 + O_2 \longrightarrow 2SO_3$$
  
 $SO_3 + H_2O \longrightarrow H_2SO_4$ 

This type of smog is usually formed during winter season in the early morning hours. However, after sunrise, its intensity increases due to photochemical oxidation of  $SO_2$  to  $SO_3$ . It occurs in the lower part of the atmosphere. It decreases visibility and is responsible for breathing troubles like bronchitis and asthma. It produces irritation to eyes, nose and throat. The London smog is also called **reducing smog** as it contains  $SO_2$  and carbon.

(ii) Photochemical smog: It is also called Los Angeles smog as it was observed for the first time in Los Angeles in 1950. This type of smog is formed by combination of particulates (smoke, dust, fog) with oxides of nitrogen and hydrocarbons in presence of sunlight. As photochemical reactions are involved in the formation of smog, it is called photochemical smog. It occurs in those areas which have warm, sunny and dry climate along with the atmosphere has large concentration of automobile exhausts. It usually occurs in the months of summer during the day time. Photochemical smog is characterized by brown haze of irritating nature. It is oxidising in character as it has high concentration of oxidants.

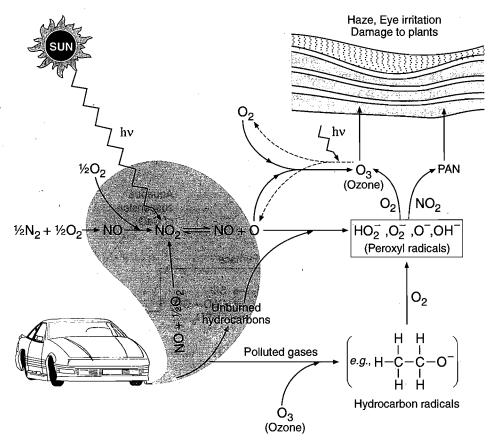

Fig. 19.4 Some main chemical reaction taking place in photochemical smog

Formation of photochemical smog: Smog begins with primary pollutants, substances that may be harmless and unreactive by themselves. Secondary pollutants, formed photochemically from the primary pollutants, are responsible for the buildup of smog. Primary pollutants consist mainly of nitric oxide, carbon monoxide and various unburned hydrocarbons.

Nitric oxide released into the atmosphere is quickly oxidised to nitrogen dioxide.

$$2NO + O_2 \longrightarrow 2NO_2$$

Sunlight causes photochemical decomposition of NO<sub>2</sub> (wavelength shorter than 400 nm) into NO and O.

$$NO_2 + hv \longrightarrow NO + O$$

Atomic oxygen is a highly reactive species that can initiate a number of important reactions, one of which is the formation of ozone.

$$O_2 + O + M \longrightarrow O_3 + M$$

where M is an inert gas such as nitrogen. It takes up the excess energy. Ozone attacks the C = C linkage in rubber.

where R represents groups of C and H atoms. In 'smoggy' areas, this reaction can cause automobile tyres to crack. Similar reactions are also damaging lung tissues and other biological substances.

A second process involving the participation of unburned hydrocarbons may be depicted as:

$$O + RH \longrightarrow R^{\bullet} + RCO^{\bullet}$$

$$RCO^{\bullet} + O_{2} \longrightarrow RCO_{3}^{\bullet}$$

$$RCO_{3}^{\bullet} + NO_{2} \longrightarrow RCO_{3}NO_{2}$$

$$(Peroxyacyl nitrate, PAN)$$

$$O \longrightarrow CH_{3}$$

PAN is a powerful lachrymator or tear producer and causes breathing troubles.

Extensive research has shown that carbon monoxide plays a very important role in the production of smog and the process is a dynamic one. When aldehydes are attacked by atomic oxygen, hydroxyl radicals are formed which lead to a series of reactions.

$$RCHO + O \longrightarrow RCO + OH$$
  
 $OH + CO \longrightarrow CO_2 + H$   
 $H + O_2 + M \longrightarrow HO_2 + M$   
 $HO_2 + NO \longrightarrow OH + NO_2$ 

The overall reaction is:

$$CO + O_2 + NO \longrightarrow CO_2 + NO_2$$

Fig. 19.5 shows a typical variation with time of primary and secondary pollutants. Initially, the concentration of NO<sub>2</sub> is quite low. As soon as solar radiation penetrates the atmosphere, the concentration of NO2 increase. The concentration of O3 remains fairly constant at a low level in the early morning hours. As the concentration of unburned hydrocarbons and aldehydes increases in the air, the concentrations of NO2 and O<sub>3</sub> also rise rapidly. The actual amounts, of course, depend on the location, traffic and weather conditions, but their presence is always accompanied by haze. The oxidation of hydrocarbons produces various organic intermediates, such as alcohols and carboxylic acids which are all less volatile than hydrocarbons. These substances eventually condense into small droplets of liquid. The dispersion of these droplets in air, called aerosols, scatters sunlight and reduces visibility. This interaction makes the air look hazy.

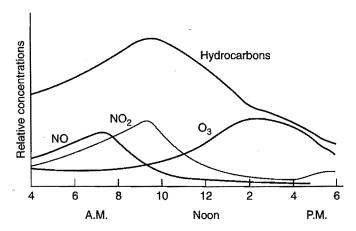

Fig. 19.5 Typical variation with time in concentration of air pollutants on a smoggy day

Effects of photochemical smog: The adverse effects of photochemical smog pose a potential threat not only to the local environment but to the far away places as well. Although photo-oxidants are formed mainly in highly industrialised and urban areas, the effect of smog can be observed even at a distance of 1000 km from the source region.

Smog is known to cause eye irritation, cough, chest discomfort and fatigue in humans. Peroxyacetyl nitrate is an etiological agent in the growing incidence of skin cancer. Ozone damages the membranes surrounding pulmonary capillaries.

Compared to human beings, vegetation is more prone to the harmful effects of oxidants. Ozone cause a reduction in plant growth. High concentrations of ozone damage forests. Organic oxidants act as poisons to plants.

Ozone may cause harm to fibres, dyes, paints and polymers. Natural rubber and synthetic polymers become brittle and crack.

Control of photochemical smog: Photochemical smog can be suppressed by the following technologies:

(i) Catalytic converters: The most straight forward way of reducing smog formation is to minimise the release of

oxides of nitrogen and hydrocarbons to the atmosphere. This involves installation of efficient catalytic converters in the automobiles. The harmful gases are converted catalytically into harmless gases. The limitation, however, is that catalytic converters work with unleaded petrol since lead poisons the catalysts.

A two way catalytic converter removes hydrocarbons and carbon monoxide from the exhaust. It consists of a mixture of platinum and palladium supported on ceramic or metal honey comb bed. It operates at an exhaust temperature of about 450°C and removes about 50% of the pollutants. Carbon monoxide is oxidised to carbon dioxide and hydrocarbons to carbon dioxide and water.

$$\begin{array}{ccc}
2\text{CO} + \text{O}_2 & \xrightarrow{\text{Catalyst}} & 2\text{CO}_2 \\
\text{HC} + \text{O}_2 & \xrightarrow{\text{Catalyst}} & \text{CO}_2 + \text{H}_2\text{O}
\end{array}$$

A three way catalyst removes hydrocarbons, carbon monoxide and nitrogen oxides from the auto exhaust. It is an example of oxidation-reduction catalysis.

$$2NO + 2CO \xrightarrow{\text{Catalyst}} N_2 + 2CO_2$$

$$2NO + CO \xrightarrow{\text{Catalyst}} N_2O + CO_2$$

$$2N_2O \xrightarrow{\text{Catalyst}} 2N_2 + O_2$$

$$NO_2 + HC^* \xrightarrow{\text{Catalyst}} N_2 + CO_2 + H_2O$$

$$NO + HC^* \xrightarrow{\text{Catalyst}} N_2 + CO_2 + H_2O$$

The three way catalyst consists of a mixture of platinum, palladium and rhodium deposited on a high surface area ceramic and metal honeycomb.

(ii) Chemical method: Photochemical smog can be suppressed by certain compounds which act as free radical traps. When these compounds are sprayed to the atmosphere, they generate free radicals which readily combine with free radical precursors of photochemical smog (such as  $O^{\bullet}$ ,  $R^{\bullet}$ ,  $RO^{\bullet}$ ,  $H^{\bullet}$  etc.). The compound diethylhydroxylamine, has been found to possess smog inhibiting characteristics. However, it produces an unpleasant odour.

### 19.9

# GREENHOUSE EFFECT AND GLOBAL WARMING

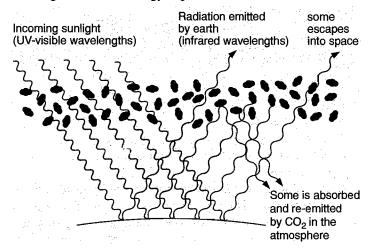

The greenhouse effect received its name because the earth's atmosphere acts much like the glass or plastic roof and walls of a greenhouse. Sunlight enters a greenhouse through the transparent glass or plastic and heat the plants but the heat emitted by the plants in the form of infrared radiation cannot pass through the glass or plastic roof and walls. As a result, the temperature inside the house increases. An effect similar to greenhouse is responsible for keeping the earth's surface warmer than it would otherwise be. Atmosphere around the earth acts like a glass of the greenhouse chamber. The gases present in atmosphere which are responsible for greenhouse effect are called greenhouse gases. The various gases which bring greenhouse effect are:

\*HC = Hydrocarbon

Carbon dioxide, water vapours, oxides of nitrogen, methane, ozone, chlorofluorocarbons, etc.

Although carbon dioxide is only a trace gas in earth's atmosphere with a concentration of 0.33 per cent by volume, it plays a critical role in controlling the climate of the earth. Without greenhouse effect, the average surface temperature of the earth would be about 35°C lower than it is today.

The major source of the earth's energy is the sun. About half of the radiant energy that strikes our atmosphere is either reflected or absorbed by the molecules that make up this envelope of the air. The sunlight that reaches the earth's atmosphere is ultraviolet, visible and infrared ranges between 100 and 5000 nm. However, UV radiations of shorter wavelengths are prevented from entering the troposphere by the presence of oxygen and ozone layer in the stratosphere. The rays that do reach the surface of the earth are largely in the visible and infrared (heat) regions. These radiations are absorbed by the earth and as a result, the continents and oceans are warmed. Warm bodies emit radiation and earth is no exception. Most of the radiation emitted by earth lies in the infrared region (wavelengths longer than 4000 nm). The rate at which energy escapes the surface of the earth is over twice the rate at which the planet directly absorbs energy from the sun. This means that the earth acts a little like an extravagant person. If this process were the only one to be occurring, the earth would be a very cold place. Fortunately, the planet does something extra to maintain the heat balance. Almost 84% of the heat radiated by the earth is absorbed by gases in the atmosphere and reradiated back to the earth's surface. As a result of this exchange, the total energy input from the sun balances the

**Fig. 19.6** The role of atmospheric CO<sub>2</sub> in the greenhouse effect. Carbon dioxide is transparent to incoming sunlight, but it absorbs and re-emits a significant amount of the infrared radiation emitted by the earth. This alters earth's energy balance, raising its average temperature

Environmental Chemistry 947

energy output from the earth. A steady state is established, with more or less constant average terrestrial temperatures. It is the return of 84% of the energy radiated from the surface of the earth that has been termed the global greenhouse effect. (Fig. 19.6)

The constituents of the atmospheric greenhouse are made of molecules that are transparent to visible light, but absorb in the infrared region. Nitrogen and oxygen, the major components of the atmosphere are transparent to IR-radiations. However, some tracer gases in the troposphere are strong IR-radiation absorbers. These gases are carbon dioxide, water vapours, methane, ozone, chlorofluorocarbons, etc. These gases are transparent to sunlight, absorb IR-radiations emitted by earth and re-emit still longer wavelength IR-radiation, most of which return to the earth's surface where they are reabsorbed. This process keeps the temperature from falling dramatically at night when the ground is no longer absorbing energy from the sun.

The gases which are transparent to sunlight and are capable of absorbing IR-radiations and then re-emitting IR-radiations of longer wavelengths are termed greenhouse gases.

Upon receiving a photon in the IR region, a CO<sub>2</sub> or a H<sub>2</sub>O molecule is promoted to a higher vibrational energy level.

$$CO_2 + hv \longrightarrow CO_2^*$$
  
 $H_2O + hv \longrightarrow H_2O^*$ 

The energetically excited molecules soon lose their excess energy either by collision with other molecules or by spontaneous emission of radiation. Part of this radiation is emitted to outer space and the rest returns to the earth's surface keeping it comparatively warmer. The degree of temperature control depends on the amount of carbon dioxide and water vapour in the atmosphere. In desert regions, where the amount of water is very low and at high altitudes where the atmosphere is less dense, day and night temperature variations are much more severe than at lower altitudes having humidity. If it were not for the presence of these two relatively minor components of the atmosphere (CO<sub>2</sub> and H<sub>2</sub>O), the earth would be essentially barren of life. Its mean temperature would have been about -15°C, roughly 35°C lower than what it is today. In this way it can be said that CO<sub>2</sub> and H<sub>2</sub>O vapour act as an insulating blanket to prevent heat from escaping to outer space.

#### **Global Warming**

Whereas the total amount of water vapour in our atmosphere has not altered noticeably over the years, the carbon dioxide concentrations have risen by about 25% in the past century. This increase is as a result of extra burning of fossil fuels (petroleum, natural gas and coal) in order to meet the energy needs. Fig. 19.7 shows the increase in CO<sub>2</sub> concentration from the year 1958 to year 1992 (from 310 ppm to 360 ppm). The zig-zag line is a consequence of seasonal variation.

Other measurements indicate that during the past nearly 120 years, the average temperature of the planet has increased by somewhere between 0.4 and 0.8°C. Current estimates are that doubling the CO<sub>2</sub> concentration will result in a temperature increase of between 1.0 to 3.5°C. Recent estimates suggest that about half of the global warming may be attributable to

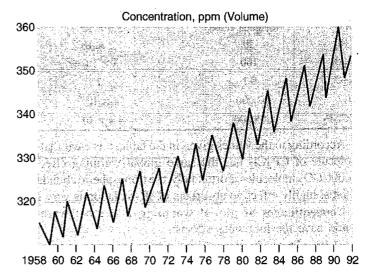

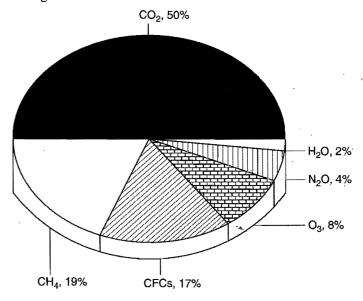

Fig. 19.7 Carbon dioxide levels (1958–1992) in the atmosphere are increasing exponentially

compounds other than carbon dioxide. Fig. 19.8 shows the relative contribution of various gases to greenhouse effect. The contribution of CO<sub>2</sub> is 50% while the contribution of other trace gases is also about 50%.

**Fig. 19.8** Relative contribution of radiatively active gases to greenhouse effect

The amount of warming which a greenhouse gas imparts to a square metre of the earth is called **radiative forcing**. The radiative forcing exerted by each greenhouse gas depends on its concentration and its ability to absorb long wavelength IR-radiation. The effectiveness is quantified by the greenhouse factor, a number that represents the relative contribution of a molecule of the gas to global warming. Values of the greenhouse factor for six common trace gases and their average concentrations in the troposphere are given in the following table.

Gas	Greenhouse factor	Tropospheric abundance (%)
CO <sub>2</sub>	1 (assigned value)	$3.6 \times 10^{-2}$
$CH_4$	' 30	$1.7 \times 10^{-3}$
N <sub>2</sub> O	160	$3 \times 10^{-4}$
$H_2O$	0.1	1
$O_3$	2,000	$4 \times 10^{-6}$
CCl <sub>2</sub> F <sub>2</sub>	25,000	$4.8 \times 10^{-8}$

According to the values given in the table, it is clear that one molecule of CF<sub>2</sub>Cl<sub>2</sub> has the same global warming effect as 25,000 CO<sub>2</sub> molecules. Fortunately, the tropospheric abundance of most highly effective absorbers of IR-radiation is very low.

Consequences of global warming: Global warming would have the following effects:

- (i) Rise in sea level: Although the temperature increase of 1 to 3°C may seem insignificant, it is actually large enough to disrupt the delicate thermal balance on the earth and could cause glaciers and ice caps to melt. Consequently, the sea level would increase. It has been estimated that the, sea level may rise 0.5 to 1.5 m in the next 50 to 100 years. Higher sea level would:
  - (a) increase the frequency and severity of floods
  - (b) damage coastal areas, *i.e.*, low lying areas would submerge
  - (c) cause loss of soil replenishment
  - (d) cause sea water intrusion into river and other aquatic systems near the oceans.

One third population of the world lives in low lying areas near the coasts. A large part of the population of some countries is at risk if sea level rises substantially.

- (ii) Evaporation of water from aquatic systems: Global warming will cause more water to evaporate from aquatic systems and increase the concentration of water vapour in the atmosphere. The extra water vapours will amplify warming because water vapours itself is a greenhouse gas.
- (iii) Changing patterns of rainfall: Patterns of rainfall would change worldwise causing large shifts in agriculturally productive areas.
- (iv) Effect on plants: Most plants record an increase in photosynthesis only initially when the concentration of CO<sub>2</sub> is high. But this trend tends to fall with time. It has been observed that plants grown in higher concentration of CO<sub>2</sub> have less nitrogen and more carbon content. The dead material of such plants do not provide nitrogen-based nutrients to plants and therefore, fail to increase soil fertility. Due to increase in temperature, the moisture content of soil would decrease, and thus reducing the fertility of the soil.

(v) Effect on human health and wild life: An increase in global temperature is likely to increase the occurrence of infectious diseases such as malaria, dengue, yellow fever, sleeping sickness, etc. Likewise, the population of mosquitoes, flies, snails will increase and these can be responsible for the outbreak of cholera, pneumonic plague, etc. Greenhouse effect shall seriously disturb wild life. With every rise of 1°C, plant and tree species will have to move 90 km polewards to survive. As trees and plants die out and habitats disappear, so will the animals that depend on them.

Steps to minimise greenhouse effect: (i) To combat greenhouse effect, the emission of carbon dioxide must be reduced. This can be done by improving energy efficiency in automobiles, household heating and lighting. Non-fossil fuel energy sources such as solar energy, wind energy, photovoltaic cells, etc., should be encouraged.

Worldwide, one-third of all carbon dioxide emissions come from thermal electric generating plants. This carbon dioxide can be injected into the ocean at depths below 500 m so that its chances of being released to the atmosphere are almost negligible. Recently, a process has been devised to convert CO<sub>2</sub> into fuel. It has been found that CO<sub>2</sub> reacts with water at 50°C in presence of TiO<sub>2</sub> as a catalyst and ultraviolet light to give methane, hydrogen and carbon monoxide. All of these products can be used as fuels.

- (ii) The production and use of chlorofluorocarbons must be banned. The phasing out of CFCs will help to slow down the warming effect. Other efforts, such as recovery of methane gas generated at landfills and the reduction of natural gas leakages, should be made.
- (iii) There should be a global effort to prevent the massive deforestation. Vegetation plays a vital role in maintaining the steady-state concentration of carbon dioxide in the atmosphere. Converting the forests to farmlands for crops and grasslands for cattle may do irreparable damage to the delicate ecosystem and permanently alter the climate pattern on earth. Thus, deforestation can be reduced by preserving the existing forests and growing more trees.
- (iv) The world's population, which at present is increasing at an alarming rate, must be stabilised. Many of our environmental problems are related to the expanding human population. The check on population is essential to stabilise the atmospheric burden of greenhouse gases.

# 19.10 OZONE LAYER AND ITS DEPLETION (STRATOSPHERIC POLLUTION)

The ozone layer in the stratosphere is a natural feature of the earth's environment. This layer exists between 20 and 35 km above the earth's surface. The layer shields the earth from the harmful ultraviolet radiation of the sun. In recent years, however, human activities have disturbed the ozone layer through an increase in the global concentrations of some atmospheric chemicals. A depletion of ozone layer is considered as a serious

threat to all forms of life. A 5% decrease in ozone concentration could increase the incidence of skin cancer by 20%. Ultraviolet radiation is also a factor in diseases of the eye, including cataract formation. It can cause genetic mutations and destory crops and other forms of vegetation.

UV-radiations between 180 nm to 360 nm coming from the sun are prevented by the ozone layer to reach the earth's surface. A photon with a wavelength between 180 and 240 nm breaks the  $O_2$  molecule into two atoms of oxygen.

$$O_2 + hv_{(\lambda=180 - 240 \text{ nm})} \longrightarrow O + O$$
 ....(i)

An oxygen molecule captures one of these oxygen atoms to form an ozone molecule.

$$M + O_2 + O \longrightarrow M^* + O_3 + \text{Heat.}$$
 ....(ii)

The second step occurs twice for each  $O_2$  fragmentation, giving the overall balanced process of ozone formation:

$$3O_2 + hv \longrightarrow 2O_3 + \text{Heat.}$$
 ....(iii)

The production of ozone is required both as a source of oxygen atoms and frequent collisions between the atoms and the molecules that make up the atmosphere. A high fraction of the atmosphere is oxygen atoms at high altitudes, but not enough collisions occur to form ozone in significant amounts. This is because at this altitude the pressure, the molecular density and the rate of molecular collisions are very low. Below 20 km, on the other hand, all the light energetic enough to split oxygen molecules into oxygen atoms has already been absorbed. Consequently, below this altitude, insufficient oxygen atoms are present to generate ozone. Therefore the ozone layer is between 20 km and 35 km above the earth's surface.

The formation of  $O_3$  goes on continuously, but  $O_3$  is also decomposed by UV-radiation between 240 and 360 nm.

$$O_3 + hv_{(\lambda = 240 - 360 \text{ nm})} \longrightarrow O_2 + O$$
 ....(iv)

The O atom can react with a second  $O_3$  molecule.

$$O + O_3 \longrightarrow 2O_2$$
 ....(v)

Net reaction

$$2O_3 \longrightarrow 3O_2$$
 ....(vi)

Short-wavelength UV-light forms O<sub>3</sub>. whereas long-wavelength UV-light decomposes O<sub>3</sub>. The reactions form a delicate balance in which the rate of O<sub>3</sub> decomposition matches the rate of O<sub>3</sub> formation, *i.e.*, a dynamic equilibrium exists and maintains a constant concentration of O<sub>3</sub>. Thus, the ozone layer absorbs nearly all the solar photons in the range 180 nm to 360 nm, *i.e.*, 90 to 95% energetic UV-radiation and protects life on earth.

#### Ozone Depletion

There has been much hue and cry about the destruction of stratospheric ozone and the issue has assumed global dimensions. Two scientists, who first suggested in 1974 that CFCs could deplete the ozone layer, **F. Sherwood Rowland** 

and **Mario Molina**, won the 1995 Nobel Prize in chemistry, along with **Paul Crutzen**, who suggested that oxides of nitrogen in the atmosphere could catalyse the decomposition of ozone.

(i) Ozone depletion by oxides of nitrogen: Over the past few years, the concentration of nitrous oxide has increased considerably in the atmosphere. This has been attributed to large scale combustion of fossil fuels and enhanced use of nitrogen fertilizers. Nitrous oxide and other oxides of nitrogen are also emitted by supersonic transport aircrafts. Though nitrous oxide is quite inert in the stratosphere, it is photochemically converted into more reactive nitric oxide.

$$N_2O + hv \longrightarrow NO + N$$
 ... (vii) ·

The nitric oxide so formed then undergoes the following chain reactions.

$$NO + O_3 \longrightarrow NO_2 + O_2$$
 ... (viii)

$$O_3 + hv \longrightarrow O_2 + O$$
 ... (ix)

$$NO_2 + O \longrightarrow NO + O_2$$
 ... (x)

Net reaction:  $2O_3 + h\nu \longrightarrow 3O_2$ 

Thus, in the presence of oxides of nitrogen in the stratosphere, the decomposition rate of  $O_3$  increases.

(ii) Ozone depletion by chlorofluorocarbons (CFCs) : Since the mid-1970s scientists have been concerned about the harmful effects of certain chlorofluorocarbons on the ozone layer. The CFCs which are generally called by the trade name Freons were first synthesised in 1930. Some of the common ones are CFCl<sub>3</sub> (Freon-11), CF<sub>2</sub>Cl<sub>2</sub> (Freon-12), C<sub>2</sub>F<sub>3</sub>Cl<sub>3</sub> (Freon-113) and C<sub>2</sub>F<sub>4</sub>Cl<sub>2</sub> (Freon-114). Because these compounds are readily liquefied, relatively inert, non-toxic, non-combustible and volatile. They have been used as coolants in refrigerators and air-conditioners. Large quantities of CFCs are also used in the manufacture of disposable foam products such as cups and plates, propellants and as solvents to clean newly soldered electronic circuits. Most of the CFCs used for commercial and industrial purpose are eventually discharged into the atmosphere. Because CFCs are highly resistant to chemical attack, they are very stable in the lower atmosphere, where they can exist for upto 100 years. This stability gives CFCs time to diffuse up through the troposphere into the stratosphere. There, CFCs absorb wavelengths between 175 nm and 220 nm that break carbon-chlorine bonds and produce chlorine atoms.

$$CF_2Cl_2 \xrightarrow{h\nu} CF_2Cl + Cl$$
 ... (xi)

$$CFCl_3 \xrightarrow{h\nu} CFCl_2 + Cl$$
 ... (xii)

The reactive chlorine atoms then undergo the following reactions.

$$Cl + O_3 \longrightarrow ClO + O_2$$
 ... (xiii)  
 $ClO + O \longrightarrow Cl + O_2$ 

Net Reaction :  $O_3 + O \xrightarrow{Cl} 2O_2$ 

<sup>\*</sup>M is an inert substance such as  $N_2$ . The role of M in this exothermic reaction is to absorb some of the excess energy released and prevent the spontaneous decomposition of ozone molecule.

The oxygen atoms in equation (xiii) are provided by the photochemical decomposition of molecular oxygen and ozone. In this mechanism, chlorine atoms catalyse ozone decomposition. One chlorine atom can destroy upto  $100,000 \, O_3$  molecules before it is removed by some other reaction. The above mechanism for the destruction of  $O_3$  has been supported by the detection of ClO in the stratosphere in recent years.

The catalysed decomposition of ozone is known to be responsible for the ozone hole that develops in **Antarctica** each year in September and October, at the end of winter in the southern hemisphere. No ozone is generated during the long, dark Antarctic winter. Meanwhile, a heterogeneous reaction occurring on clouds of ice crystals at -85°C produces species such as Cl<sub>2</sub>, Br<sub>2</sub> and HOCl.

$$CIO + NO_2 \longrightarrow CIONO_2$$
  
 $CIO + CH_4 \longrightarrow CH_3 + HCI$   
 $CIONO_2 + H_2O \longrightarrow HOC1 + HNO_3$   
 $CIONO_2 + HCI \longrightarrow Cl_2 + HNO_3$ 

When the sun reappears in September, these molecules decompose photochemically to form Cl or Br atoms.

$$HOCl \xrightarrow{h\nu} OH + Cl$$

$$Cl_2 \xrightarrow{h\nu} 2Cl$$

The reactive chlorine atoms are thus rendered free to deplete ozone. Ozone depletion is by no means restricted to the southern hemisphere. In the extremely cold winter of 1994–95, a similar 'ozone hole' was found in the Arctic. Beyond that, the concentration of ozone in the atmosphere over parts of Siberia dropped by 40%.

In 1987, an international treaty was signed in Montreal to cut back on the use of CFCs. Production of freon in the United States was stopped in 1996. If all the nations comply with the agreement, the amount of CFCs which was at the maximum level around the year 2000, will be slowly declining over the present century.

An intense effort is under way to find substitutes that are not harmful to the ozone layer. One of the promising substances is hydrochlorofluorocarbon-123 (CF<sub>3</sub>CHCl<sub>2</sub>). The presence of hydrogen atom makes the compound more susceptible to oxidation in the lower atmosphere, so that it never reaches the stratosphere. Unfortunately, the same hydrogen atom also makes the compound more active biologically than CFCs. It can cause tumours in rats, although its toxic effect on humans is not known.

#### Effects of Depletion of the Ozone Layer

(i) Depletion of ozone layer is a serious threat to mankind. On account of low concentration of ozone in the stratosphere, more UV-radiation enters into troposphere. UV-radiations lead to ageing of skin, cataract or blindness, sunburn, skin cancer, etc., UV-radiations can damage the immune system which may lead to increased viral infections.

- (ii) UV-radiations damage the plant proteins and chlorophyll. This leads to harmful mutation of cells. It also increases evaporation of surface water through the stomata of leaves and decreases moisture content of soil.
- (iii) Aquatic animals and aquatic plants are greatly affected by UV-radiations. Excessive exposure to radiations may kill many phytoplanktons and damage the fish productivity.
- (iv) Ozone depletion has a very strong effect on climate and ecology.
- (v) UV-radiations damage paints, fibres, etc.

#### **Global Warming and Ozone Depletion**

Global warming and ozone depletion are important environmental issues that involve the atmosphere. There are enough differences between the two phenomena which have been tabulated below:

	Global warming	Ozone depletion
Region of atmos- phere involved	Mostly troposphere	Stratosphere
Major substances involved	CO <sub>2</sub> , CH <sub>4</sub> , H <sub>2</sub> O, N <sub>2</sub> O	O <sub>3</sub> , O <sub>2</sub> , CFCs
Interaction with radiation	IR-radiation absorbed by molecules which vibrate and re-emits energy to earth	UV-radiation absorbed by molecules which are dissociated into smaller fragments
Nature of problem	Increasing concentrations of greenhouse gases are apparently increasing average global temperature	Decreasing concentration of O <sub>3</sub> is apparently increasing exposure to UV-radiation
Source of problem	Release of CO <sub>2</sub> from burning fossil fuels, deforestation	Release of CFCs
Possible consequences	Climate change; increase in sea level, change in agricultural productivity	Skin and eye diseases; growth of plants affected
Possible responses	Check deforestation and less use of fossil fuels	Production and use of CFCs be completely stopped

#### 19.14 WATER POLLUTION

Next to air, water is the important constituent of life-support systems. Water is the most important natural resource. 80% of the earth's area is occupied by water. However, hardly 2.5% makes up the total world's supply of fresh water including the frozen water in the polar ice caps and glaciers. Water is needed for irrigation, industry, domestic needs, shipping and for sanitation and disposal of waste. The conservation and keeping up of a good supply of water is thus very essential. Man has however, polluted much of this limited supply of water by industrial wastes, sewage and a number of synthetic chemicals. Many rivers of the world receive heavy flux of sewage, domestic waste, industrial effluents, agricultural wastes, etc., which

contain substances varying from simple nutrients to highly toxic materials. In our country, all the major rivers have been polluted. These have actually become an unending sewer fit only to carry urban liquid waste, half burnt dead bodies, pesticides and other wastes. Many of our lakes have become dark with foul smell. Moreover, the rainfall on its way down to the earth brings down the air pollutants. Polluted water is the water which has more negative qualities than it has positive ones, *i.e.*, it is no longer fit for any use.

Water pollution is the presence of any foreign substance (organic, inorganic, radioactive or biological) in water which tends to degrade the quality so as to constitute a hazard or impair the usefulness of water.

The common water pollutants are:

- (i) Oxygen-demanding wastes
- (ii) Disease causing agents
- (iii) Synthetic organic compounds
- (iv) Plant nutrients
- (v) Inorganic chemicals and minerals.
- (vi) Suspended solids
- (vii) Radioactive substances
- (viii) Thermal discharges
- (ix) Oil

(i) Oxygen-demanding wastes: Dissolved oxygen (DO) is essential for sustaining animal and plant life in any aquatic system. If the DO level in water decreases, the aquatic organisms may not survive. The wastes such as domestic, industrial and biodegradable organic compounds are oxygen demanding wastes, These are decomposed by the bacterial population which in turn decreases the oxygen from water.

BOD (biochemical oxygen demand) is a measure of the oxygen utilised by microorganisms during oxidation of organic materials. It is the most widely known measure for assessing the water pollution potential of a given organic waste. BOD is directly proportional to the amount of organic waste which is to be broken down.

The determination of BOD of a sample of water requires 20–30 days for the complete decomposition of organic waste present in the sample. This is too long time for obtaining data. Therefore, the time has been fixed as five days, *i.e.*, BOD is the amount of oxygen consumed in five days. The measurement is done at 20°C. The sample of water is saturated with oxygen. It is then incubated for five days at 20°C. Microorganisms utilise oxygen to oxidise the waste during this period. The remaining oxygen is

measured and subtracted from the amount of oxygen originally present to get the BOD value. It is expressed in ppm.

BOD is a real measure of water quality. Clean water has a BOD value of less than 5 ppm. The polluted river water could have a BOD value of 17 ppm or more. The untreated municipal sewage has BOD value of 100–400 ppm.

**Chemical oxygen demand (COD):** It is another important water quality parameter. It is an index of the waste (organic and inorganic) of water which can be oxidised by a strong oxidising agent usually acidified potassium dichromate, K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>. This reagent oxidises most of the substances present in water including those which are not oxidised by micro-organisms.

The water sample is treated with a known amount of acidic potassium dichromate solution. The unreacted potassium dichromate is determined by back titration with a suitable reducing agent like Mohr's salt. From the amount of  $K_2Cr_2O_7$  consumed, the amount of oxygen utilised in the oxidation of water sample can be calculated, with the help of following oxygen.

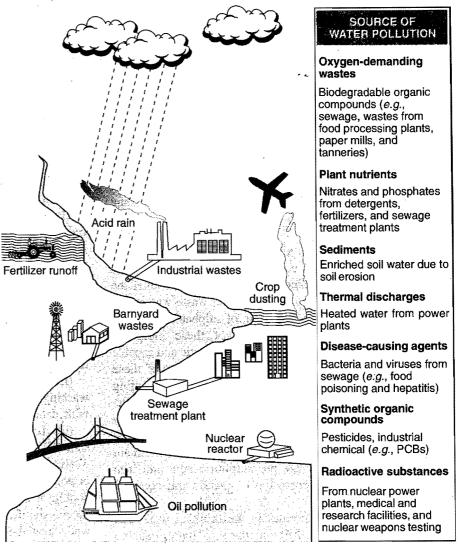

Fig. 19.9 Sources of water pollution

$$K_2Cr_2O_7 + 4H_2SO_4 \longrightarrow K_2SO_4 + Cr_2(SO_4)_3 + 4H_2O + 3[O]$$

COD is also expressed in ppm. COD values do not necessarily match the BOD values. Textile wastes, paper mill wastes, etc., with high cellulose content have COD values considerably higher than BOD values as cellulose is not readily attacked by dissolved oxygen.

- (ii) Disease causing agents: These are the various pathogenic micro-organisms which may enter the water along with sewage or other wastes. These microbes, mainly bacteria and viruses, can cause various diseases such as cholera, typhoid, dysentry, gastroenteritis, polio, hepatitis, etc.
- (iii) Synthetic organic compounds: These include pesticides, detergents and other industrial chemicals. These chemicals when present in water can act as toxic poisons for plants, animals and humans. These chemicals enter the hydrosphere either by losses during their transport and usage or by accidental or intentional disposal of wastes from manufacturing units.

Polychlorinated biphenyls (PCBs), having high stabilities, are relatively new additions to the list of pollutants of water. They are used as fluids in transformers and capacitors. The presence of these PCBs in water causes skin disorders in humans. These act as carcinogenic.

- (iv) Plant nutrients: Nitrogen and phosphorus fertilizers which are drained from agricultural lands or from other sources into water bodies may stimulate the growth of algae and aquatic weeds. The excessive growth of algae and aquatic plants due to added nutrients is called Eutrophication. The anaerobic conditions created by the rotting algae can present a health hazard for birds, fish and other aquatic species. During the decomposition of aquatic plants by micro-organisms, the amount of dissolved oxygen decreases which proves fatal for aquatic species.
- (v) Inorganic chemicals and minerals: These include various metals and metallic compounds released from human activities or from natural minerals. These pollutants enter the water bodies from municipal and industrial waste waters and mine run-off. The acid-rain consisting of sulphate and nitrate ions makes the water acidic. Most of these inorganic compounds, particularly of heavy metals, are toxic and capable of killing living organisms in water bodies. Most of these substances produce physiological poisoning by becoming attached to the tissues of aquatic organisms and accumulate. The metals of concern are cadmium, chromium, lead, mercury and silver. Alkalies discharged by industries such as textiles, tanneries, paper, etc., can also destroy aquatic life. The main constituents of mine drainage are sulphuric acid and iron compounds. These cause corrosion of metals and concrete and are fatal to fish.

Recently the level of fluorides in the drinking water has considerably increased in different parts of India, causing **fluorosis** (an incurable bone disease).

- (vi) Suspended solids: Suspended solids in water are mainly of sand, silt and minerals eroded from the land. Solid particles settle in reservoirs and dams and thus reduce their water storage capacity. The suspended particles in water bodies also block the sunlight required for the photosynthesis by bottom vegetation and thus reduce the availability of food to fishes.
- (vii) Radioactive substances: The refining of uranium ore is an important source of radioactive waste producing radioactive materials containing radium, bismuth, etc., which are a hazard in drinking waters. Certain marine organisms have the capacity for accumulating radio nucleides from water. These may cause radioactivity in living organisms. Radioactive substances can enter humans through food and water. These may get accumulated in blood and certain vital organs such as liver, thyroid gland, bone and muscular tissues.
- (viii) Thermal discharges: Power plants and industries use large quantities of water for cooling purposes. Used water is usually discharged directly into water bodies. The temperature of water bodies thus increases. This brings down the DO level which is harmful for micro-organisms. An increase in temperature also increases the toxicity of some chemical pollutants. Poisons are more toxic in summer months.
- (ix) Oil: Oil and oil wastes enter rivers and other water bodies from several sources like oil refineries, storage tanks, automobile waste oil, petro-chemical plants and industrial effluents. Normal tanker operations and spillage from oil tanker accidents cause marine pollution and shore contamination.

Since oil is insoluble in water, it floats and spreads rapidly into a thin layer. At sea, the oil layer is responsible for the death of birds. The oil penetrates the birds' feathers thereby affecting their insulation and buoyancy. The birds experience difficulty in floating and flying. The oil layer on the surface of water reduces the DO levels in water as oxygen transfer from atmosphere is prevented. Oil may be driven to shores through wind and tides where it is accumulated and posses aesthetic problems.

#### **Control of Water Pollution**

- (i) Septic tanks should be used for each house. This will reduce the flow of municipal sewage and human excreta towards river, lake or pool.
- (ii) Rivers, lakes, etc., should not be used for bathing and washing purposes. In this way, water sources are not polluted with detergents and germs.
- (iii) Too much use of pesticides which are not degradable should be avoided. These are highly toxic substances.
- (iv) Efforts should be made to increase the use of low grade or polluted water. Treatment of domestic sewage for industrial cooling is a good example of efficient use. Water reuse has a special significance in mining and similar industries where the water availability is less. These efforts will save fresh water from being polluted.

Environmental Chemistry 953

(v) Waste water treatment techniques should be applied before the polluted water enters a river, lake or pool. Available waste water treatment processes can be physical, chemical or biological. Physical processes comprise screening, sedimentation, floatation and filtration. Commonly used chemical processes are precipitation, coagulation and disinfection while biological processes are biological filtration and the activated sludge process. In particular cases, the processes such as carbon adsorption, oxidation and reduction, ion-exchange, reverse osmosis, electrolysis, etc., are also used.

# Water Quality Parameters (International standards for drinking water)

The quality of water is of vital concern for mankind as impure water can cause serious diseases. The following parameters must be followed before water is supplied for drinking purposes.

- It should be colourless and free from any odour or smell.
- (ii) It should be clear and free from suspended particles and turbidity. The turbidity should be less than 10 ppm.
- (iii) It should not be too acidic or too alkaline. The pH should lie between 5.5 to 9.5.
- (iv) It should be decent in taste. It can have some harmless salts for giving good taste. The total dissolved salts should not be more than 500 ppm.
- (v) It should be free from micro-organisms causing diseases.
- (vi) It should be free from harmful chemicals and should be reasonably soft.
- (vii) It should have dissolved oxygen 4-6 ppm.
- (viii) It should have specific conductance of  $300~\mu$  mho cm<sup>-1</sup>. Some international standards have been laid down for the drinking water. The chemicals that are allowed to be present and their tolerable limits permitted and some other conditions which must be satisfied for drinking water are briefly discussed below:
- (i) Fluoride: Water should be tested for fluoride ion concentration. Its deficiency is harmful as it causes tooth decay. Soluble fluoride is usually added to drinking water as to make its concentration upto 1 ppm or 1 mg dm<sup>-3</sup>. The F<sup>-</sup> ions make the enamel on the teeth much harder by changing hydroxyapatite, [3Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>·Ca(OH)<sub>2</sub>] into fluorapatite [3Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>·CaF<sub>2</sub>] which is much harder. However, brown mottling of teeth occurs if F<sup>-</sup> ion concentration exceeds 2 ppm. Higher concentrations (about 10 ppm) of F<sup>-</sup> ions are dangerous and cause harmful effects to teeth and bones.
- (ii) Lead: Lead pipes are used for water transport. If the water is comparatively acidic, lead salts come into water and get contaminated. The limit for the contamination of lead ions in drinking water is 50 ppb. Lead salts are slow poisons. They can damage liver, kidney and reproductive system, etc.
- (iii) Sulphate: At moderate concentrations of sulphate ions are harmless but excessive sulphate (> 500 ppm) in drinking water causes laxative effects and hypertension.

- (iv) Nitrate: The maximum limit of nitrate in drinking water is 50 ppm. Excessive concentration is harmful and can cause **methemoglobinemia** (blue baby syndrome).
- (v) Other metals: The recommended levels of some other metals in drinking water according to international standards are given in the following table:

#### Recommended Limits for Certain Substances in Drinking Water

	Contaminant	Permissible limit (ppm)
Chloride	(CI)	600
Cyanide	(CN <sup>-</sup> )	0.0001
Fluoride	(F <sup>-</sup> )	1–1.5
Nitrate + Nitrite	$(NO_3^- + NO_2^-)$	50
Phosphate	$(PO_4^{3-})$	0.1
Sulphate	$(SO_4^{2-})$	< 500
Arsenic	$(As^{3+})$	0.05
Chromium	$(Cr^{3+})$	0.05
Copper	(Cu <sup>2+</sup> )	3.0
Calcium	(Ca <sup>2+</sup> )	100
Magnesium	$(Mg^{2+})$	30
Barium	(Ba <sup>2+</sup> )	1.0
Iron	(Fe <sup>3+</sup> )	0.2
Lead	$(Pb^{2+})$	0.05
Zînc	$(Zn^{2+})$	5.0
Cadmium	$(Cd^{2+})$	0.005
Aluminium	$(Al^{3+})$	0.2
Manganese	$(Mn^{2+})$	0.05
Mercury	$(Hg^{2+})$	0.001
Pesticides		0.005

### 19.12 SOIL OR LAND POLLUTION

The soil or earth has been recognised as the mother of all plants, animals and human beings. It is very essential either directly or indirectly for the survival and maintenance of various biological species including man, as it produces food for all. The word soil is derived from a latin word *solum* meaning earthy materials in which plants grow. It is defined as a weathered layer of the earth's crust with living organisms and their products of decay. The chief components of the soil are inorganic matter (90–95%) and organic matter (5–10%). Besides, soil contains water and air. The composition of soil varies considerably from place to place.

Soil has become the dumping ground of most of waste products, *i.e.*, domestic, human, animal, industrial and agricultural. Every year the solid wastes dumped into the soil are increasing at an alarming rate all over the world. Different kinds of poisonous materials are being used these days and the whole earth is increasingly being poisoned and polluted as a consequence. The problem of soil pollution has aggravated by the use of agrochemicals such as pesticides, fungicides, insecticides, fertilizers and manures. Besides these, the soil is polluted by deadly pathogenic organisms.

Soil pollution is different from air and water pollution in the following respects:

- (i) Soil pollutants do not get dispersed unlike air and water pollutants. The pollution is localised unlike air and water pollution.
- (ii) The pollutants remain at a particular place for relatively longer periods.

#### Sources of Soil Pollution

The main sources of soil pollution are as follows:

- 1. Industrial wastes
- 2. Urban and domestic wastes
- 3. Agrochemicals
- 4. Soil erosion
- 5. Radioactive pollutants
- 6. Acid rain
- 1. Industrial wastes: Industrial wastes are the major cause of soil or land pollution. These wastes are mostly toxic due to the presence of cyanides, chromates, acids, alkalies, metals like nickel, cadmium, mercury, lead, etc. It is estimated about 50% of the raw materials used by the industries become waste products which are either thrown into water or dumped into the soil. The wastes are discharged from textile industry, paper and pulp industry, chemicals and drugs industry, soap and detergents industry, food processing industry, metal processing industries, glass, cement and engineering industries. The industrial wastes contain huge amounts of materials which are non-biodegradable and posing a serious threat to humanity.
- 2. Urban and domestic wastes: The urban and domestic wastes combined are referred as refuse. This comprises of garbage and waste materials like plastics, glass, metallic containers, fibres, papers and number of discarded products. The urban and domestic wastes are more harmful since most of these cannot be degraded easily. The wastes emit poisonous gases, toxic hydrocarbons and pathogenic microbes which cause diseases.
- **3. Agrochemicals:** The agrochemicals such as fertilizers, pesticides (insecticides, fungicides, herbicides), etc., are commonly used these days for agricultural crops. However, these find their way into food chain to be consumed by animals and humans and cause a number of health hazards.
- (a) Fertilizers: With the increase of population, there is an increasing demand of food. To enhance food production large quantities of fertilizers are being used.

No doubt, fertilizers certainly increase agricultural yield but their extensive use has adverse effects. Some adverse effects of fertilizers are: changes in mobility, status of nutrients in soil, stimulation of growth in crop fields and disturbance in ionic balance leading to high acidity, shortage of certain trace elements, etc. Excessive use of fertilizers results in the excessive growth of weeds and herbs.

Due to excessive amounts of nitrogen fertilizers, the concentration of nitrate ions increases in leafy vegetables.

Consumption of these vegetables results in bioaccumulation of nitrates in bodies. Nitrate by itself is not harmful but in human body it is reduced to nitrite which is responsible for occurrence of cancer.

**(b) Pesticides:** These are the chemicals which are used to save plants from pests, rats and parasitic fungi. Pesticides include **insecticides**, **fungicides** and **herbicides**. These substances cause soil pollution and adversely affect the health of animals and human beings.

According to a survey made by WHO, more than 50,000 people in developing countries are affected and poisoned annually and about 5000 die as a result of the effects of toxic agents used in agriculture. Samples of fruits, vegetables, milk and eggs from various parts of India showed that they contain pesticide residues much higher than human tolerance limits. Pesticides not only bring toxic effects on animals and human beings but also alter the fertility and decrease the soil respiration (root respiration and microbial respiration). Soil moisture has also been significantly reduced by pesticide application.

(i) Insecticides: These are the chemicals used to kill insects which damage the crops. After World War II, DDT was used in agriculture to control the damages caused by insects, rodents, weeds and various crop diseases. Other common examples of insecticides are BHC (benzene hexachloride), aldrin, dieldrin, etc. These insecticides are persistent in the environment and show biological activity for long periods of time. However, these insecticides not only kill unwanted insects but also target organisms which are helpful to crops. These insecticides keep on accumulating in the environment and cause pollution as being non-biodegradable. Their repeated use produces resistance in the pests. They are harmful to human beings and have been phased out. Consequently, a new series of insecticides, namely organophosphates, carbamates and pyrethroids have been introduced. Organophosphates and carbamates are biodegradable. But these are nerve toxins and are harmful to humans and have caused even deaths. Pyrethroids are neither presistent nor toxic, though costly.

It is not possible to ban the use of insecticides but the best option is to search for alternative insecticides which will kill pests but are friendly to environment.

- (ii) Fungicides: These are the chemicals which inhibit or prevent fungal growth or fungal diseases in plants or their seeds. Organomercury compounds are the most common fungicides. However, mercurial fungicides are responsible for human poisoning and deaths. The fungicides in the soil increase the number of harmful bacteria and decrease the population of useful types. For example, application of 4,6-dinitro-*o*-cresol and captan prevent nodule bacteria from initiating symbiotic nitrogen fixing process. The best fungicide available today is a derivative of β-methoxyacrylic acid.
- (iii) Herbicides: These are the chemicals used to control weeds. Some common weeds killers used earlier were inorganic compounds namely, sodium chlorate (NaClO<sub>3</sub>) and sodium

arsenite (Na<sub>3</sub>AsO<sub>3</sub>). However, their use has been restricted as they are toxic to mammals. These days, organic herbicides such as **triazines** are widely used.

- **4. Soil erosion:** Top soil is the most important as all agricultural activities depend on it. It is the vital component since all the nutrients required by plants are present here. At times, if it so happens that the top soil is dissipated by water or wind, the situation is termed **soil erosion.** Such soil becomes unsuitable for vegetation or agricultural production. Soil erosion is a natural process. It is caused by flow of water over the fields and by wind. The following factors influence the rate of soil erosion.
  - (a) Deforestation and loss of vegetation
  - (b) Cultivation on slopes of mountains
  - (c) Soils with low organic content.

Roots of grasses are an excellent binding material and keep the soil intact. Over-grazing, over-cropping and improper tilling accelerate soil erosion.

- 5. Radioactive pollutants: Radioactive wastes are produced in nuclear reactors, laboratories and hospitals. Nuclear explosions also produce a large number of radioactive wastes. Dumping of nuclear wastes is the biggest problem. From the soil, radioactive substances pass on to the human beings and animals in the form of food. The radioactive substances emit rays which are extremely harmful to human and animal cells.
- **6. Acid rain :** Acid rain disturbs the fertility of the soil. The activity of symbiotic nitrogen fixing bacteria present in the nodules of leguminous family is inhibited. The acid rain makes the soil acidic. This adversely affects the plants and animals. The acid rain contains H<sup>+</sup>, SO<sub>4</sub><sup>2-</sup> and NO<sub>3</sub> ions which leach the nutrients from the soil. Acid rain is responsible for damaging forests and other vegetations.

**Control of soil pollution:** The following steps have been suggested to control the soil pollution:

- (i) The use of chemical fertilizers can be reduced by applying biofertilizers and manures. Biological methods of pest control can also reduce the use of pesticides and thereby minimise soil pollution.
- (ii) Recycling and recovery of materials appears to be a reasonable solution for reducing soil pollution. Materials such as paper, glass and some kinds of plastics can be recycled. This would decrease the volume of refuse and help in the conservation of natural resources. For example, recovery of one tonne of paper can save 17 trees.
- (iii) Control of land loss can be attempted through restoring forest and grass cover to check soil erosion and floods. Crop rotation or mixed cropping can improve the fertility of the land.
- (iv) Proper methods should be adopted for the disposal of solid wastes. The simplest and most widely used technique of solid waste management is to bury the waste in locations situated away from residential areas. While adopting this practice, environmental and aesthetic considerations must be taken into consideration before selecting the dumping sites.

Acidic and alkaline wastes should be first neutralised, the insoluble material if biodegradable should be allowed to degrade under controlled conditions before their disposal. Incineration of wastes is expensive and leaves a huge residue and adds to air pollution. Pyrolysis, a process of combustion in absence of oxygen or the material burned under controlled atmosphere of oxygen, is an alternative to incineration. The gas and liquid thus obtained can be used as fuels. Pyrolysis of carbonaceous wastes, like firewood, coconut, palm waste, corn combs, cashew shell, rice husk, paddy straw and saw dust, yields charcoal along with products like tar, methyl alcohol, acetic acid, acetone and a fuel gas. Dung should be used to produce "gobar gas" and good manure through gobar gas plants.

## 19.13 STRATEGIES TO CONTROL ENVIRONMENTAL POLLUTION

Environmental pollution affects human beings, animals, plants as well as materials. It does not only slow down growth of plants or bring diseases to human beings and animals but can cause havoc. Every individual should be aware about dangers of environmental pollution and must try to minimise them by proper and scientific planning. If we do not act now, it is certain that not only this generation but the generations to come will suffer immeasurably. Following are some suggestions which can help to minimise pollution:

- (i) Population control is the foremost thing. Uncontrolled growth of population is the major threat to environment.
- (ii) Vegetation checks pollution. Forests should be maintained properly. Their areas should be increased. Green belts in cities (especially the industrial ones) should be developed.
- (iii) Non-conventional methods of producing energy should be developed. The use of fossil fuels should be reduced as far as possible.
- (iv) Proper sewage disposal plants and recovery of sewage water for various industrial and domestic purposes should be established.
- (v) Domestic garbage should be profitably utilised. Gobar gas plants in rural areas should be installed.
- (vi) Manures and biofertilizers should be used in place of chemical fertilizers.
- (vii) To reduce the volume of refuse, the recycling processes should be developed.
  - (viii) All types of nuclear tests must be stopped.
- (ix) The chimneys of industries should be placed at greater heights. These should be fitted with filters. The industrial wastes must be first treated to remove the hazardous materials before discharge.
- (x) There should be strict laws to prevent pollution. Heavy fines should be imposed on defaulters.

There are two types of wastes which are causing environmental pollution.

(a) Household waste which includes mainly sewage and municipal garbage.

(b) Industrial wastes include inorganic and organic suspended particles and inorganic and organic soluble matter. Some of them may be toxic in nature.

The proper disposal of these wastes can save the environment from pollution. Some of the methods which are usually employed for the disposal of these wastes are given below:

- 1. Recycling: This is the simplest method for waste disposal as a number of waste materials can be used as raw materials to manufacture of useful products again. Examples of recycling by industry are:
  - (i) The collection and recycling of glass
  - (ii) The use of scrap metal in the manufacture of steel
  - (iii) The recovery of energy from burning combustible waste.
- (iv) Due to recent developments, clothes will be made from recycled plastic waste.
  - (v) The use of waste paper.

Thus, recycling saves the cost of raw materials and converts waste into wealth.

- **2. Sewage treatment :** The treatment of sewage involves the following stages:
- (i) First stage involves the removal of large solid particles. This is done by mechanical process consisting of screening and sedimentation. The waste is filtered through different types of screens. The solids that are removed are disposed of in landfill sites.
- (ii) It is then allowed to flow into sedimentation tanks. This step allows the removal of solids that settle out (called **sludge**). This also allows the removal of grease which floats to the surface and can be skimmed off.
- (iii) Next stage involves the biological oxidation of organic content of waste materials by micro-organisms followed by filtration.
- (iv) In the final stage, some specialised physical and chemical processes are applied to remove the specific pollutants which are still present in order to improve the quality of waste water. The processes used are chemical removal of phosphate, coagulation, treatment with activated charcoal, disinfection by chlorine, reverse osmosis, filtration, etc.

Sludge is produced during above operations. It is dried and then may be incinerated, digested or dumped.

#### Incineration

It converts organic matter into CO<sub>2</sub> and H<sub>2</sub>O. It is used to destroy household waste, chemical waste and biological waste (e.g., from hospitals). A high temperature usually above 1273K and a plentiful oxygen supply is required. Exhaust gases must be filtered. The process leaves ash behind which is disposed of as landfill. The main disadvantage of this process is that it causes air pollution.

#### Digestion

The sewage sludge can undergo anaerobic digestion when micro-organisms degrade wastes in absence of oxygen. This process can also be applied to degrade a variety of toxic organic compounds. The overall process is the conversion of the organic materials into carbon dioxide and methane.

$$2(CH_2O) \longrightarrow CO_2 + CH_4$$

Methane may be used as a fuel.

#### Dumping

Dumping of the sewage sludge into sea has been very common. However, dumping of the sludge into land is increasing now-a-days. This is because it contains compounds of nitrogen and phosphorus which act as fertilizers for the soil.

# GREEN CHEMISTRY AS AN ALTERNATIVE TOOL FOR REDUCING POLLUTION

Over the past decade, an important initiative known as Green chemistry, the use of chemistry to prevent pollution, has been taken. "Green chemistry" can be defined as the design, development and implementation of chemical products and processes to reduce or eliminate the use and generation of substances hazardous to human health and environment. Green chemistry reduces pollution through fundamental break throughs in designing and redesigning chemical processes with an eye towards making them environmentally friendly, that is "benign by design". In this regard, Dr. Barry Trost advocates an 'atom economy' approach to the synthesis of commercial chemical products such as pharmaceutical, plastics and pesticides. Such synthesis would be designed so that all reactant atoms end up as desired products, and not as wasteful byproducts. This approach would save money as well as materials and undesired products would not be produced as waste which requires disposal. The reason green chemistry being adopted so rapidly around the world is because it is a pathway to ensuring economic and environmental prosperity.

The main objectives of green chemistry can be summarised in the following points:

- (i) It is better to prevent waste than to treat or clean up waste after it has been created.
- (ii) Synthetic methods should be designed to maximise the incorporation of all materials used in the process into the final product.
- (iii) Whenever practicable, synthetic methods should be designed to use and generate substances that possess little or no toxicity to human health and environment.
- (iv) Chemical products should be designed to affect their desired functions while minimising their toxicity.
- (v) The use of auxiliary substances (e.g., solvents, separation agents, etc.) should be made unnecessary wherever possible and innocuous when used.
- (vi) Energy requirements of chemical processes should be recognised for their environmental and economic impacts and should be minimised. If possible, synthetic methods should be conducted at ambient temperature and pressure.

- (vii) A raw material or feedstock should be renewable rather than depleting whenever technically and economically practicable.
- (viii) Unnecessary derivatization should be minimised or avoided if possible because such steps require additional reagents and can generate waste.
- (ix) Catalytic agents as selective as possible should be used.
- (x) Chemical products should be designed so that at the end of their function they break down into innocuous degradation products and do not persist in the environment.
- (xi) Substances and the form of a substance used in a chemical process should be chosen to minimise the potential for chemical accidents, including releases, explosions and fires.

Innovative "green" chemical methods already have made an impact on a wide variety of chemical manufacturing processes by decreasing or eliminating the use or creation of toxic substances. For example cheaper, less wasteful and less toxic methods have been developed to produce ibuprofen, pesticides, new materials for disposable diapers and contact lens, new drycleaning methods and recycled silicon wafer for integrated circuits. Some examples of green chemistry are given below:

- (i) Halons are greenhouse gas compounds composed of carbon, fluorine and bromine. These are used in fire fighting and other applications. Using a green chemistry approach, Pyrocool Technologies has synthesised a halon substitute. The product, called Pyrocool, is an environmentally benign foam that is more effective than halons in fire fighting, even large scale fires such as those on oil tankers and jet airplanes can be extinguished in a short time.
- (ii) Chlorofluorocarbons have been in use in refrigerators and air conditioning plants. However, these compounds have been found to be unfriendly to environment. These compounds are responsible for depletion of ozone layer in stratosphere and for global warming. Substitutes to these compounds such as HFC-134a (CF<sub>3</sub>·CH<sub>2</sub>F) have been discovered which are considered to be more friendly to environment.
- (iii) Solvents used to dryclean clothes are usually chlorinated compounds such as tetrachloroethylene C<sub>2</sub>Cl<sub>4</sub> which is a potential human carcinogen. These materials also have serious environmental consequences.

**Dr. Joe Desimone** has discovered a substitute for chlorinated compounds by synthesising cleaning detergents that work in liquid carbon dioxide. The detergents are such that one end of the molecule is soluble in non-polar substances like grease and oil stains, while the other end dissolves in liquid CO<sub>2</sub>. The breakthrough process is paving the way for designing replacements for conventional halogenated solvents currently used in manufacturing and in industries making coatings.

- (iv) Switching from air (78% nitrogen) to pure oxygen eliminates NO production and also saves fuel by more efficient burning. This has been achieved by glass manufacturers in the U.S.
- (v) Scientists are engineering biodegradability into some synthetic polymers. Certain bonds or groups are introduced into the molecules to make them susceptible to fungal or bacterial attack or to decomposition by moisture. Recently, a biodegradable polymer called Biomax has been developed which decomposes in about eight weeks in a landfill. Biomax could be used in a variety of applications such as lawnbags, bottles, liners of disposable diapers, disposable eating utensils and cups.
- (vi) The current commercial method for producing ibuprofen is a stunning application of green chemistry. Conventional methods of ibuprofen production required six steps, used large amounts of solvents and generated significant quantities of wastes. By using a catalyst that also serves as a solvent, BHC company has discovered a method of ibuprofen production in just three steps with a minimum of solvents and waste.
- (vii) Urea is a major fertilizer used worldwide. It provides nitrogen to soil by decomposing to ammonia and CO<sub>2</sub> when acted on by urease, an enzyme in soils. The ammonia is then taken up by plants.

$$NH_2CONH_2 + H_2O \xrightarrow{Urease} 2NH_3 + CO_2$$

However, the efficiency of urea as a fertilizer is reduced because of 30% ammonia is lost by evaporation before it can be taken up by plant roots. To overcome this loss, a formulation named **Agrotrain** has been developed which acts as urease inhibitor, *i.e.*, this formulation reduces the rate at which urease decomposes urea so that ammonia is released more slowly and efficiently.

## SOME SOLVED PROBLEYS

**Example 1.** Explain the tropospheric pollution in 100 words.

**Solution:** Troposphere is the lowest region of the atmosphere, *i.e.*, closest to the earth. It extends roughly to a height of about 11 km. It contains mainly nitrogen and oxygen. It also contains argon, carbon dioxide, water vapours, aerosols and traces of many other gases. The pollution of troposphere occurs due to the presence of undesirable gases and particulates. The main pollutant gases are:

- (i) Oxides of carbon (CO and CO<sub>2</sub>)—CO is a major pollutant.
- (ii) Oxides of sulphur (SO<sub>2</sub> and SO<sub>3</sub>)
- (iii) Oxides of nitrogen (NO and NO2)
- (iv) Hydrocarbons
- (v) Hydrogen sulphide (H<sub>2</sub>S), etc.

The particulate pollutants include dust, mist, fumes, smoke and aerosols.

**Example 2.** Carbon monoxide is more dangerous than carbon dioxide gas. Why?

**Solution:** Carbon monoxide is highly poisonous in nature. It combines readily with haemoglobin (it has 200 times more affinity than oxygen). Due to the formation of carboxy-haemoglobin, the quantity of oxygen to the body cells gets reduced, *i.e.*, CO reduces the oxygen carrying capacity of the blood and this leads to oxygen starvation (anoxia). The deficiency of oxygen produces headache, dizziness, choking, cardiac and pulmonary complications leading to paralysis and death.

CO<sub>2</sub> does not combine with haemoglobin. However, it is a greenhouse gas and helps in global warming. Hence, it is a less dangerous pollutant.

**Example 3.** Which gases are responsible for greenhouse effect? List some of them.

**Solution:** The gases which are transparent to sunlight and are capable of absorbing IR radiations and then re-emitting IR radiations of longer wavelengths are termed greenhouse gases. Some of these gases are: carbon dioxide; water vapours; oxides of nitrogen; methane; ozone; chlorofluorocarbons.

**Example 4.** Statues and monuments of India are affected by acid rain. How?

or

why is acid rain considered as a threat to Taj Mahal?

**Solution:** Taj Mahal (statues and monuments) is made of marble. The acid rain contains  $H_2SO_4$  which attacks the marble.

$$CaCO_3 + H_2SO_4 \longrightarrow CaSO_4 + H_2O + CO_2$$

As a result, the monuments (Taj Mahal) are being slowly corroded and the marble is getting discoloured and lustreless.

**Example 5.** What is smog? How are classical and photochemical smogs different?

**Solution:** Smog is a combination of smoke and fog. There are two types of smog:

- (a) Classical smog occurs in cool humid climate. It is a mixture of smoke, fog and sulphur dioxide. Chemically, it is a reducing mixture.
- (b) Photochemical smog occurs in warm, dry and sunny climate. It is formed by the action of sunlight on unsaturated hydrocarbons and nitrogen oxides. Chemically, it is an oxidising mixture. It does not involve any smoke or fog.

**Example 6.** Write down the reactions involved during the formation of photochemical smog.

**Solution :** Sunlight causes photochemical decomposition of NO<sub>2</sub>.

$$NO_2 + h\nu \longrightarrow NO + O$$

Atomic oxygen combines with molecular oxygen to form ozone.

$$O_2 + O + M \longrightarrow O_3 + M$$

*M* is an inert gas such as nitrogen. It takes up the excess energy. Ozone attacks the unsaturated hydrocarbon.

A second process involving hydrocarbons may be depicted as:

$$\begin{array}{c} \mathrm{NO_2} + hv \longrightarrow \mathrm{NO} + \mathrm{O} \\ \mathrm{O} + R\mathrm{H} \longrightarrow R^{\bullet} + R\mathrm{C}\mathring{\mathrm{O}} \\ R\mathrm{C}\mathring{\mathrm{O}} + \mathrm{O_2} \longrightarrow R\mathrm{C}\mathring{\mathrm{O}}_3 \\ R\mathrm{C}\mathring{\mathrm{O}}_3 + \mathrm{NO_2} \longrightarrow R\mathrm{CO}_3\mathrm{NO}_2 \end{array}$$

(peroxyacetyl nitrate, PAN)

The oxidation of hydrocarbons produces various organic intermediates which are less volatile. These substances condense into small droplets of liquid. The dispersion of these droplets in air forms smog. This reduces visibility and looks hazy.

**Example 7.** What are the reactions involved for ozone layer depletion in the atmosphere?

**Solution:** Two types of the compounds have been found responsible for destruction of ozone.

(i) Nitric oxide: Though, nitrous oxide is quite inert in the stratosphere, it is photochemically decomposed into more reactive nitric oxide.

$$N_2O + h\nu \longrightarrow NO + N$$

Nitric oxide, so formed, undergoes the following chain reactions:

$$\begin{array}{c}
NO + O_3 \longrightarrow NO_2 + O_2 \\
O_3 + hv \longrightarrow O_2 + O \\
NO_2 + O \longrightarrow NO + O_2 \\
\hline
2O_3 \longrightarrow 3O_2
\end{array}$$

Net reaction

Thus, in presence of oxides of nitrogen, the rate of decomposition of  $O_3$  increases.

(ii) Chlorofluorocarbons: Chlorofluorocarbons absorb wavelengths between 175 nm and 220 nm and produce chlorine atoms by breaking carbon-chlorine bonds.

$$CF_2Cl_2 + hv \longrightarrow CF_2Cl + Cl$$
  
 $CFCl_3 + hv \longrightarrow CFCl_2 + Cl$ 

Chlorine atoms undergo the following reactions:

$$\begin{array}{c}
\text{Cl} + \text{O}_3 \longrightarrow \text{ClO} + \text{O}_2 \\
\text{ClO} + \text{O} \longrightarrow \text{Cl} + \text{O}_2 \\
\hline
\text{O}_3 + \text{O} \stackrel{\text{Cl}}{\longrightarrow} 2\text{O}_2
\end{array}$$

Net reaction

Chlorine atoms catalyse the decomposition of O<sub>3</sub>.

**Example 8.** Answer the following questions:

- (i) What are viable and non-viable particulates?
- (ii) Fish do not grow as well in warm water as in cold water. Why?
  - (iii) What is pneumoconiosis? How does it occur?

**Solution:** (i) Viable particulates are living species such as bacteria, fungi, moulds, algae, etc. These are of small size.

Non-viable particulates are non-living which are formed by disintegration of large size materials or by condensation of small size particles or droplets. The examples are dust, mist, fume, smoke, etc.

- (ii) The amount of dissolved oxygen is less in warm water than cold water.
- (iii) Pneumoconiosis is a disease of lungs. It is caused by small sized particulates which enter into lung through nose and provide a large surface area for adsorption of carcinogenic compounds such as polynuclear hydrocarbons, asbestos, etc.

**Example 9.** What are the major causes of water pollution? Explain.

**Solution:** The main sources responsible for the pollution of water are:

- (a) Sewage and domestic wastes, e.g., human excreta, sewage, sludge, soaps and detergents, domestic wastes, etc.
- (b) **Industrial effluents:** These contain toxic chemicals and hazardous compounds both organic and inorganic.
- (c) Agricultural discharges: These include fertilizers, pesticides, insecticides, herbicides, etc.
- (d) **Thermal discharges:** Used water from power plants and industries is discharged directly into water bodies. The temperature of water bodies thus increases. This brings down DO level which is harmful for aquatic animals.
- (e) Oil: Oil and oil wastes enter rivers and other water bodies. Since oil is insoluble in water, it floats and spreads rapidly into a thin layer. This layer on the surface of water lowers DO level in water.

**Example 10.** (a) What do you mean by biochemical oxygen demand (BOD)?

(b) What is COD? Why is it preferred over BOD?

**Solution:** (a) The micro-organisms which decompose the organic matter present as waste in water need oxygen. The total amount of oxygen consumed by micro-organisms in decomposing the organic waste-present in a certain volume of a sample of water is called biochemical oxygen demand (BOD) of the water.

(b) The amount of oxygen consumed by all the pollutants measured by using a strong oxidising agent generally acidified  $K_2Cr_2O_7$  and expressed in ppm is called COD (chemical oxygen demand) of the given sample of water.

COD is preferred over BOD because the measurement of BOD takes a number of days (about 5 days) whereas COD can be determined in a very short time.

**Example 11.** (i) What would have happened if the greenhouse gases were totally missing in the earth's atmosphere? Discuss.

- (ii) What do you mean by green chemistry?
- (iii) How can domestic waste be used as manure?
- (iv) What are pesticides?
- (v) Explain the term "Eutrophication".

**Solution:** (i) The solar energy radiated back from the earth surface is absorbed by greenhouse gases which re-emit IR radiations or longer wavelengths. These radiations heat up the atmosphere near the earth's surface and keep it warm. If there were no greenhouse gases, the earth would be a very cold place and there would have no vegetation and life on earth.

- (ii) Green chemistry practices producing the chemicals of our daily use employing such reactions and chemical process which neither use toxic chemicals nor emit toxic chemicals into the atmosphere. This is the one way to protect our environment from chemical wastes.
- (iii) Domestic waste consists of two types of wastes, biodegradable and non-biodegradable. The biodegradable waste is separated and deposited in the landfills. With a passage of time, it is converted into manure consisting nitrogen and phosphorus compounds by micro-organisms.
- (iv) These are synthetic toxic chemical substances which are used in agriculture to control the damages done by insects, rodents, weeds and various crop diseases. The repeated use produces resistance in the pests and thus new substances are to be discovered in due course of time. DDT, BHC, aldrin and dieldrin have been tried as insectides. Now-a-days, organophosphates and carbamates have been in use as insectides.
- (v) The presence of excessive nutrients in a lake due to inflow of nutrients from fertilizers results in the increase of phosphate ions in water. As a result, the formation of algae is accelerated and the concentration of dissolved oxygen decreases. This process is called eutrophication. This badly affects the aquatic life.

## -•••- PRACTICE PROBLEMS -•••-

### ■ Subjective Type Questions

- 1. Name the four distinct regions of atmosphere.
- 2. Name the non-living components of environment.
- **3.** Name the zone of the atmosphere where ozone layer is present.
- 4. Name three greenhouse gases.
- 5. Define the term biosphere.
- **6.** What are the principal chemical species present in the stratosphere?
- 7. What is the wavelength range of the ultraviolet radiation which is removed in the stratosphere?
- 8. What is pollution?
- 9. What are pollutants?
- 10. What are primary pollutants? Give three examples.
- 11. What are secondary pollutants? Give three examples.
- 12. Name the main sources of air pollutants.
- 13. Name the two major man-made sources of oxides of nitrogen to the atmosphere.
- 14. Which oxide of nitrogen is a major concern as an air pollutant?
- 15. Which is the largest air pollutant in urban atmosphere?
- 16. Define photochemical oxidant.
- 17. Name two photochemical oxidants.
- 18. What is particulate?
- 19. Name four effects of air pollution.
- 20. What is acid rain?
- 21. Why is normal rain slightly acidic?
- 22. Name the two strong acids present in the acid rain.
- 23. What primary pollutants are responsible for photochemical smog?
- 24. Define greenhouse gases.
- 25. Select the gases which can absorb IR-radiation:
  Oxygen, carbon dioxide, methane, nitrogen, chlorofluorocarbons
- **26.** In the absence of greenhouse effect, what would be the mean temperature of the earth?
- 27. Define radiative forcing.
- **28.** What is the relative contribution of carbon dioxide to the greenhouse effect?
- 29. Suggest three ways to reduce greenhouse effect.
- **30.** Which substances are considered as responsible for the depletion of ozone layer?
- **31.** Name the regions of the atmosphere where global warming and ozone depletion phenomenon occur.
- 32. Define water pollution.
- 33. Name five common water pollutants.
- 34. Define green chemistry.
- 35. Give three suggestions for minimising pollution.
- **36.** Which of the following is more effective greenhouse gas: CO or H<sub>2</sub>O?

- 37. Which of the following gases qualify as greenhouse gases? CO, NO, NO<sub>2</sub>, Cl<sub>2</sub>, H<sub>2</sub>, Ne.
- 38. Which gas leaked to bring havoc in Bhopal tragedy?
- **39.** What is the compound formed when CO combines with haemoglobin?
- 40. What is anoxia?
- **41.** How are the flue gases from industries freed from oxides of nitrogen and sulphur?
- 42. What are asbestosis and silicosis?
- **43.** What is the composition of London smog?
- 44. What is the nature of classical smog?
- **45.** In which season and what time of the day, there is photochemical smog?
- **46.** Name two important sinks of CO<sub>2</sub>.
- **47.** What is humification?
- 48. Define pollution. Give its main causes.
- 49. What are the different air pollutants? Give their main sources.
- 50. Describe troposphere briefly.
- 51. Describe stratosphere briefly.
- Describe in short the various non-living components of environment.
- 53. Describe the main effects of air pollution.
- 54. How can air pollution be controlled?
- 55. Give the chemistry of acid rain. What are its effects?
- **56.** How has the ozone layer been affected by the oxides of nitrogen?
- **57.** Discuss in short the chemistry of the formation of photochemical smog.
- **58.** What is greenhouse effect? Which atmospheric gases are responsible for this effect?
- **59.** Write a short note on global warming:
  - (i) Name two common air pollutants.
  - (ii) Name two important sources of these pollutants.
  - (iii) Name one gas which causes greenhouse effect. What are the harmful consequences of this effect?

[I.S.C. 2000]

- **60.** Growth in human population has direct effect on pollution. Explain.
- **61.** Can pollution of the environment occur without human intervention? Explain.
- 62. Discuss water pollution. How can it be controlled?
- 63. Explain the main effects of water pollution.
- **64.** How does excessive use of pesticides and fertilizers in agriculture pollute our biosphere?
- **65.** What suggestions would you like to give to minimise pollution?
- **66.** How has the ozone layer been affected by the use of chlorofluorocarbons? What steps have been proposed to save the ozone layer?
- 67. Give three ways to prevent soil pollution.
- **68.** Define green chemistry. What are its objectives?

- **69.** Compare global warming phenomenon with ozone depletion phenomenon.
- **70.** Which one, carbon dioxide or carbon monoxide, is more toxic to human beings? Why?
- **71.** What are the harmful effects of photochemical smog and how can they be controlled?
- 72. What do you mean about ozone hole? What are its consequences?
- 73. A large number of fish are suddenly found floating dead on a lake. There is no evidence of toxic dumping but you find an abundance of phytoplankton. Suggest a reason for the fish kill.

[Hint: Quantity of dissolved oxygen decreases in water.]

- 74. Write short notes on the following:
  - (i) Primary and secondary pollutants
  - (ii) Biodegradable and non-biodegradable pollutants
  - (iii) Contaminant
- 75. How ozone layer is formed and acting as a protecting umbrella?
- **76.** Discuss the importance of dissolved oxygen in water. How is COD of a polluted water measured?
- 77. Name at least four soil pollutants. Explain one of them.
- 78. What are pesticides and herbicides? Explain giving examples.
- **79.** How should the management of domestic and industrial wastes be done?
- **80.** Define atmosphere. Give an account of the composition and structure of atmosphere.
- **81.** Define pollution. Give an account of environmental pollutants. Describe their sources and suggest suitable methods of control of air pollution.

- **82.** Is ozone useful or harmful to us? Discuss the chemistry of ozone depletion. Discuss also the threats to its depletion in atmosphere.
- 83. Write an essay on photochemical smog.
- 84. Write an essay on greenhouse effect and global warming.
- 85. What are the major sources of water pollution? Discuss the nature of the pollutants involved and suggest methods of control.
- 86. Write an essay on green chemistry.
- **87.** Do you observe any soil pollution in your neighbourhood? What efforts will you make for controlling the soil pollution?
- **88.** What do you mean by green chemistry? How it will help in decreasing environmental pollution?
- 89. What are international standards for drinking water?
- **90.** Explain the strategies which should be adopted to control environmental pollution.
- **91.** What do you understand by BOD and COD? How are these determined? Which one is preferred?

#### Matching Type Questions

#### Match the Column-I with Column-II:

	Column-I		Column-II
(a)	Greenhouse effect	(p)	Primary pollutant
(b)	Smoke	(q)	Non-Biodegradable
(c)	Nitric oxide	(r)	Photochemical oxidant
(d)	PAN	(s)	Bone disease
(e)	Fluorosis	(t)	Physical pollutant
(f)	Noise	(u)	Chlorofluorocarbons
(g)	Plastic	(v)	Global warming
(h)	Ozone depletion	. (w)	Particulate

### Answers

#### Answers: Subjective Type Questions

- 1. (a) Troposphere (b) Stratosphere (c) Mesosphere
  - (d) Thermosphere.
- 2. (a) Atmosphere (b) Hydrosphere (c) Lithosphere
- 3. Stratosphere
- 4. (i) Carbon dioxide (ii) water vapours (iii) nitrous oxide.
- The environment which supports life. It extends to about 20 km from the bottom of the ocean to the highest point in the atmosphere at which life can survive.
- 6.  $O_3$ ,  $O_2$ ,  $N_2$ , and some water vapours.
- Ultraviolet radiations between 190 to 340 nm are removed in the stratosphere.
- 8. Any undesirable change in the physical, chemical and biological characteristics of air, water and land which is harmful to man directly or indirectly is termed pollution.
- Pollutants are chemical, biological or physical agents that exert undesirable effects on living organisms including human health, environment or belongings.
- Primary pollutants are those which are emitted directly from the sources. The examples are: particulate matter, carbon monoxide, sulphur dioxide, nitric oxide, etc.
- 11. Secondary pollutants are those which are formed in the atmosphere by chemical interactions among primary pollutants and normal atmospheric constituents. The examples are: sulphur trioxide, nitrogen dioxide, PAN and PBN, etc.
- 12. (i) Combustion of fossil fuels such as coal, petroleum and natural gas.
  - (ii) Industrial processes
- (iii) Agricultural burning
- 13. (i) Fossil fuel based power plants (ii) Automobiles.
- **14.** Nitrogen dioxide **15.** Carbon monoxide
- 16. Photochemical oxidant is an atmospheric substance which is produced by a photochemical process which can oxidise materials not readily oxidised by oxygen. These are secondary pollutants.
- 17. Ozone, peroxy-acetyl nitrate.
- 18. Particulate refers to any atmospheric substance which is not in gaseous state. It can be a solid or a liquid or a mixture of the two.
- 19. (i) Harmful effects on human health
  - (ii) Harmful effects on vegetation
  - (iii) Damage to materials
- (iv) Climatic changes.

- **20.** It describes all precipitation-rain, snow, fog, dew-which is more acidic than normal rain, *i.e.*, pH is less than 5.6.
- 21. CO<sub>2</sub> on dissolution produces a weak carbonic acid.
- 22. Sulphuric acid (H<sub>2</sub>SO<sub>4</sub>) and nitric acid (HNO<sub>3</sub>).
- 23. Nitric oxide, carbon monoxide and various unburned hydrocarbons are the primary pollutants which are responsible for the formation of photochemical smog in presence of sunlight.
- 24. The gases which are transparent to sunlight and are capable of absorbing IR-radiation and then to re-emit IR-radiation of longer wavelengths are termed greenhouse gases.
- 25. Carbon dioxide, methane, chlorofluorocarbons.
- **26.** − 15°C
- **27.** The amount of warming which a greenhouse gas imparts to 1 square metre of the earth is called radiative forcing.
- **28.** 50%.
- 29. (i) Non-fossil energy sources should be adopted (ii) The production and use of chlorofluorocarbons should be banned (iii) Deforestation should be prevented (iv) Population of the world must be stabilised.
- 30. (i) Oxides of nitrogen (ii) Chlorofluorocarbons.
- 31. Global warming-Troposphere: Ozone depletion-Stratosphere.
- 32. See text
- (i) Oxygen demanding wastes (ii) Synthetic organic compounds (iii)
   Inorganic Chemistry and minerals (iv) Fertilizers (v) Sewage.
- 34. See text 35. See text
- **36.** H<sub>2</sub>O **37.** CO, NO and NO<sub>2</sub>
- 38. Methyl isocyanate
- 39. Carboxyhaemoglobin
- 40. Acute oxygen starvation in the body.
- By passing through alkaline solutions of Ca(OH)<sub>2</sub> and Mg(OH)<sub>2</sub> or through conc. H<sub>2</sub>SO<sub>4</sub>.
- **42.** The lung disease caused by particulates of asbestos and silica respectively.
- 43. Fog of H<sub>2</sub>SO<sub>4</sub> droplets deposited on carbon particulates.
- 44. Reducing 45. Summer, daytime (after noon)
- 46. Ocean, plants (photosynthesis)
- The decomposition of organic matter in the soil by micro-organisms to produce humus.

				(a) Deforestation	
	(d) Particulates refer to all atmospheric substances that a	re		(c) Increasing desert	
			19.	If BOD of river is high, it means that the river is:	
8.	Which one of the following is an invaluable source of energy	gy		(a) not polluted	
	but does not cause pollution?			(b) very much polluted with inorganic chemicals	
	(a) Petroleum			(c) very much polluted with organic chemicals which	are
				decomposed by micro-organisms	
9.	The acid rain possesses:			(d) polluted with pesticides	
			20.	Which of the following is produced by reaction of ultravi	olet
	( ) I	╸╽		light?	
10.	All except which cause pollution:			(a) CO $\square$ (b) SO <sub>2</sub>	
				(c) $O_3$	
	(-)		21.	Earth is protected from UV-radiations by:	_
11.	DDT is:	_		(a) ozone layer	
			22	(c) carbon dioxide	
			22.	Which air pollutant is not released by scooters and car	
	• •			(a) SO <sub>2</sub>	
	(d) dichlorodifluorotitanium			(c) Hydrocarbons	

23.	Photo-chemical oxidants such as PAN or PBN are formed:	35.	Ozone hole refers to:	
	(a) by action or nitrogen oxides on hydrocarbons in		(a) increased concentration of ozone	
	presence of sunlight	.	(b) reduction in the thickness of ozone layer in troposphere	
	(b) by action of carbon dioxide on hydrocarbons in			
	presence of sunlight	1	(c) reduction in the thickness of ozone layer in stratosphere	
	(c) by action of hydrogen sulphide on hydrocarbons in			
	presence of sunlight	İ	(d) hole in ozone layer	
	(d) none of these	36.		
24.		30.	of water over a period of time is done to find out:	
4 <b>4.</b>				
	(a) pesticides in water		(a) biogas generation	
	(b) fluorides in water		(b) biological oxygen demand	
	(c) carbon monoxide in air		(c) biosynthetic pathways	
	(d) sulphur dioxide in air	25	(d) fermentation	
25.	The pollutants released by jet aeroplanes in the atmosphere	37.	One of the metals used as a catalyst in automobiles' catalytic	
	as fluorocarbons are called:		converter is:	
	(a) photochemical oxidants		(a) palladium	
	(b) photochemical reductants	20	(c) radium	
	(c) aerosols	38.	Photochemical smog is related to the pollution of:	
	(d) physical pollutants		(a) soil	
26.	Pollution can be controlled by:	20.	(c) noise $\Box$ (d) air $\Box$	J
	(a) sewage treatment	39.	Lead is considered as:	
	(b) manufacturing electrically operated vehicles		(a) water pollutant	
	(c) adopting green chemistry	100	(c) air pollutant	J
	(d) all of the above	40.	Gas released during Bhopal tragedy was:	. 1
27.	The chief pollutants which are responsible for ozone		(a) sodium isothiocyanate	
	depletion:		(b) ethyl isothiocyanate	_
	(a) $SO_2$		(c) potassium isothiocyanate	
	(b) CO <sub>2</sub>		(d) methyl isothiocyanate	•
	(c) CO	41.	Pollutant is a chemical substance or factor which disturbs:	
	(d) oxides of nitrogen and chlorofluorocarbons		(a) our balanced environment	
28.	SO <sub>2</sub> and NO <sub>2</sub> cause pollution by increasing:	į	(b) geochemical cycles	
	(a) acidity	1.0	(c) flora of any region □ (d) fauna of any region □	i
••	(c) buffer action $\Box$ (d) none of these $\Box$	42.	A brick kiln should not be allowed near an orchard:	
29.	Taj Mahal is threatened due to effect of:		(a) to save plants from soil erosion	
	(a) chlorine	1	(b) to save fruits from labourers

## **Objective Questions for IIT ASPIRANTS**

- 1. Fluoride pollution mainly affects:
  - (a) teeth

(b) heart

(c) brain

- (d) kidney
- 2. In 1984, the Bhopal gas tragedy took place because methyl isocyanate:
  - (a) reacted with water
- (b) reacted with DDT
- (c) reacted with ammonia
- (d) reacted with CO<sub>2</sub>
- Maximum permissible limit of noise as per the noise pollution rules 2000 of India is:
  - (a) 75 decibel
- (b) 65 decibel
- (c) 55 decibel
- (d) 50 decibel
- Silicosis is caused by:
  - (a) acid rain
- (b) depletion of ozone
- (c) inhalation of aerosols
- (d) inhalation of sulphur dioxide
- Sterility is caused by which pollutant in water?
  - (a) copper
- (b) mercury.
- (c) cadmium
- (d) manganese
- The pH of acid rain water is:
  - (a) 1.2

(b) 3.1

(c) 5

- (d) 6
- Byssinosis; a disease is caused by:
  - (a) fly ash
- (b) cement dust
- (c) cotton fibres
- (d) lead particles
- 8. Major source of methane in India is:
  - (a) fruit orchards
- (b) sugar cane plantation
- (c) rice fields
- (d) wheat fields
- Which element is believed to be responsible for the fall of the Roman Empire?
  - (a) copper
- (b) lead
- (c) arsenic
- (d) zinc
- 10. Supersonic jets cause pollution by thinning of:
  - (a) CO<sub>2</sub> layer
- (b) SO<sub>2</sub> layer
- (c) O<sub>2</sub> layer
- (d) O<sub>3</sub> layer

- 11. Cracking of rubber is caused due to:
  - (a) acid rain
- (b) soot

(c) smog

- (d) all of these
- 12. Sulphur dioxide affects:
  - (a) cell wall
- (b) brain

(c) skin

(d) membrane system

- **13.** DDT is:
  - (a) greenhouse gas
- (b) degradable pollutant
- (c) non degradable pollutant (d) none of these
- 14. Ultraviolet radiations from sunlight causes a reaction that produces:
  - (a) fluorides
- (b) carbon monoxide
- (c) sulphur dioxide
- (d) ozone
- 15. Newspaper contains a toxic material called:
  - (a) cadmium
- (b) lead
- (c) manganese
- (d) mercury
- 16. Most atmospheric pollutants do not rise above:
  - (a) 6000 m
- (b) 600 m

(c) 60 km

- (d) 6 m
- 17. Jet aeroplanes release the pollutants in air called:
  - (a) smog

- (b) photochemical oxidants
- (c) aerosols
- (d) fly ash
- 18. Non-ionising radiations with specific biological effects are:
  - (a) UV radiations
- (b) Beta rays
- (c) Gamma rays
- (d) X-rays
- 19. Which of the following pollutants is not harmful to the lungs?
  - (a) CO

(b) SO<sub>2</sub>

- (d)  $NO_2$
- 20. Which of the following vehicular fuels is currently accepted as ecofriendly?
  - (a) Diesel

(b) Petrol

(c) LPG

(d) CNG

## Assertion-Reason Type Questions

In each of the following questions two statements are given as Assertion (A) and Reason (R). Mark the answer according to following instructions:

- (a) If both (A) and (R) are correct and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are correct and (R) is not the correct explanation of (A).
- (c) If (A) is correct but (R) is wrong.

- (d) If both (A) and (R) are wrong.
- 1. (A) DDT and BHC are non-biodegradable soil pollutants.
  - (R) DDT and BHC are fertilizers.
- 2. (A) PAN is main constituent of photochemical smog.
  - (R) It is formed by the action of oxides of nitrogen and hydrocarbons in presence of sunlight.
- 3. (A) Earth is protected from IR radiations by ozone layer.
  - (R) Ozone layer is present in troposphere of the atmosphere.

- **4.** (A) CO is a toxic air pollutant.
  - (R) CO binds with haemoglobin of blood and reduces oxygen transport efficiency of blood.
- 5. (A) Photochemical smog is produced by oxides of nitrogen.
- (R) Automobiles are a major source of oxides of nitrogen.
- 6. (A) For greenhouse effect, presence of green plants is essential.
  - (R) Greenhouse effect is responsible for global warming.

## THOUGHT TYPE QUESTIONS

#### THOUGHT 1

Nitric oxide (NO) is the nucleus of photochemical smog.

$$2NO(g) + O_2(air) \longrightarrow 2NO_2(g)$$

$$\begin{array}{c}
\text{NO}_2(g) \xrightarrow{\text{Sunlight}} & \text{NO}(g) + [O] \\
[O] + O_2(g) & \longrightarrow & O_3(g)
\end{array}$$

Both NO<sub>2</sub> and O<sub>3</sub> are strong oxidising agents and react with unburnt hydrocarbons in the polluted air to produce formaldehyde, acrolein and peroxyacetyl nitrate (PAN). These products are harmful to the plant and animal life.

Catalytic converters are now installed in the automobiles to reduce the photochemical smog. Photochemical smog can also be suppressed by certain compounds, which act as free radical trap.

- 1. Which are the primary constituents of photochemical smog?
  - (a) SO<sub>2</sub> and CO
- (b) NO<sub>2</sub> and hydrocarbons
- (c) CO<sub>2</sub> and NO<sub>2</sub>
- (d) Hydrocarbons and CFCs
- Photochemical transformation of the automobile exhaust emission in UV wavelength of sunlight results into:
  - (a)  $CH_4$  and  $C_6H_6$
- (b) O<sub>3</sub> and PAN
- (c) CO<sub>2</sub> and NO<sub>2</sub>
- (d) CO and CO2
- Smog is common pollutant in places having:
  - (a) high temperature
  - (b) low temperature
  - (c) excessive ammonia in the air
  - (d) excessive sulphur dioxide in the air
- 4. Photochemical smog formed in congested metropolitan cities mainly consist of:
  - (a) hydrocarbons, SO2 and CO2
  - (b) hydrocarbons, ozone and SO<sub>2</sub>
  - (c) ozone, peroxyacetyl nitrate and NO<sub>r</sub>
  - (d) smoke, peroxyacetyl nitrate and SO<sub>2</sub>

#### THOUGHT 2

Ozone layer acts as one of the most important life support system. The major cause of ozone layer destruction is believed to be the release of chlorofluorocarbon compounds. UV radiation causes the chlorofluorocarbons to dissociate:

$$CF_2Cl_2 \xrightarrow{h\nu} Cl^* + \overset{*}{C}F_2Cl$$

A highly reactive chlorine atom is responsible for the decomposition of ozone.

$$Cl^* + O_3 \longrightarrow ClO^* + O_2(g)$$
  
 $ClO^* + O(g) \longrightarrow Cl^* + O_2(g)$ 

Free radicals of chlorine decompose ozone molecules in a chain reaction. The depletion of ozone layer leading to ozone hole has, however, been mainly observed in the stratosphere over Antarctica. Special type of cloud called polar stratospheric clouds are formed over Antarctica. These clouds (contain solid HNO<sub>3</sub>·3H<sub>2</sub>O) play an important role in ozone depletion.

$$CIO^* + NO_2 \longrightarrow CIONO_2$$
  
 $CIONO_2 + H_2O \longrightarrow HOCl + HNO_3$   
 $CIONO_2 + HCl \longrightarrow Cl_2 + HNO_3$ 

$$HOCl \xrightarrow{h\nu} HO^* + Cl^*$$

The reactive chlorine atoms thus formed are rendered to deplete ozone layer.

- 1. The ozone layer is present in:
  - (a) troposphere
- (b) stratosphere
- (c) mesosphere
- (d) thermosphere
- The result of ozone hole is:
  - (a) acid rain
- (b) greenhouse effect
- (c) global warming
- (d) the UV radiation reach to earth
- 3. Freon is not recommended to be used in refrigerators because thev:
  - (a) increase temperature
- (b) deplete ozone
- (c) affect environment
- (d) affect human body
- Ozone in stratosphere is depleted by:
- [A.I.I.M.S. 2004]
- (a)  $C_6F_6$ (b)  $C_7F_{16}$ 
  - (c) CF<sub>2</sub>Cl<sub>2</sub> (d)  $C_6H_6Cl_6$
- 5. Peeling of ozone umbrella, which protects us from UV rays is caused by:
  - (a) PAN
- (b) CO<sub>2</sub>
- (c) CFCs
- (d) coal burning

Thought 1 1. (b) Thought 2

- **1.** (b)
- 2. (b) 2. (d)
- **3.** (a) 3. (b)

- 5. (c)

## MISCELLANEOUS .......

#### TYPE 1: Short and Very Short Questions

#### ACTION OF HEAT ON COMPOUNDS

- Q. 1. What happens when the following nitrates are heated?
  - (a) NaNO<sub>3</sub> (Chile saltpetre)
  - (b) KNO<sub>3</sub> (Nitre)
  - (c) AgNO<sub>3</sub> (Lunar caustic)
  - (d) Hg(NO<sub>3</sub>)<sub>2</sub> (Mercuric nitrate)
  - (e) NH<sub>4</sub>NO<sub>3</sub>

(d)

- (f) Nitrates of heavy metals like Cu, Zn, Pb, Ca and Ba.
- (g) LiNO<sub>3</sub> (Lithium nitrate) and Mg(NO<sub>3</sub>)<sub>2</sub> (magnesium nitrate).
- Ans. (a) At 316°C, it melts and decomposes to nitrite and oxygen on further heating.

$$2NaNO_3 \longrightarrow 2NaNO_2 + O_2$$

(b) KNO<sub>3</sub> melts at 336°C and decomposes like NaNO<sub>3</sub> on further heating.

$$2KNO_3 \longrightarrow 2KNO_2 + O_2$$

(c) Lunar caustic melts at 209°C. It decomposes on further heating according to the following chemical reactions:

$$2AgNO_3 \longrightarrow 2AgNO_2 + O_2$$
  
 $2AgNO_2 \longrightarrow 2Ag + 2NO_2$ 

- $Hg(NO_3)_2 \longrightarrow Hg + 2NO_2 + O_2$
- (e) NH<sub>4</sub>NO<sub>3</sub> melts at 165°C and decomposes at 200°C to give laughing gas. Above 260°C its reaction becomes explosive.

$$NH_4NO_3 \xrightarrow{\Delta} N_2O + 2H_2O$$

(f) Heavy metal nitrates decompose to give metal oxide along with  $NO_2$  and  $O_2$ .

$$2Zn(NO_3)_2 \xrightarrow{\Delta} 2ZnO + 4NO_2 + O_2$$

$$2Ba(NO_3)_2 \xrightarrow{\Delta} 2BaO + 4NO_2 + O_2$$

$$2Cu(NO_3)_2 \xrightarrow{\Delta} 2CuO + 4NO_2 + O_2$$

$$2Pb(NO_3)_2 \xrightarrow{\Delta} 2PbO + 4NO_2 + O_2$$

(g) Nitrates of lithium and magnesium decompose on heating giving mixture of nitrogen dioxide and oxygen.

$$4\text{LinO}_3 \longrightarrow 2\text{Li}_2\text{O} + 4\text{NO}_2 + \text{O}_2$$
  
 $2\text{Mg(NO}_3)_2 \longrightarrow 2\text{MgO} + 4\text{NO}_2 + \text{O}_2$ 

- Q. 2. What happens when the following carbonates are heated?
  - (a) Washing soda (Na<sub>2</sub>CO<sub>3</sub>·10H<sub>2</sub>O)
  - (b) Silver and mercury carbonate (Ag<sub>2</sub>CO<sub>3</sub>, Hg<sub>2</sub>CO<sub>3</sub>)
  - (c) Ammonium carbonate [(NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub>]
  - (d) Limestone (CaCO<sub>3</sub>)
  - (e) Basic copper carbonate [CuCO<sub>3</sub>·Cu(OH)<sub>2</sub>]
  - (f) Zinc carbonate (ZnCO<sub>3</sub>).
- Ans. (a) Dehydration takes place on heating the washing soda.

$$Na_2CO_3 \cdot 10H_2O \xrightarrow{\Delta} Na_2CO_3 \cdot H_2O$$
 (melts at 950°C)  
 $Na_2CO_3 \cdot H_2O \xrightarrow{\Delta} Na_2CO_3$  (anhydrous)

(b) Silver and mercury carbonates decompose on heating to corresponding metal.

$$\begin{array}{ccc}
2Ag_2CO_3 & \xrightarrow{\Delta} & 4Ag + 2CO_2 + O_2 \\
2Hg_2CO_3 & \xrightarrow{\Delta} & 4Hg + 2CO_2 + O_2
\end{array}$$

(c) Ammonium carbonate on heating changes to ammonium bicarbonate followed by ammonium carbamate.

$$2(NH_4)_2CO_3 \longrightarrow NH_4HCO_3 + NH_2COONH_4$$

carbamate

+ H<sub>2</sub>O + NH<sub>3</sub>

(d) Limestone decomposes on heating to evolve CO<sub>2</sub> gas, leaving behind CaO.

$$CaCO_3 \xrightarrow{\Delta} CaO + CO_2$$

(e) Carbonate of copper also decomposes like calcium carbonate.

$$CuCO_3 \cdot Cu(OH)_2 \xrightarrow{\Delta} 2CuO + CO_2 \uparrow + H_2O \uparrow$$

(f) At about 300°C, ZnCO<sub>3</sub> decomposes to give ZnO and CO<sub>2</sub> gas.

$$ZnCO_3 \xrightarrow{300^{\circ}C} ZnO + CO_2 \uparrow$$

Q. 3. What happens when bicarbonates of calcium and sodium are heated?

Ans. These bicarbonates decompose to give corresponding carbonates.

$$\begin{array}{ccc} \text{Ca(HCO}_3)_2 & \xrightarrow{\Delta} & \text{CaCO}_3 + \text{H}_2\text{O} + \text{CO}_2 \\ \text{2NaHCO}_3 & \xrightarrow{\Delta} & \text{Na}_2\text{CO}_3 + \text{H}_2\text{O} + \text{CO}_2 \end{array}$$

- **Q. 4.** What happens when sulphates of the following metals are heated?
  - (a) Sulphates of Na, K, Mg, Ca, Sr, Ba and Pb
  - (b) Sulphates of Ag, Cu, Zn and Fe
  - (c) Ammonium sulphate, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>.

Ans. (a) Sulphates of these metals lie in hydrated state; when they are heated, dehydration takes place.

$$\begin{array}{c} \text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O} & \longrightarrow & \text{Na}_2\text{SO}_4 + 10\text{H}_2\text{O} \\ \text{Glauber's salt} \\ \text{MgSO}_4 \cdot 7\text{H}_2\text{O} & \xrightarrow{150^\circ\text{C}} & \text{MgSO}_4 \cdot \text{H}_2\text{O} & \xrightarrow{200^\circ\text{C}} & \text{MgSO}_4 \\ \text{Epsom salt} \\ 2(\text{CaSO}_4 \cdot 2\text{H}_2\text{O}) & \xrightarrow{125^\circ\text{C}} & 2\text{CaSO}_4 \cdot \text{H}_2\text{O} + 3\text{H}_2\text{O} \\ \text{Gypsum} & & & & & & & & & & & & & \\ \end{array}$$

$$CaO + SO_3 \uparrow \leftarrow \frac{400^{\circ}C}{Anhydrous} 2CaSO_4 + H_2O$$

(b) 
$$Ag_2SO_4 \xrightarrow{923^{\circ}C} 2Ag + SO_2 + O_2$$

$$CuSO_4 \cdot 5H_2O \xrightarrow{100^{\circ}C} CuSO_4 \cdot H_2O \xrightarrow{230^{\circ}C} CuSO_4$$
Blue vitriol White vitriol

$$\begin{array}{c} \text{SO}_3 \uparrow + \text{CuO} \xleftarrow{800^{\circ}\text{C}}|\\ \text{ZnSO}_4 \cdot 7\text{H}_2\text{O} \xrightarrow{100^{\circ}\text{C}} \text{ZnSO}_4 \cdot \text{H}_2\text{O} \xrightarrow{280^{\circ}\text{C}} \text{ZnSO}_4\\ \text{White vitriol} \\ \text{ZnO} + \text{SO}_3 \uparrow \xleftarrow{800^{\circ}\text{C}}| \end{array}$$

Decomposition of green vitriol is similar to blue and white vitriol.

$$\begin{array}{ccc} \text{FeSO}_4 \cdot 7\text{H}_2\text{O} & \xrightarrow{140^{\circ}\text{C}} & \text{FeSO}_4 \cdot \text{H}_2\text{O} & \xrightarrow{300^{\circ}\text{C}} & \text{FeSO}_4 \\ \text{Green vitriol} & & & & & & & & \\ & & & & & & & & & \\ & & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & \\ & & & \\ & & \\ & & & \\ & & \\ & & & \\ & \\ & \\ & \\ & & \\ & \\ & & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ & \\ &$$

Note: Thermal decomposition of ferric sulphate also gives ferric oxide and SO<sub>3</sub> gas.

$$Fe_2(SO_4)_3 \xrightarrow{\Delta} Fe_2O_3 + 3SO_3 \uparrow$$

(c) Ammonium sulphate on heating melts with emission of ammonia gas. On further heating at about 300°C it finally decomposes to NH<sub>3</sub>, N<sub>2</sub> and SO<sub>2</sub> gases.

$$(NH_4)_2SO_4 \longrightarrow NH_4HSO_4 + NH_3\uparrow$$
  
 $3NH_4HSO_4 \longrightarrow NH_3 + N_2 + 3SO_2 + 6H_2O$ 

- Q. 5. Show the effect of heat on the following commercially important compounds:
  - (a) Borax, Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O
  - (b) Common alum, K<sub>2</sub>SO<sub>4</sub>Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>·24H<sub>2</sub>O
  - (c) Red lead, Pb3O4
  - (d) Orthoboric acid, H<sub>3</sub>BO<sub>3</sub>
  - (e) Orthophosphoric acid, H<sub>3</sub>PO<sub>4</sub>
  - (f) Potassium chlorate, KClO<sub>3</sub>
  - (g) Ammonium dichromate, (NH<sub>4</sub>)<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>
  - (h) Phosphorus acid, H<sub>3</sub>PO<sub>3</sub>
  - (i) Mixture of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> and NaNO<sub>3</sub>
  - (i) Ammonium nitrite, NH<sub>4</sub>NO<sub>2</sub>.
- Ans. (a) Borax on heating decomposes to give colourless glassy bead.  $Na_2B_4O_7\cdot 10H_2O\longrightarrow Na_2B_4O_7+10H_2O$

(b) First of all alum melts, undergoes dehydration and finally gives oxides of potassium and aluminium.

$$K_2SO_4\cdot Al_2(SO_4)_3\cdot 24H_2O \longrightarrow K_2SO_4\cdot Al_2(SO_4)_3 + 24H_2O$$

$$K_2O + Al_2O_3 + 4SO_3 \uparrow \leftarrow$$

(c) Red lead on heating at 470°C gives litharge.

$$2Pb_3O_4 \xrightarrow{470^{\circ}C} 6PbO + O_2 \uparrow$$

(d) Orthoboric acid on heating decomposes to give metaboric acid followed by tetraboric acid.

$$\begin{array}{c} \text{H}_{3}\text{BO}_{3} \xrightarrow{100^{\circ}\text{C}} & \text{HBO}_{2} & + & \text{H}_{2}\text{O} \\ \text{Metaboric acid} & + & \text{H}_{2}\text{O} \\ \end{array}$$

$$4\text{HBO}_{2} \xrightarrow{150^{\circ}\text{C}} & \text{H}_{2}\text{B}_{4}\text{O}_{7} & + & \text{H}_{2}\text{O} \\ & \text{Tetraboric acid} & + & \text{Tetraboric acid} \end{array}$$

(e) When orthophosphoric acid is heated at 250°C it changes to pyrophosphoric acid. On heating at 600°C, pyrophosphoric acid decomposes to give metaphosphoric acid.

2H<sub>3</sub>PO<sub>4</sub> 
$$\xrightarrow{250^{\circ}\text{C}}$$
  $\xrightarrow{\text{Pyrophosphoric acid}}$  + H<sub>2</sub>O

Pyrophosphoric acid + H<sub>2</sub>PO<sub>7</sub>  $\xrightarrow{600^{\circ}\text{C}}$  2HPO<sub>3</sub> + H<sub>2</sub>O

Metaphosphoric acid

(f) KClO<sub>3</sub> decomposes to a small extent at 370°C to give oxygen. On further heating the molten mass solidifies which contains both KCl and KClO<sub>4</sub> (potassium perchlorate).

Potassium perchlorate on thermal decomposition yields potassium chloride and oxygen.

$$2KClO_3 \xrightarrow{370^{\circ}C} 2KCl + 3O_2 \uparrow$$

$$4KClO_3 \longrightarrow 3KClO_4 + KCl$$

$$KClO_4 \xrightarrow{650^{\circ}C} KCl + 2O_2 \uparrow$$

(g) Decomposition of ammonium dichromate on heating yields  $N_2$  gas. It is a method of preparation of  $N_2$  gas.

$$(NH_4)_2Cr_2O_7 \xrightarrow{\Delta} Cr_2O_3 + 4H_2O + N_2$$

(h) Phosphorus acid on heating gives phosphine and orthophosphoric acid.

$$4H_3PO_3 \longrightarrow 3H_3PO_4 + PH_3$$

 Mixture of ammonium sulphate and sodium nitrate on heating gives nitrous oxide, i.e., laughing gas.

$$(NH_4)_2SO_4 + 2NaNO_3 \xrightarrow{\Delta} Na_2SO_4 + 2NH_4NO_3$$
  
 $NH_4NO_3 \longrightarrow N_2O + 2H_2O$ 

(j) Decomposition of ammonium nitrite on heating gives N2 gas.

$$NH_4NO_2 \xrightarrow{\Delta} N_2 + 2H_2O$$

- Q. 6. Show, what happens when the following chlorides are heated?
  - (a) NH<sub>4</sub>Cl
- (b) CuCl<sub>2</sub>·2H<sub>2</sub>O
- (c) MgCl<sub>2</sub>·6H<sub>2</sub>O
- (d) ZnCl<sub>2</sub>·2H<sub>2</sub>O

Ans. (a) Ammonium chloride decomposes to give  $NH_3(g)$  and HCl(g).

$$NH_4Cl(s) \xrightarrow{\Delta} NH_3(g) + HCl(g)$$

(b) Cupric chloride on heating gives cuprous chloride along with Cl<sub>2</sub> gas.

$$\begin{array}{ccc} CuCl_2 \cdot 2H_2O & \longrightarrow CuCl_2 + 2H_2O \\ & 2CuCl_2 & \longrightarrow Cu_2Cl_2 + Cl_2 \end{array}$$

(c) Hydrated zinc chloride when heated gives basic zinc chloride and zinc oxychloride.

$$ZnCl_2 \cdot 2H_2O \longrightarrow Zn(OH)Cl + HCl + H_2O$$
  
 $2ZnCl_2 \cdot H_2O \longrightarrow Zn_2OCl_2 + 2HCl + H_2O$ 

(d) Crystalline magnesium chloride on heating first of all loses its four water molecules. Dihydrate of magnesium chloride when further heated undergoes hydrolysis to give MgO along with HCl.

$$\begin{array}{c} \text{MgCl}_2\text{-}6\text{H}_2\text{O} \longrightarrow \text{MgCl}_2\text{-}2\text{H}_2\text{O} + 4\text{H}_2\text{O} \\ \text{MgCl}_2\text{-}2\text{H}_2\text{O} \xrightarrow{185^\circ\text{C}} \text{Mg(OH)Cl} + \text{HCl} + \text{H}_2\text{O} \\ \text{Mg(OH)Cl} \xrightarrow{600^\circ\text{C}} \text{MgO} + \text{HCl} \end{array}$$

- **Q. 7.** Show, what happens when the following compounds are heated?
  - (a) KMnO<sub>4</sub> (Potassium permanganate)
  - (b) K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> (Potassium dichromate)
  - (c) Plaster of Paris, [(CaSO<sub>4</sub>)<sub>2</sub>·H<sub>2</sub>O]
  - (d) Na<sub>2</sub>HPO<sub>4</sub> (Disodium hydrogen phosphate)
  - (e) [Na(NH<sub>4</sub>)HPO<sub>4</sub>·4H<sub>2</sub>O] (Microcosmic salt).
- Ans. (a) When KMnO<sub>4</sub> is heated, it decomposes evolving oxygen.

$$2KMnO_4 \xrightarrow{240^{\circ}C} K_2MnO_4 + MnO_2 + O_2$$

(b) Potassium dichromate, on heating strongly, decomposes liberating oxygen.

(c) On heating upto 200°C, it becomes anhydrous. The anhydrous salt decomposes into CaO and SO<sub>3</sub>.

 $4K_2Cr_2O_7 \longrightarrow 4K_2CrO_4 + 2Cr_2O_3 + 3O_2$ 

$$(CaSO4)2H2O \xrightarrow{200^{\circ}C} 2CaSO4 + H2O$$

$$CaSO4 \xrightarrow{400^{\circ}C} CaO + SO3$$

(d) Disodium hydrogen phosphate on heating first forms sodium pyrophosphate which on further heating forms sodium metaphosphate.

(e) When microcosmic salt is heated, it melts to form a clear transparent mass of sodium metaphosphate. Ammonia gas is evolved.

Na(NH<sub>4</sub>)HPO<sub>4</sub> 
$$\longrightarrow$$
 NaPO<sub>3</sub> + NH<sub>3</sub> + H<sub>2</sub>O
Sodium
metaphosphate

#### IMPORTANT CHEMICAL REACTIONS

- Q. 1. What happens when water reacts with the following compounds?
  - (a) Antimony chloride (SbCl<sub>3</sub>), bismuth chloride (BiCl<sub>3</sub>)
  - (b) Calcium cyanamide, CaCN<sub>2</sub>
  - (c) Calcium phosphide, Ca<sub>3</sub>P<sub>2</sub>
  - (d) Magnesium nitride, Mg<sub>3</sub>N<sub>2</sub>
  - (e) Red hot coke
  - (f) Red hot iron
  - (g) Borax.
- Ans. (a) Chlorides of both antimony and bismuth undergo hydrolysis to give white precipitates of their oxychlorides.

$$SbCl_3 + H_2O \longrightarrow SbOCl + 2HCl$$
  
 $BiCl_3 + H_2O \longrightarrow BiOCl + 2HCl$   
(White ppt.)

- (b) Calcium cyanamide on hydrolysis evolves  $NH_3(g)$ .  $CaCN_2 + 3H_2O \longrightarrow CaCO_3 + 2NH_3 \uparrow$
- (c) Calcium phosphide undergoes hydrolysis to evolve phosphine gas.

$$Ca_3P_2 + 6H_2O \longrightarrow 3Ca(OH)_2 + 2PH_3\uparrow$$

(d) Magnesium nitride reacts with water to form its hydroxide and ammonia gas.

$$Mg_3N_2 + 6H_2O \longrightarrow 3Mg(OH)_2 + 2NH_3\uparrow$$

(e) On passing steam over red hot coke, we get water gas.

$$C + H_2O(g) \longrightarrow \underbrace{CO^{\bullet} + H_2}_{\text{Water gas}}$$

(f) On passing steam over red hot iron, it gives ferrosoferric oxide and H<sub>2</sub> gas.

$$3\text{Fe} + 4\text{H}_2\text{O}(g) \longrightarrow \text{Fe}_3\text{O}_4 + 4\text{H}_2\uparrow$$

(g) Borax undergoes hydrolysis and the solution becomes alkaline due to NaOH.

$$Na_2B_4O_7 + 7H_2O \longrightarrow 4H_3BO_3 + 2NaOH$$

- Q. 2. Write down the products when H<sub>2</sub>O<sub>2</sub> reacts with following compounds:
  - (a) PbS (b) KI (c)  $H_2S$  (d)  $O_3$  (e)  $Ag_2O$
  - (f)  $FeSO_4$  (g)  $K_3[Fe(CN)_6]$  (h)  $KMnO_4$  (i)  $Cl_2$ .
- Ans. (a) Lead sulphide is oxidised to lead sulphate by H<sub>2</sub>O<sub>2</sub>.

$$\begin{array}{c}
4 \times [\text{H}_2\text{O}_2 \longrightarrow \text{H}_2\text{O} + [\text{O}]] \\
\text{PbS} + 4[\text{O}] \longrightarrow \text{PbSO}_4
\end{array}$$

$$\begin{array}{c}
\text{PbS} + 4\text{H}_2\text{O}_2 \longrightarrow \text{PbSO}_4 + 4\text{H}_2\text{O}}$$

- (b) On adding KI to H<sub>2</sub>O<sub>2</sub>, I<sub>2</sub> is liberated.
  - $2KI + H_2O_2 \longrightarrow 2KOH + I_2$

(c) Hydrogen peroxide oxidises H2S to sulphur.

$$\begin{array}{c} H_2O_2 \longrightarrow H_2O + [O] \\ H_2S + [O] \longrightarrow H_2O + S \\ \end{array}$$

$$H_2O_2 + H_2S \longrightarrow 2H_2O + S$$

(d) Mutual reduction of H<sub>2</sub>O<sub>2</sub> and O<sub>3</sub> takes place according to the following reaction.

$$H_2O_2 + O_3 \longrightarrow H_2O + 2O_2$$

(e) Hydrogen peroxide reduces Ag<sub>2</sub>O to silver metal.

$$H_2O_2 \longrightarrow H_2O + [O]$$

$$Ag_2O \longrightarrow 2Ag + [O]$$

$$[O] + [O] \longrightarrow O_2$$

$$H_2O_2 + Ag_2O \longrightarrow 2Ag + H_2O + O_2$$

(f) Ferrous sulphate is oxidised to ferric sulphate by H2O2.

$$\frac{H_2O_2 \longrightarrow H_2O + [O]}{2FeSO_4 + H_2SO_4 + [O] \longrightarrow Fe_2(SO_4)_3 + H_2O}$$
$$2FeSO_4 + H_2SO_4 + H_2O_2 \longrightarrow Fe_2(SO_4)_3 + 2H_2O$$

(g) In alkaline medium,  $K_3[Fe(CN)_6]$  is reduced to  $K_4[Fe(CN)_6]$  by  $H_2O_2$ .

$$2K_3Fe(CN)_6 + 2KOH + H_2O_2 \longrightarrow 2K_4[Fe(CN)_6] + O_2 + 2H_2O$$

(h) H<sub>2</sub>O<sub>2</sub> decolourises the pink colour of KMnO<sub>4</sub> solution.

$$5 \times [H_2O_2 \longrightarrow H_2O + [O]]$$

$$2KMnO4 + 3H2SO4 \longrightarrow K2SO4 + 2MnSO4 + 3H2O + 5[O]$$

$$5 [O] + 5[O] \longrightarrow 5O2$$

 $2KMnO_4 + 3H_2SO_4 + 5H_2O_2 \longrightarrow K_2SO_4 + 2MnSO_4 + 8H_2O_4$ 

 When Cl<sub>2</sub> is passed through H<sub>2</sub>O<sub>2</sub>, mutual reduction takes place.

$$H_2O_2 + Cl_2 \longrightarrow 2HCl + O_2$$

- Q. 3. What happens when CO<sub>2</sub> reacts with the following compounds?
  - (a) Na<sub>2</sub>CO<sub>3</sub>
- (b) Lime water, Ca(OH)<sub>2</sub>

(c) Mg

(d) Na.

**Ans.** (a) By passing CO<sub>2</sub> through aqueous Na<sub>2</sub>CO<sub>3</sub>, it is converted to bicarbonate.

$$Na_2CO_3 + H_2O + CO_2 \longrightarrow 2NaHCO_3$$

- (b)  $Ca(OH)_2 + CO_2 \longrightarrow CaCO_3 + H_2O$
- (c) Mg burns in the gas jar of CO<sub>2</sub>, forming its oxide and particles of carbon.

$$2Mg + CO_2 \longrightarrow 2MgO + C$$

(d) On heating Na in a gas jar of CO<sub>2</sub>, formation of sodium carbonate takes place.

$$4Na + 3CO_2 \longrightarrow 2Na_2CO_3 + C$$

- Q. 4. What happens when N<sub>2</sub> reacts with the following compounds?
  - (a) Mg (b) CaC<sub>2</sub> (c) Coke and alumina.
- Ans. (a) On passing  $N_2$  over hot Mg we get nitride.

$$3Mg + N_2 \xrightarrow{\Delta} Mg_3N_2$$

(b) By passing N<sub>2</sub> over red hot CaC<sub>2</sub> we get calcium cyanamide which is used as nitrolim fertilizer.

$$CaC_2 + N_2 \longrightarrow CaCN_2 + C$$

(c) When N<sub>2</sub> is passed through red hot coke and aluminium we get nitride of aluminium.

$$Al_2O_3 + N_2 + C \longrightarrow 2AlN + 3CO$$

- Q. 5. What happens when NO gas is passed through?
  - (a) FeSO<sub>4</sub>

- (b) Na<sub>2</sub>CO<sub>3</sub>.
- Ans. (a) FeSO<sub>4</sub> forms reddish-brown compound with NO called nitrosoferrous sulphate.

$$FeSO_4 + NO \longrightarrow FeSO_4 \cdot NO$$

(b) On passing a mixture of NO and NO<sub>2</sub> through aqueous washing soda we get sodium nitrite.

$$Na_2CO_3 + NO + NO_2 \longrightarrow 2NaNO_2 + CO_2$$

**Q. 6.** Show how carbon monoxide (CO) reacts with Cl<sub>2</sub> and cupric oxide?

Ans. CO gas combines with chlorine to give phosgene.

$$CO + Cl_2 \longrightarrow COCl_2$$

Carbon monoxide reduces cupric oxide to copper.

$$CuO + CO \longrightarrow Cu + CO_2$$

- Q. 7. What happens when caustic soda or caustic potash reacts with?
  - (a) Zn (b) Pb (c) Sn (d) Al (e) Yellow P (f) Sulphur
  - (g) Chlorine, bromine or iodine (h) ZnSO<sub>4</sub>, ZnCl<sub>2</sub> (i) Al<sub>2</sub>O<sub>3</sub>
  - (j) CuSO<sub>4</sub> (k) AgNO<sub>3</sub> (l) SnCl<sub>2</sub> (m) NaNO<sub>3</sub> and Al (n) HgCl<sub>2</sub>
  - (o) Ammonium salts.
- Ans. (a) H<sub>2</sub> gas is evolved when Zn reacts with caustic soda.

 $2NaOH + Zn \longrightarrow Na_2ZnO_2 + H_2\uparrow$ 

(b) Pb reacts with NaOH, just like Zn.

$$2NaOH + Pb \longrightarrow Na_2PbO_2 + H_2$$

(c) Tin dissolves in NaOH to form sodium stannate along with H<sub>2</sub> gas.

$$Sn + 2NaOH + H_2O \longrightarrow Na_2SnO_3 + 2H_2\uparrow$$

(d) On boiling aluminium powder with NaOH we get sodium metaaluminate and aluminate.

- (e) Yellow phosphorus reacts with alkali to give phosphine.  $P_4 + 3NaOH + 3H_2O \longrightarrow PH_3 + 3NaH_2PO_2$
- (f) Sulphur dissolves in alkali to give sodium pentasulphide and sodium thiosulphate.

$$12S + 6NaOH \longrightarrow Na_2S_2O_3 + 2Na_2S_5 + 3H_2O$$

(g) Chlorine, bromine or iodine reacts with alkali in similar

$$\begin{array}{c} Cl_2 + 2NaOH(dil.) \longrightarrow \ NaCl + NaClO + H_2O \\ 3Cl_2 + 6NaOH(conc.) \longrightarrow 5NaCl + NaClO_3 + 3H_2O \\ Similarly, \end{array}$$

$$Br_2 + 2NaOH(dil.) \longrightarrow NaBr + NaBrO + H_2O$$
  
 $3Br_2 + 6NaOH(conc.) \longrightarrow 5NaBr + NaBrO_3 + 3H_2O$   
 $I_2 + 2NaOH(dil.) \longrightarrow NaI + NaIO + H_2O$   
 $3I_2 + 6NaOH(conc.) \longrightarrow 5NaI + NaIO_3 + 3H_2O$ 

(h) When salts of Zn are treated with NaOH, white precipitate of hydroxide is formed which dissolves in excess of NaOH.

(i) Al<sub>2</sub>O<sub>3</sub> dissolves in NaOH forming sodium metaaluminate.

$$Al_2O_3 + 2NaOH \longrightarrow 2NaAlO_2 + H_2O$$

(j) CuSO<sub>4</sub> forms precipitate of Cu(OH)<sub>2</sub>, when added to NaOH.

$$CuSO_4 + 2NaOH \longrightarrow Cu(OH)_2 + 2Na_2SO_4$$

- (k) AgNO<sub>3</sub> on treatment with NaOH, gives precipitate of Ag<sub>2</sub>O.  $2AgNO_3 + 2NaOH \longrightarrow 2NaNO_3 + Ag_2O + H_2O$ (ppt.)
- (1) SnCl<sub>2</sub> dissolves in NaOH to give white precipitate of Sn(OH)<sub>2</sub>. Precipitate dissolves in excess of NaOH.

$$SnCl_2 + 2NaOH \longrightarrow 2NaCl + Sn(OH)_2$$
(White ppt.)

$$Sn(OH)_2 + 2NaOH \longrightarrow Na_2SnO_2 + 2H_2O$$

- (m)  $3NaNO_3 + 8AI + 5NaOH + 2H_2O \longrightarrow 8NaAlO_2 + 3NH_3$
- (n) On heating with NaOH solution, mercuric chloride forms a yellow precipitate of mercuric oxide.

$$HgCl_2 + 2NaOH \longrightarrow HgO + 2NaCl + H_2O$$

(o) Ammonium salts on heating with NaOH solution, liberate NH<sub>3</sub> gas.

$$NH_4Cl + NaOH \longrightarrow NH_3 + NaCl + H_2O$$
Ammonium
chloride

$$(NH_4)_2SO_4 + 2NaOH \longrightarrow 2NH_3 + Na_2SO_4 + 2H_2O$$

- **O. 8.** What happens when?
  - (a) SO<sub>2</sub> gas is passed through a suspension of iodine in water.
  - (b) Metallic zinc is added to alkaline sodium nitrite solution.
- (a) SO<sub>2</sub> reduces I<sub>2</sub> to HI and itself undergoes oxidation to H<sub>2</sub>SO<sub>4</sub>.  $SO_2 + I_2 + 2H_2O \longrightarrow H_2SO_4 + 2HI$

(b) 
$$Zn + 2NaOH \longrightarrow Na_2ZnO_2 + 2[H]$$
  
 $NaNO_2 + 6[H] \xrightarrow{Zn/NaOH} NaOH + NH_3 + H_2O$ 

Q. 9. What happens when ozone reacts with?

- (a) Hg (b) Ag (c)  $K_4[Fe(CN)_6]$ (d)  $K_2MnO_4$
- (e) KI (f) PbS (g) S (h) P.

(a) Mercury is oxidised to mercurous oxide, which sticks to the Ans. walls of the glass vessel.

$$\begin{array}{c} O_3 \longrightarrow O_2 + [O] \\ 2Hg + [O] \longrightarrow Hg_2O \\ \hline 2Hg + O_3 \longrightarrow O_2 + Hg_2O \end{array}$$

(b) Silver is oxidised to its oxide.

$$\begin{array}{c} O_3 \longrightarrow O_2 + [O] \\ 2Ag + [O] \longrightarrow Ag_2O \\ 2Ag + O_3 \longrightarrow Ag_2O + O_2 \end{array}$$

(c) Potassium ferrocyanide is oxidised to potassium ferricyanide.

$$\begin{array}{c} O_3 \longrightarrow O_2 + [O] \\ 2K_4[Fe(CN)_6] + H_2O + [O] \longrightarrow 2K_3[Fe(CN)_6] + 2KOH \end{array}$$

$$2K_3[re(CN)_6] + R_2O + [O] \longrightarrow 2K_3[re(CN)_6] + 2KON$$

$$2K_4[Fe(CN)_6] + O_3 + H_2O \longrightarrow 2K_3[Fe(CN)_6] + 2KOH + O_2$$
  
(d) Potassium manganate is converted to potassium permanganate

by passing O<sub>3</sub> gas through its aqueous solution.

2KI + 
$$H_2O$$
 +  $O_3$   $\longrightarrow$  2KOH +  $I_2$  +  $O_2$ 

(f) Lead sulphide is oxidised to lead sulphate.

$$4 \times [O_3 \longrightarrow O_2 + [O]]$$

$$PbS + 4[O] \longrightarrow PbSO_4$$

$$PbS + 4O_3 \longrightarrow PbSO_4 + 4O_2$$

(g) Sulphur is oxidised to sulphuric acid in aqueous medium.

$$3 \times [O_3 \longrightarrow O_2 + [O]]$$

$$S + 3[O] \longrightarrow SO_3$$

$$H_2O + SO_3 \longrightarrow H_2SO_4$$

$$3O_3 + S + H_2O \longrightarrow H_2SO_4 + 3O_2$$

(h) Ozone oxidises phosphorus to phosphorus pentoxide which dissolves in water to give orthophosphoric acid.

$$5 \times [O_3 \longrightarrow O_2 + [O]] 
2P + 5[O] \longrightarrow P_2O_5 
P_2O_5 + 3H_2O \longrightarrow 2H_3PO_4$$

$$2P + 5O_3 + 3H_2O \longrightarrow 2H_3PO_4 + 5O_2$$

- **Q.10.** What happens when?
  - (a) Mixture of red phosphorus and iodine is heated with
  - (b) Calcium phosphate is heated with sand and coke.
  - (c) Phosphorus is heated with sulphur.
  - (d) Aqua-regia is added to gold.

(a) On boiling the mixture of red P and I2 with water, we get Ans. hydrogen iodide and phosphorus acid.

$$\begin{array}{c}
2P + 3I_2 \longrightarrow 2PI_3 \\
[PI_3 + 3H_2O \longrightarrow H_3PO_3 + 3HI] \times 2\\
\hline
2P + 3I_2 + 6H_2O \longrightarrow 2H_3PO_3 + 6HI
\end{array}$$

(b) It is a method of preparation of white phosphorus.

$$Ca_3(PO_4)_2 + 3SiO_2 \longrightarrow 3CaSiO_3 + P_2O_5$$
  
 $P_2O_5 + 5C \longrightarrow 2P + 5CO\uparrow$ 

(c) When phosphorus reacts with sulphur we get tri- and pentasulphides, which are used in the tip of matchstick.

$$4P + 6S \longrightarrow 2P_2S_3$$

$$4P + 10S \longrightarrow 2P_2S_5$$

Ans.

(d) Gold dissolves in aqua-regia to form chloroauric acid.

$$\begin{array}{l} 3\times [HNO_3+3HCl \longrightarrow NOCl+2H_2O+2[Cl]] \\ 2\times [Au+3[Cl] \longrightarrow AuCl_3] \\ 2\times [AuCl_3+HCl \longrightarrow H[AuCl_4]] \end{array}$$

 $3HNO_3 + 2Au + 11HCl \longrightarrow 3NOCl + 6H_2O + 2H[AuCl_4]$ 

Q.11. What happens when ammonia reacts with?

- (a) Silver nitrate
- (b) Silver chloride
- (c) Copper sulphate
- (d) Iodine
- (e) Zinc chloride
- (f) Nessler's reagent
- (g) Mercurous chloride
- (h) Sodium

(i) CuO

- (j) Chlorine
- (k) Bromine.
- (a) Silver nitrate dissolves in ammonia solution forming complex.
   AgNO<sub>3</sub> + 2NH<sub>4</sub>OH → [Ag(NH<sub>3</sub>)<sub>2</sub>]NO<sub>3</sub> + 2H<sub>2</sub>O

Diamminesilver nitrate
(b) Silver chloride also dissolves in ammonia forming complex

compound. 
$$\begin{array}{c} AgCl + 2NH_4OH \longrightarrow [Ag(NH_3)_2]Cl \\ Diamminesilver(I) \\ chloride \end{array} + 2H_2O$$

(c) When ammonia solution is added to copper sulphate, we get dark blue coloured complex compound.

$$CuSO_4 + 4NH_4OH \longrightarrow [Cu(NH_3)_4]SO_4 + 4H_2O$$
Tetraamminecopper(II)
sulphate

(d) Iodine forms an explosive compound with ammonia.
 2NH<sub>3</sub> + 3I<sub>2</sub> → NH<sub>3</sub>NI<sub>3</sub> + 3HI

(e) When ammonia solution is added to zinc chloride we get white precipitate which dissolves in excess of ammonia solution.

$$ZnCl_2 + 2NH_4OH \longrightarrow Zn(OH)_2 + 2NH_4Cl$$

$$Zn(OH)_2 + 2NH_4OH + 2NH_4Cl \longrightarrow [Zn(NH_3)_4]Cl_2 + 4H_2O$$

$$ZnCl_2 + 4NH_4OH \longrightarrow [Zn(NH_3)_4]Cl_2 + 4H_2O$$
Tetraamminezinc

(f) Nessler's reagent is used to test ammonia. It gives brown precipitate of iodide of Millon's base when ammonia gas is passed through it.

$$2K_2HgI_4 + NH_3 + 3KOH \longrightarrow Hg O + 7KI + 2H_2O$$

Iodide of Millon's base

(g) White precipitate of mercurous chloride dissolves in ammonia solution and gives black residue of basic mercuric chloride and mercury.

$$Hg_2Cl_2 + 2NH_4OH \longrightarrow \underbrace{HgNH_2Cl + Hg}_{Black ppt.} + NH_4Cl + 2H_2O$$

(h) Sodium dissolves in liquid ammonia forming blue coloured solution due to presence of solvated electrons.

Na + 
$$(x + y)NH_3 \longrightarrow Na(NH_3)_x^+ + (NH_3)_y^+$$
  
(Solvated electrons)

When dry  $NH_3(g)$  comes in contact with sodium, it gives nascent hydrogen which is used to reduce various organic compounds.

$$Na + NH_3(g) \longrightarrow NaNH_2 + [H]$$

(i) Red hot cupric oxide reduces NH3 gas to nitrogen.

$$3CuO + 2NH_3 \longrightarrow 3Cu + N_2 + 3H_2O$$

(j) Chlorine oxidises ammonia (excess) to nitrogen.

$$8NH_3 + 3Cl_2 \longrightarrow N_2 + 6NH_4Cl$$

When chlorine is in excess, ammonia reacts with it to form an explosive.

$$NH_3 + 3Cl_2 \longrightarrow NCl_3 + 3HCl$$

(k) Reaction of Br<sub>2</sub> with ammonia is similar to the reaction of Cl<sub>2</sub> with ammonia.

$$\begin{array}{l} 8NH_3 + 3Br_2 {\longrightarrow} \ N_2 + 6NH_4Br \\ NH_3 + 3Br_2 {\longrightarrow} \ NBr_3 + 3HBr \end{array}$$

Q.12. What happens when?

- (a) Sodium thiosulphate is added to silver nitrate.
- (b) Nitrogen is passed through red hot alumina and coke.
- (c) Iodine is added to the mixture of Na<sub>2</sub>SO<sub>3</sub> and Na<sub>2</sub>S.
- (d) Ammonium thiocyanate is added to ferric chloride.

Ans. (a) Formation of complex compound takes place.

$$2Na_2S_2O_3 + AgNO_3 \longrightarrow Na_3[Ag(S_2O_3)_2] + NaNO_3$$

b)  $Al_2O_3 + 3C + N_2 \longrightarrow 2AlN + 3CO\uparrow$ 

(c) Iodine reacts with the mixture of Na<sub>2</sub>SO<sub>3</sub> and Na<sub>2</sub>S to form sodium thiosulphate.

$$Na_2S + Na_2SO_3 + I_2 \longrightarrow Na_2S_2O_3 + 2NaI$$

(d) Ammonium thiocyanate is the reagent to test ferric ion; formation of blood red coloured ferric thiocyanate takes place.

$$FeCl_3 + 3NH_4SCN \longrightarrow Fe(SCN)_3 + 3NH_4Cl$$
Blood red

- **Q.13.** Write down the reaction product of chlorine with the following compounds. Give the involved reactions also.
  - (a) Mixture of alumina and coke
  - (b) Phosphine
  - (c) Iodine in aqueous medium
  - (d) Carbon monoxide
  - (e) Lime
  - (f) H<sub>2</sub>S gas
  - (g) KI
  - (h) Hypo (sodium thiosulphate).

Ans. (a)  $Al_2O_3 + 3C + 3Cl_2 \longrightarrow 2AlCl_3 + 3CO\uparrow$ 

(b) Phosphine burns in atmosphere of chlorine, forming PCl<sub>5</sub> and HCl.

$$PH_3 + 4Cl_2 \longrightarrow PCl_5 + 3HCl$$

(c) Chlorine oxidises iodine to iodic acid in aqueous medium.

$$\begin{split} & [\text{Cl}_2 + \text{H}_2\text{O} \longrightarrow 2\text{HCl} + [\text{O}]] \times 5 \\ & \text{I}_2 + 5[\text{O}] \longrightarrow \text{I}_2\text{O}_5 \\ & \text{I}_2\text{O}_5 + \text{H}_2\text{O} \longrightarrow 2\text{HIO}_3 \\ \hline & \text{I}_2 + 5\text{Cl}_2 + 6\text{H}_2\text{O} \longrightarrow 2\text{HIO}_3 + 10\text{HCl} \end{split}$$

(d) Chlorine combines with carbon monoxide to form a poisonous gas phosgene.

$$CO(g) + Cl_2(g) \longrightarrow COCl_2$$
Phosgene

(e) **Lime:** (i) On passing Cl<sub>2</sub> gas through hot and concentrated lime water we get calcium chloride and calcium chlorate.

$$6\text{Ca}(\text{OH})_2 + 6\text{Cl}_2 \longrightarrow 5\text{Ca}\text{Cl}_2 + \text{Ca}(\text{ClO}_3)_2 + 6\text{H}_2\text{O}$$
Calcium chlorate

(ii) Cl<sub>2</sub> gas gives calcium hypochloride on passing through cold and dilute lime water.

$$2Ca(OH)_2 + 2Cl_2 \longrightarrow CaCl_2 + Ca(OCl)_2 + 2H_2O$$

(iii) On passing Cl<sub>2</sub> through dry lime we get bleaching powder.

$$Ca(OH)_2 + Cl_2 \longrightarrow CaOCl_2 + H_2O$$
(Bleaching powder)

(f) On passing mixture of Cl<sub>2</sub> and H<sub>2</sub>S through a hot tube, oxidation of H<sub>2</sub>S to sulphur takes place.

$$H_2S + Cl_2 \longrightarrow 2HCl + S$$

(g) Chlorine is more reactive than iodine, hence, it displaces iodine from iodide salts.

$$Cl_2 + 2KI \longrightarrow 2KCl + I_2$$

(h) Chlorine water oxidises sodium thiosulphate to sodium sulphate.

$$Cl_2 + H_2O \longrightarrow 2HCl + [O]$$

$$Na_2S_2O_3 + [O] \longrightarrow Na_2SO_4 + S$$

$$Na_2S_2O_3 + Cl_2 + H_2O \longrightarrow Na_2SO_4 + 2HCl + S$$

#### Q.14. What happens when?

- (a) Iodine is added to sodium thiosulphate.
- (b) Iodine is dissolved in aqueous solution of KI.
- (c) Iodine is added to stannous chloride in acid medium.
- (d) Iodine is allowed to react with aq. KOH.

(a) Iodine changes sodium thiosulphate to sodium tetrathionate.  $2Na_2S_2O_3 + I_2 \longrightarrow 2NaI + Na_2S_4O_6$ 

(b) Iodine dissolves in aqueous KI forming potassium triiodide.  $KI + I_2 \rightarrow KI_3$ 

(c) Iodine oxidises SnCl2 to SnCl4.

$$SnCl_2 + 2HCl + I_2 \longrightarrow SnCl_4 + 2HI$$

(d) Iodine converts cold and dilute KOH to potassium hypoiodite.

$$2KOH + I_2 \longrightarrow KI + KIO + H_2O$$

With hot KOH, Iodine forms KI and potassium iodate.

$$6\text{KOH} + 3\text{I}_2 \longrightarrow 5\text{KI} + \text{KIO}_3 + 3\text{H}_2\text{O}$$

#### Q.15. What happens when:

- (a) Chromium hydroxide is treated with hydrogen peroxide in the presence of sodium hydroxide.
- (b) Hydrolith is treated with water.
- (c) Concentrated solution of NH<sub>4</sub>HSO<sub>4</sub> in H<sub>2</sub>SO<sub>4</sub> is electrolysed using current of high density.
- (d) Hydrazine reacts with hydrogen peroxide.
- (e) Tin tetrachloride reacts with lithium aluminium hydride.
- (f) Sodium hydride reacts with diborane.
- (g) Anhydrous potassium nitrate is heated with excess of metallic potassium.
- (h) Beryllium chloride reacts with LiAlH<sub>4</sub>.
- (i) A mixture of borax and cobalt oxide is heated in a flame.
- (j) Tin is treated with concentrated nitric acid.
- (k) Red lead is treated with nitric acid.
- (l) Carbon dioxide is passed through a concentrated aqueous solution of sodium chloride saturated with
- (m) Lead is reacted with acetic acid in presence of oxygen.
- (n) Stannous chloride is reacted with mercuric chloride
- (o) Potassium ferrocyanide is heated with concentrated
- (p) Silica is heated with CaF<sub>2</sub> and concentrated H<sub>2</sub>SO<sub>4</sub>.
- (q) Phosphine is treated with an acidified copper sulphate
- (r) Iodine reacts with concentrated nitric acid.
- (s) Orthophosphoric acid is heated with conc. nitric acid and ammonium molybdate.
- (t) Disodium hydrogen phosphate is added to ammonical solution of magnesium sulphate.
- (u) Phosphine is passed through silver nitrate solution.
- (v) Ammonia reacts with sodium hypochlorite.

- (w) Copper sulphate is treated with hypophosphorus acid.
- (x) Mercuric chloride is treated with hypophosphorus acid.
- (y) Phosphorus pentachloride reacts with sulphuric acid.
- (z) Phosphoric acid reacts with Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>F.

(a) Chromium hydroxide is converted into soluble sodium Ans. chromate.

$$2Cr(OH)_3 + 4NaOH + 3H_2O_2 \longrightarrow 2Na_2CrO_4 + 8H_2O$$

(b) Hydrolysis of CaH2 occurs with evolution of hydrogen.

$$CaH_2 + 2H_2O \longrightarrow Ca(OH)_2 + 2H_2\uparrow$$

(c) Ammonium peroxydisulphate is formed.

$$NH_4HSO_4 \iff H^+ + NH_4SO_4^-$$

 $2\mathrm{NH_4SO_4^-} \longrightarrow (\mathrm{NH_4})_2\mathrm{S}_2\mathrm{O}_8 \ + \ 2e$ At anode:  $2H^+ + 2e \longrightarrow H_2$ 

At cathode:

(d) Hydrazine is oxidised to N2 and H2O.

$$N_2H_4 + 2H_2O_2 \longrightarrow N_2 + 4H_2O$$

(e) Tin hydride is formed.

$$SnCl_4 + LiAlH_4 \longrightarrow SnH_4 + LiCl + AlCl_3$$

(f) Sodium hydride reacts with diborane to form sodium borohydride.

$$2NaH + B_2H_6 \longrightarrow 2NaBH_4$$

(g) Nitrogen is released with the formation of K2O.

$$2KNO_3 + 10K \longrightarrow N_2 + 6K_2O$$

(h) Beryllium hydride is formed.

$$2\text{BeCl}_2 + \text{LiAlH}_4 \longrightarrow 2\text{BeH}_2 + \text{LiCl} + \text{AlCl}_3$$

 $Na_2B_4O_7 \cdot 10H_2O \xrightarrow{-10H_2O} Na_2B_4O_7 \longrightarrow$ 

$$2NaBO_2 + B_2O_3$$

Boron anhydride combines with cobalt oxide to form cobalt metaborate.

Sn dissolves in conc. HNO<sub>3</sub> forming metastannic acid.

Sn + 4HNO<sub>3</sub> 
$$\longrightarrow$$
 H<sub>2</sub>SnO<sub>3</sub> + 4NO<sub>2</sub> + H<sub>2</sub>O  
Metastannic  
acid

(k) Red lead, when treated with conc. HNO3, forms lead nitrate and brownish black insoluble PbO2. This indicates that red lead is a mixed oxide containing PbO and PbO<sub>2</sub>.

$$Pb_3O_4 + 4HNO_3 \longrightarrow 2Pb(NO_3)_2 + PbO_2 + 2H_2O$$

(1) CO<sub>2</sub> reacts with ammonium hydroxide to form ammonium bicarbonate, which then reacts with NaCl to form sodium bicarbonate. This is Solvay's process for manufacture of washing soda.

$$NH_4OH + CO_2 \longrightarrow NH_4HCO_3$$
  
 $NaCl + NH_4HCO_3 \longrightarrow NaHCO_3 + NH_4Cl$ 

(m) Lead dissolves in acetic acid in presence of oxygen in the form of lead acetate.

Pb + 2CH<sub>3</sub>COOH + 
$$\frac{1}{2}$$
O<sub>2</sub>  $\longrightarrow$  Pb(CH<sub>3</sub>COO)<sub>2</sub> + H<sub>2</sub>O

(n) Redox reaction occurs SnCl<sub>2</sub> first reduces HgCl<sub>2</sub> to Hg<sub>2</sub>Cl<sub>2</sub> and then into Hg.

$$2HgCl_2 + SnCl_2 \longrightarrow Hg_2Cl_2 + SnCl_4;$$
  
 $Hg_2Cl_2 + SnCl_2 \longrightarrow 2Hg + SnCl_4$ 

(o) Carbon monoxide is evolved when potassium ferrocyanide is heated with conc. H2SO4.

$$K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O \longrightarrow 2K_2SO_4 + FeSO_4 + 3(NH_4)_2SO_4 + 6CO$$

(p) H<sub>2</sub>SO<sub>4</sub> evolves H<sub>2</sub>F<sub>2</sub> from CaF<sub>2</sub> which reacts with silica to form silicon tetrafluoride.

$$CaF_2 + H_2SO_4 \longrightarrow CaSO_4 + H_2F_2;$$
  
 $SiO_2 + 2H_2F_2 \longrightarrow SiF_4 + 2H_2O$ 

(q) Copper phosphide is formed.

$$3CuSO_4 + 2PH_3 \longrightarrow Cu_3P_2 + 3H_2SO_4$$

(r) Iodine is oxidised to iodine pentoxide which combines with water to form iodic acid.

 $I_2 + 10HNO_3 \longrightarrow 2HIO_3 + 10NO_2 + 4H_2O$ 

(s) This is a test of phosphate ion. A yellow canary precipitate of ammonium phosphomolybdate is formed.

 $H_3PO_4 + 21HNO_3 + 12(NH_4)_3MoO_4 \longrightarrow$ 

 $(NH_4)_3PO_4\cdot 12MoO_3 + 21NH_4\cdot NO_3 + 12H_2O_3$ 

(t) This is a test of magnesium ion. A white precipitate magnesium ammonium phosphate is formed.

$$MgSO_4 + Na_2HPO_4 + NH_4OH \longrightarrow MgNH_4PO_4$$

+ Na<sub>2</sub>SO<sub>4</sub> + H<sub>2</sub>O

(u) Silver phosphide is formed.

$$3AgNO_3 + PH_3 \longrightarrow Ag_3P + 3HNO_3$$

(v) Ammonia is oxidised to nitrogen.

$$2NH_3 + 3NaClO \longrightarrow N_2 + 3NaCl + 3H_2O$$

or when a strong aqueous solution of ammonia is boiled with sodium hypochlorite in presence of glue, hydrazine is formed.

$$2NH_3 + NaClO \longrightarrow NH_2 \longrightarrow NH_2 + NaCl + H_2O$$

(w) Copper sulphate is reduced to cuprous hydride.

$$4\text{CuSO}_4 + 3\text{H}_3\text{PO}_2 + 6\text{H}_2\text{O} \longrightarrow 2\text{Cu}_2\text{H}_2 + 3\text{H}_3\text{PO}_4$$

+ 4H<sub>2</sub>SO

Ans.

 (x) Mercuric chloride is réduced to mercurous chloride and finally to metallic mercury.

$$2HgCl_2 + H_3PO_2 + 2H_2O \longrightarrow 2Hg + H_3PO_4 + 4HCl$$

(y) Hydroxyl groups of H<sub>2</sub>SO<sub>4</sub> are replaced by chlorine atoms to form sulphuryl chloride.

$$SO_2(OH)_2 + PCl_5 \longrightarrow SO_2Cl_2 + POCl_3 + 2HCl$$
  
Sulphuric acid Sulphuryl chloride

(z) Hydrofluoric acid is evolved.

 $Ca_5(PO_4)_3F + 7H_3PO_4 + 5H_2O \longrightarrow 5Ca(H_2PO_4)_2 \cdot H_2O + HF$  **Q.16.** What happens when:

- (i) Sulphur dioxide is bubbled through aqueous solution of copper sulphate in presence of potassium thiocyanate.
- (ii) Hydrogen sulphide is bubbled through an aqueous solution of sulphur dioxide.
- (iii) Hydrogen sulphide is passed through acidified ferric chloride solution.
- (iv) Hydrogen sulphide is passed through sodium bisulphite solution.
- (v) Potassium chlorate is heated with conc. H<sub>2</sub>SO<sub>4</sub>.
- (vi) Arsine is passed through silver nitrate solution.
- (vii) Sodium chloride and manganese dioxide mixture is heated with conc. H<sub>2</sub>SO<sub>4</sub>.
- (viii) Silver bromide is treated with hypo solution.
- (ix) Cupric chloride is heated with copper turnings and conc. HCl.
- (x) Silver chloride is treated with aqueous NaCN and the product is treated with zinc in alkaline solution.
- (xi) Potassium ferrocyanide solution is added to a solution of ferric chloride.
- (xii) Metal chloride is heated with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and conc. H<sub>2</sub>SO<sub>4</sub>.
- (xiii) Sodium iodate is reacted with sodium bisulphite.
- (xiv) Copper sulphate is treated with potassium iodide followed by addition of hypo solution.
- (xv) A mixture of silver chloride and sodium carbonate is heated.

- (xvi) Potassium iodide is added to bleaching powder containing dilute acetic acid.
- (xvii) Xenon hexafluoride is hydrolysed.
- (xviii) Potassium nitrite reacts with cobalt chloride in presence of acetic acid.
- (xix) Potassium iodide is added in excess to the solution of ferric sulphate.
- (xx) Copper is left in moist air.
- (xxi) Water reacts with Al<sub>4</sub>C<sub>3</sub>.
- (xxii) Water reacts with XeF<sub>4</sub>.
- (xxiii) Water reacts with NCl<sub>3</sub>.

(i) A white precipitate of cuprous thiocyanate is formed.  $2\text{CuSO}_4 + \text{SO}_2 + 2\text{KCNS} + 2\text{H}_2\text{O} \longrightarrow 2\text{CuCNS} + \text{K}_2\text{SO}_4 + 2\text{H}_2\text{SO}_4$ 

(ii) Sulphur is precipitated.

$$2H_2S + SO_2 \longrightarrow 3S + 2H_2O$$

(iii) Reduction of FeCl<sub>3</sub> occurs with precipitation of sulphur.  $H_2S + 2FeCl_3 \longrightarrow 2FeCl_2 + 2HCl + S$ 

(iv) Sulphur is precipitated.

$$2NaHSO_3 \longrightarrow Na_2SO_3 + H_2O + SO_2$$
  
 $SO_2 + 2H_2S \longrightarrow 3S + 2H_2O$ 

(v) Chlorine dioxide is evolved with explosion.

$$3KClO_3 + 3H_2SO_4 \longrightarrow 3KHSO_4 + HClO_4$$

+ 2ClO<sub>2</sub> + H<sub>2</sub>O

(vi) Black precipitate of silver is obtained. AsH<sub>3</sub> acts as a reducing agent.

$$AsH_3 + 6AgNO_3 + 3H_2O \longrightarrow 6Ag + 6HNO_3 + H_3AsO_3$$

(vii) Chlorine gas is evolved.

$$\begin{aligned} [\text{NaCl} + \text{H}_2\text{SO}_4 &\longrightarrow \text{NaHSO}_4 + \text{HCl}] \times 2 \\ \text{MnO}_2 + \text{H}_2\text{SO}_4 &\longrightarrow \text{MnSO}_4 + \text{H}_2\text{O} + [\text{O}] \\ 2\text{HCl} + [\text{O}] &\longrightarrow \text{Cl}_2 + \text{H}_2\text{O} \end{aligned}$$

$$2NaCl + MnO_2 + 3H_2SO_4 \longrightarrow 2NaHSO_4 + MnSO_4$$

+ 2H<sub>2</sub>O + Cl<sub>2</sub>

(viii) Silver bromide dissolves in hypo solution forming sodium argentothiosulphate.

$$AgBr + 2Na_2S_2O_3 \longrightarrow Na_3[Ag(S_2O_3)_2] + NaBr$$

- (ix) White precipitate of  $Cu_2Cl_2$  (cuprous chloride) is formed.  $CuCl_2 + Cu \longrightarrow Cu_2Cl_2$
- (x) AgCl dissolves in NaCN forming sodium argenocyanide complex. Zinc displaces silver from this complex being more electropositive in nature.

$$AgCl + 2NaCN \longrightarrow Na[Ag(CN)_2] + NaCl 2Na[Ag(CN)_2] + Zn \longrightarrow Na_2Zn(CN)_4 + 2Ag$$

(xi) Dark blue coloured precipitate (prussian blue) of ferri-ferrocyanide is obtained.

$$4\text{FeCl}_3 + 3\text{K}_4\text{Fe}(\text{CN})_6 \longrightarrow \text{Fe}_4[\text{Fe}(\text{CN})_6]_3 + 12\text{KCl}$$
  
Ferri-ferrocyanide

(xii) Reddish yellow vapours of chromyl chloride are evolved.

$$K_2Cr_2O_7 + 2H_2SO_4 \longrightarrow 2KHSO_4 + 2CrO_3 + H_2O$$

$$[KCl + H_2SO_4 \longrightarrow KHSO_4 + HCl] \times 4$$

$$2CrO_3 + 4HCl \longrightarrow 2CrO_2Cl_2 + 2H_2O$$

$$\begin{array}{l} \text{K}_2\text{Cr}_2\text{O}_7 + 6\text{H}_2\text{SO}_4 + 4\text{KCl} \longrightarrow 2\text{CrO}_2\text{Cl}_2 \\ + 6\text{KHSO}_4 + 3\text{H}_2\text{O} \end{array}$$

(xiii) Iodine is formed.

$$2NaIO_3 + 5NaHSO_3 \longrightarrow 3NaHSO_4 + 2Na_2SO_4$$

 $+ H_2O + I_2$ 

(xiv) Iodine is first evolved which reacts with hypo forming sodium tetrathionate and sodium iodide. White precipitate of cuprous iodide is formed.

$$\begin{array}{c} \text{CuSO}_4 + 2\text{KI} \longrightarrow \text{CuI}_2 + \text{K}_2\text{SO}_4 \\ 2\text{CuI}_2 \longrightarrow \text{Cu}_2\text{I}_2 + \text{I}_2 \\ \text{I}_2 + 2\text{Na}_2\text{S}_2\text{O}_3 \longrightarrow \text{Na}_2\text{S}_4\text{O}_6 + 2\text{NaI} \end{array}$$

(xv) A mixture of silver chloride and sodium carbonate when heated forms silver carbonate which decomposes to give

$$2 \text{AgCl} + \text{Na}_2 \text{CO}_3 \xrightarrow{\Delta} \text{Ag}_2 \text{CO}_3 + 2 \text{NaCl}$$

$$\text{Ag}_2 \text{CO}_3 \xrightarrow{\Delta} 2 \text{Ag} + \text{CO}_2 + \frac{1}{2} \text{O}_2$$

(xvi) Iodine is liberated.

$$\begin{array}{c} \text{CaOCl}_2 + 2\text{CH}_3\text{COOH} \longrightarrow (\text{CH}_3\text{COO})_2\text{Ca} + \text{H}_2\text{O} + \text{Cl}_2 \\ 2\text{KI} + \text{Cl}_2 \longrightarrow 2\text{KCl} + \text{I}_2 \end{array}$$

(xvii) Xenon trioxide (an explosive) is formed.

$$XeF_6 + 3H_2O \longrightarrow XeO_3 + 6HF$$

(xviii) Yellow precipitate of potassium cobaltinitrite is formed. The following reactions occur.

$$\begin{array}{c} \text{CoCl}_2 + 2\text{KNO}_2 \longrightarrow \text{Co(NO}_2)_2 + 2\text{KCl} \\ \text{Co(NO}_2)_2 + 4\text{KNO}_2 \longrightarrow \text{K}_4\text{Co(NO}_2)_6 \\ \text{Pot. cobaltinitrite} \\ \text{KNO}_2 + \text{CH}_3\text{COOH} \longrightarrow \text{CH}_3\text{COOK} + \text{HNO}_2 \\ 2\text{HNO}_2 \longrightarrow 2\text{NO} + \text{H}_2\text{O} + [\text{O}] \\ 2\text{K}_4\text{Co(NO}_2)_6 + \text{H}_2\text{O} + [\text{O}] \longrightarrow 2\text{K}_3\text{Co(NO}_2)_6 + 2\text{KOH} \\ \text{Pot. cobaltinitrite} \end{array}$$

(xix) Ferric sulphate is reduced to ferrous sulphate with liberation of iodine.

$$Fe_2(SO_4)_3 + 2KI \longrightarrow 2FeSO_4 + K_2SO_4 + I_2$$

(xx) Copper in presence of moisture, oxygen and CO<sub>2</sub> of the atmosphere is reacted on the surface and a green layer of basic carbonate is deposited on its surface.

This is the method of preparation of methane.

(xxii) Xenon trioxide (an explosive substance) is formed.

$$3XeF_4 + 6H_2O \longrightarrow 2Xe + XeO_3 + \frac{3}{2}O_2 + 12HF$$

(xxiii) Ammonia and hypochlorous acid are formed.

$$NCl_3 + 3H_2O \longrightarrow NH_3 + 3HOCl$$

#### CONVERSION OF COMPOUNDS

- Q. 1. How will you bring about the following conversions?
  - (i) Sodium bicarbonate from sodium chloride.
  - (ii) Hypo from sodium sulphate.
  - (iii) Caustic soda from sodium carbonate.
  - (iv) Sodium bicarbonate from sodium carbonate.
  - (v) Sodium thiosulphate from sodium sulphite.
  - (vi) Hydrobromic acid from potassium bromide.
  - (vii) Chlorine from potassium chlorate.
  - (viii) Ammonia from nitre.
  - (ix) Nitric oxide from nitre.
  - (x) Oxygen from nitre.
- (i) This conversion is made in Solvay's process. Brine is first Ans. of all saturated by ammonia. By passing CO2 gas through ammonia-saturated brine, we get sodium bicarbonate.

$$NH_3 + H_2O + CO_2 \longrightarrow NH_4HCO_3$$
  
 $NH_4HCO_3 + NaCl \longrightarrow NaHCO_3 + NH_4Cl$ 

Note: On heating sodium bicarbonate, sodium carbonate is obtained.

$$2NaHCO_3 \xrightarrow{\Delta} Na_2CO_3 + H_2O + CO_2 \uparrow$$

(ii) On heating sodium sulphate with coke, we get sodium sulphide.

$$Na_2SO_4 + 4C \longrightarrow Na_2S + 4CO\uparrow$$

When SO<sub>2</sub> gas is passed through the mixture of Na<sub>2</sub>S and Na<sub>2</sub>CO<sub>3</sub>, we get hypo.

$$2Na_2S + Na_2CO_3 + 4SO_2 \longrightarrow 3Na_2S_2O_3 + CO_2 \uparrow$$
  
Sodium thiosulphate

(iii) By mixing Na<sub>2</sub>CO<sub>3</sub> with lime water, we get caustic soda along with white residue of CaCO<sub>3</sub>.

$$Na_2CO_3 + Ca(OH)_2 \longrightarrow 2NaOH + CaCO_3$$
(Caustic soda)

(iv) By passing CO2 gas through Na2CO3 in aqueous medium, we get sodium bicarbonate.

$$Na_2CO_3 + H_2O + CO_2 \longrightarrow 2NaHCO_3$$

(v) On boiling sodium sulphite with sulphur flower, we get sodium thiosulphate.

$$Na_2SO_3 + S \longrightarrow Na_2S_2O_3$$

(vi) On heating KBr with orthophosphoric acid, we get hydrobromic acid.

$$3KBr + H_3PO_4 \longrightarrow 3HBr + K_3PO_4$$

(vii) By heating solution of potassium chlorate with I2 and Cl2 is liberated.

$$2KClO_3 + I_2 \longrightarrow 2KlO_3 + Cl_2$$

Note: It is the only reaction in which Cl2 is displaced by iodine.

(viii) On heating nitre with Zn in presence of aqueous NaOH, reduction of nitre to ammonia takes place.

$$Zn + 2NaOH \longrightarrow Na_2ZnO_2 + 2[H]$$
  
 $KNO_3 + 8[H] \longrightarrow KOH + 2H_2O + NH_3$ 

(ix) Conversion of nitre into nitric oxide involves the following steps:

$$[KNO_3 + H_2SO_4 \longrightarrow KHSO_4 + HNO_3] \times 2$$

$$2HNO_3 \longrightarrow H_2O + 2NO + 3[O]$$

$$[2FeSO_4 + H_2SO_4 + [O] \longrightarrow Fe_2(SO_4)_3 + H_2O] \times 3$$

$$2KNO_3 + 6FeSO_4 + 5H_2SO_4 \longrightarrow 2KHSO_4 + 3Fe_2(SO_4)_3$$

$$+ 4H_2O + 2NO_4$$

(x) Thermal decomposition of nitre gives oxygen.  $2KNO_3 \xrightarrow{\Delta} 2KNO_2 + O_2$ 

$$2KNO_3 \xrightarrow{\Delta} 2KNO_2 + O_2$$

- Q. 2. How will you obtain:
  - (i) Silver from silver coin.
  - (ii) Silver oxide from silver nitrate.
  - (iii) Silver from silver sulphide.
  - (iv) Silver chloride from silver.
  - (v) Copper from copper sulphate.
  - (vi) Cupric chloride from cuprous carbonate.
  - (vii) Cuprous chloride from cupric chloride.
  - (viii) Cuprous chloride from copper sulphate.
  - (ix) Cuprous oxide from copper sulphate.
- (i) When silver coin is dissolved in HNO3, both Ag and Cu Ans. form their nitrates.

$$3Ag + 4HNO_3 \longrightarrow 3AgNO_3 + 2H_2O + NO\uparrow$$
  
 $3Cu + 8HNO_3 \longrightarrow 3Cu(NO_3)_2 + 4H_2O + 2NO\uparrow$   
Iding HCl to the solution, white precipitate of AgCl

On adding HCl to the solution, white precipitate of AgCl is formed.

$$\begin{array}{c} AgNO_3 + HCl \longrightarrow AgCl \downarrow + HNO_3 \\ (White ppt.) \end{array}$$

AgCl is reduced to metallic silver by zinc dust and HCl.

$$AgCl + [H] \xrightarrow{(Zn + dil. HCl)} Ag + HCl$$

(ii) Silver nitrate when dissolved in aqueous NaOH gives precipitate of Ag<sub>2</sub>O.

 $2AgNO_3 + 2NaOH \longrightarrow 2NaNO_3 + Ag_2O + H_2O$ 

(iii) We can obtain silver from Ag<sub>2</sub>S by cyanide process.

$$\begin{array}{c} Ag_2S + 4NaCN \longrightarrow 2Na[Ag(CN)_2] + Na_2S \\ 2Na[Ag(CN)_2] + Zn \longrightarrow Na_2[Zn(CN)_4] + 2Ag \end{array}$$

(iv) Ag dissolves in HNO3 to give AgNO3. On adding HCl to AgNO<sub>3</sub>, we get white precipitate of AgCl.

$$3Ag + 4HNO_3 \longrightarrow 3AgNO_3 + NO + 2H_2O$$

$$AgNO_3 + HCl \longrightarrow AgCl + HNO_3$$
(White ppt.)

(v) By adding iron turnings to aqueous solution of CuSO<sub>4</sub>, we get a deposition of copper metal.

$$CuSO_4 + Fe \longrightarrow Cu + FeSO_4$$

(vi) On adding dil. HCl to copper carbonate, we get cupric chloride.

$$CuCO_3 + 2HCl \longrightarrow CuCl_2 + H_2O + CO_2$$

(vii) 
$$SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2[H]$$
  
 $2CuCl_2 + 2[H] \longrightarrow Cu_2Cl_2 + 2HCl_3$ 

(viii) By passing SO<sub>2</sub> gas through the solution of CuSO<sub>4</sub> and NaCl in equimolar mixture, we get white precipitate of cuprous chloride.

$$SO_2 + 2H_2O \longrightarrow H_2SO_4 + 2[H]$$

$$2CuSO_4 + 2NaCl + 2[H] \longrightarrow Cu_2Cl_2 + 2NaHSO_4$$
(White ppt.)

(ix) When aqueous solution of CuSO<sub>4</sub> is heated with NaOH and glucose, we get brown precipitate of cuprous oxide.

$$\begin{array}{c} \text{CuSO}_4 + 2\text{NaOH} \longrightarrow \text{Cu(OH)}_2 + \text{Na}_2\text{SO}_4 \\ 2\text{Cu(OH)}_2 \longrightarrow \text{Cu}_2\text{O} + 2\text{H}_2\text{O} + [\text{O}] \\ \text{C}_6\text{H}_{12}\text{O}_6 + [\text{O}] \longrightarrow \text{C}_6\text{H}_{12}\text{O}_7 \\ \text{Gluconic acid} \end{array}$$

- Q. 3. Bring out the following interconversions:
  - (a) Carbon monoxide into carbon.
  - (b) Carbon dioxide to carbon.
  - (c) Carbon monoxide from water gas.
  - (d) Red lead to litharge.
  - (e) Lead to red lead.
  - (f) Litharge to red lead.

(a) By passing CO through red hot CuO, it is converted to carbon Ans. dioxide.

$$CuO + CO \longrightarrow Cu + CO_2$$

When burning magnesium ribbon is placed in a gas jar of CO<sub>2</sub>, we get carbon.

$$2Mg + CO_2 \longrightarrow 2MgO + C$$

- (b) See above part.
- (c) By passing water gas over nickel, CO combines to nickel carbonyl.

$$Ni + 4[CO + H_2] \longrightarrow Ni(CO)_4 + 4H_2\uparrow$$

Decomposition of nickel carbonyl gives CO(g).

$$Ni(CO)_4 \xrightarrow{200^{\circ}C} Ni + 4CO^{\uparrow}$$

(d) By heating red lead at 470°C, we get litharge.

$$\begin{array}{ccc}
2\text{Pb}_3\text{O}_4 & \xrightarrow{470^{\circ}\text{C}} & \text{6PbO} + \text{O}_2 \\
\text{Red lead} & & \text{Litharge}
\end{array}$$

(e) By heating metallic lead in air, oxidation takes place to give red lead.

$$\begin{array}{c} \text{2Pb + O}_2 \longrightarrow \text{2PbO} \\ \text{6PbO + O}_2 \xrightarrow{340^{\circ}\text{C}} \text{2Pb}_3\text{O}_4 \\ \text{Red lead} \end{array}$$

(f) Litharge on heating in air at a high temperature (340°C) gives red lead.

- Q. 4. How will you obtain:
  - (a) Microcosmic salt from disodium hydrogen phosphate.
  - (b) Sodium metaphosphate from microcosmic salt.
  - (c) Barium nitrate from barium sulphate.
  - (d) Barium chloride from barium nitrate.
  - (e) Barium chloride from barium sulphate.
  - (f) Bleaching powder from lime.
  - (g) Quicklime from calcium chloride.
  - (h) Zinc nitrate from zinc chloride.
  - Anhydrous magnesium chloride from magnesium sulphate.
  - (i) Zinc sulphide from zinc chloride.
  - (k) Calomel from mercury.
  - (1) Corrosive sublimate from calomel.
  - (m) Mercury from calomel.
  - (n) Calomel from corrosive sublimate.
- Equal amounts of ammonium chloride and disodium hydrogen Ans. phosphate are dissolved in hot water. On crystallisation, crystals of microcosmic salt are obtained.

$$Na_2HPO_4 + NH_4Cl \longrightarrow NaNH_4HPO_4 + NaCl$$

$$\downarrow^{4H_2O}$$

$$NaNH_4HPO_4 \cdot 4H_2O$$

Microcosmic salt

(b) On heating microcosmic salt, sodium metaphosphate is

$$NaNH_4HPO_4 \cdot 4H_2O \xrightarrow{\Delta} NaPO_3 + NH_3 + 5H_2O$$

(c) Barium sulphate is heated with carbon to get barium sulphide. This is dissolved in dilute HNO3 and the solution is put to crystallisation.

$$BaSO_4 + 4C \longrightarrow BaS + 4CO$$
  
 $BaS + 2HNO_3 \longrightarrow Ba(NO_3)_2 + H_2S$ 

(d) Barium carbonate is first precipitated by adding ammonium carbonate solution to barium nitrate solution. The precipitate is then dissolved in dilute HCl and solution is crystallised to get crystals of barium chloride.

$$Ba(NO_3)_2 + (NH_4)_2CO_3 \longrightarrow BaCO_3 + 2NH_4NO_3$$

$$BaCO_3 + 2HCI \longrightarrow BaCl_2 + H_2O + CO_2$$

 $BaSO_4 + 4C \longrightarrow BaS + 4CO$ 

BaS is dissolved in dilute HCl and the solution is crystallised to get BaCl2 crystals.

(f) Lime is treated with water to get Ca(OH)2. On passing Cl2 over dry Ca(OH)2, bleaching powder is formed.

$$\begin{array}{c} \text{CaO} + \text{H}_2\text{O} \longrightarrow \text{Ca(OH)}_2 \\ \text{Ca(OH)}_2 + \text{Cl}_2 \longrightarrow \text{CaOCl}_2 + \text{H}_2\text{O} \end{array}$$

(g) Calcium chloride is dissolved in water. Ammonium carbonate is added to precipitate calcium carbonate. The precipitate on strong heating gives quicklime.

CaCl<sub>2</sub> + (NH<sub>4</sub>)<sub>2</sub>CO<sub>3</sub> 
$$\longrightarrow$$
 CaCO<sub>3</sub> + 2NH<sub>4</sub>Cl
$$CaCO_3 \xrightarrow{\Delta} CaO + CO_2$$

(h) Zinc chloride solution is treated with sodium bicarbonate solution when zinc carbonate gets precipitated. The precipitate is dissolved in dilute HNO3 and the solution is crystallised to get crystals of zinc nitrate.

$$ZnCl_2 + 2NaHCO_3 \longrightarrow ZnCO_3 + 2NaCl + H_2O + CO_2$$
  
 $ZnCO_3 + 2HNO_3 \longrightarrow Zn(NO_3)_2 + H_2O + CO_2$ 

(i) Magnesium sulphate solution is treated with sodium bicarbonate solution when magnesium carbonate gets precipitated.

$$MgSO_4 + 2NaHCO_3 \longrightarrow MgCO_3 + Na_2SO_4 + H_2CO_3$$

+ H<sub>2</sub>O +CO<sub>2</sub>

The precipitate is dissolved in small quantity of dilute HCl. The solution is concentrated and treated with conc. NH<sub>4</sub>Cl solution. On evaporation, a double salt MgCl<sub>2</sub>·NH<sub>4</sub>Cl·6H<sub>2</sub>O is formed. The crystals on heating give anhydrous MgCl<sub>2</sub>.

$$MgCO_3 + 2HCl \longrightarrow MgCl_2 + H_2O + CO_2$$

$$MgCl_2 + NH_4Cl + 6H_2O \longrightarrow MgCl_2 \cdot NH_4Cl \cdot 6H_2O$$

$$MgCl_2\cdot NH_4Cl\cdot 6H_2O \longrightarrow MgCl_2 + NH_3 + HCl + 6H_2O$$

(j) ZnCl2 is dissolved in water. NH4Cl and NH4OH are added to solution and H2S gas is passed. ZnS gets precipitated which is filtered.

$$ZnCl_2 + 2NH_4OH + H_2S \longrightarrow ZnS + 2NH_4Cl + 2H_2O$$

(k) Mercury is dissolved in conc. H<sub>2</sub>SO<sub>4</sub> and the solution is evaporated to get solid HgSO<sub>4</sub>. The solid is grinded with NaCl and Hg and the mixture is heated. Mercurous chloride sublimes and collected.

$$Hg + 2H_2SO_4 \longrightarrow HgSO_4 + SO_2 + 2H_2O$$
  
 $HgSO_4 + 2NaCl + Hg \longrightarrow Hg_2Cl_2 + Na_2SO_4$ 

(1) Calomel is dissolved in aqua-regia and the solution is put to crystallisation when crystals of corrosive sublimate are obtained.

$$HNO_3 + 3HCl \longrightarrow NOCl + 2Cl + 2H_2O$$
  
 $Hg_2Cl_2 + 2Cl \longrightarrow 2HgCl_2$ 

(m) Hg<sub>2</sub>Cl<sub>2</sub> solution is reduced by stannous chloride solution into mercury.

$$Hg_2Cl_2 + SnCl_2 \longrightarrow 2Hg + SnCl_4$$

(n) Calomel is obtained by passing sulphur dioxide through the solution of mercuric chloride.

$$2HgCl_2 + 2H_2O + SO_2 \longrightarrow Hg_2Cl_2 + H_2SO_4 + 2HCl$$

- O. 5. Show by balanced equations how would you obtain from HNO3:
  - (a) NO, (b) NO<sub>2</sub>, (c)  $N_2O$ ,

 $S + 2HNO_3(conc.) \longrightarrow H_2SO_4 + 2NO\uparrow$ (a) Ans.

(b) 
$$C + 4HNO_3(conc.) \longrightarrow CO_2 \uparrow + 4NO_2 \uparrow + 2H_2O$$

- $4Cu + 10HNO_3(dil.) \longrightarrow 4Cu(NO_3)_2 + 5H_2O + N_2O\uparrow$
- (d)  $5Cu(red hot) + 2HNO_3(conc.) \longrightarrow 5CuO + N_2 \uparrow + H_2O$
- Q. 6. Give the chemical equations for synthesis of the following
- compounds using corresponding elemental halogen:
  - (d) KBrO<sub>3</sub>, (a)  $Br_2O$ , (b)  $BrO_3$ , (c)  $OF_2$ ,
  - (f) Cl<sub>2</sub>O, (g)  $I_2O_5$ , (h)  $HClO_4$ .
- $2Br_2 + HgO \longrightarrow Br_2O + HgBr_2$ Ans.

(b) 
$$\frac{1}{2}Br_2 + O_3 \xrightarrow{0^{\circ}C} BrO_3$$

(c) 
$$2F_2 + 2NaOH \longrightarrow 2NaF + OF_2 + H_2O$$

- (d)  $3Br_2 + 6KOH \longrightarrow 5KBr + KBrO_3 + 3H_2O$
- (e)  $3Cl_2 + 6NaOH \longrightarrow 5NaCl + NaClO_3 + 3H_2O$

$$2H^{+} + 2ClO_{3}^{-} + \begin{matrix} COOH \\ COOH \end{matrix} \longrightarrow 2ClO_{2} + 2CO_{2} + 2H_{2}O$$

- $2Cl_2 + HgO \longrightarrow Cl_2O + HgCl_2$ (f)
- $I_2 + 10HNO_3 \longrightarrow 2HIO_3 + 10NO_2 + 4H_2O$

 $\begin{array}{ccc} & 2HIO_3 \longrightarrow & H_2O \,+\, I_2O_5 \\ \text{(h)} & 3Cl_2 \,+\, 6NaOH \longrightarrow & 5NaCl \,+\, NaClO_3 \,+\, 3H_2O \end{array}$ 

$$4\text{NaClO}_3 \xrightarrow{\Delta} \text{NaCl} + 3\text{NaClO}_4$$

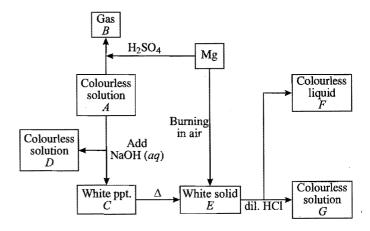

Q.7. How would you obtain pure copper oxide from brass?

Ans. Brass (containing Cu and Zn) 
$$\bigcirc$$
 Conc. HNO<sub>3</sub>  $[Cu(NO_3)_2 + Zn(NO_3)_2]$ 

Blue coloured precipitate of Cu(OH)2

CuO (Cupric oxide)

Q. 8. Identify 'A' to 'G' in the following road map diagram. Explain the reactions involved.

**Ans.** (A):  $MgSO_4$ , (B):  $H_2$ , (C):  $Mg(OH)_2$ , (D):  $Na_2SO_4$ , (E): MgO, (F): water, (G): MgCl<sub>2</sub>.

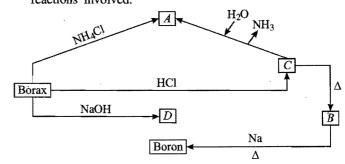

$$\begin{array}{c} \text{Mg} + \text{H}_2\text{SO}_4 & \longrightarrow & \text{MgSO}_4 + \text{H}_2 \uparrow \\ & [A] & [B] \end{array}$$

$$\begin{array}{c} \text{MgSO}_4 + 2\text{NaOH} & \longrightarrow & \text{Mg(OH)}_2 + \text{Na}_2\text{SO}_4 \\ & [C] & [D] \end{array}$$

$$\begin{array}{c} \text{Mg(OH)}_2 & \stackrel{\Delta}{\longrightarrow} & \text{MgO} \\ & [E] \end{array}$$

$$\text{MgO} + 2\text{HCI} & \longrightarrow & \text{MgCl}_2 + \text{H}_2\text{O} \end{array}$$

Q. 9. Properties of borax are represented by the following road map. Identify the compounds 'A' to 'D' and explain the reactions involved.

**Ans.** (A): BN, (B):  $B_2O_3$ , (C):  $H_3BO_3$ , (D):  $NaBO_2$ . Reactions involved are:

$$Na_2B_4O_7 + 4NH_4C1 \longrightarrow 4BN + 2NaC1 + 7H_2O + 2HC1$$

$$[A]$$
 $BN + 3H_2O \longrightarrow H_3BO_3 + NH_3$ 

$$[C]$$

$$\begin{array}{c} \text{Na}_2\text{B}_4\text{O}_7 + 2\text{HCl} + 5\text{H}_2\text{O} \longrightarrow 4\text{H}_3\text{BO}_3 + 2\text{NaCl} \\ \text{Na}_2\text{B}_4\text{O}_7 + 4\text{NaOH} \longrightarrow 8\text{NaBO}_2 + 2\text{H}_2\text{O} \\ 2\text{H}_3\text{BO}_3 \stackrel{\Delta}{\longrightarrow} \text{B}_2\text{O}_3 + 3\text{H}_2\text{O} \\ & \text{B}_2\text{O}_3 + 6\text{Na} \stackrel{\Delta}{\longrightarrow} 2\text{B} + 3\text{Na}_2\text{O} \end{array}$$

Q.10. Complete the following road map:

$$H_2C_2O_4 \xrightarrow{\text{Conc.} H_2SO_4} (A) + (B) + (C)$$
 $Gas Gas Liquio$ 

Gas (A) burns with blue flame and converts nickel into a gas.

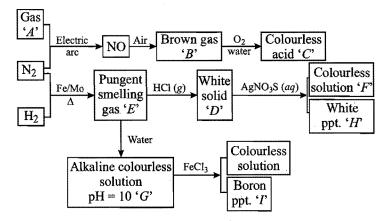

Gas (B) turns lime water milky. Liquid (C) produces blue colour when comes in contact with anhydrous copper sulphate.

$$(A) + \operatorname{Cl}_2 \longrightarrow (D) \xrightarrow{\operatorname{NH}_3} (E)$$

$$(B) \xrightarrow{\operatorname{NH}_3} \xrightarrow{\operatorname{Heat}}$$

**Ans.** (A):CO, (B):CO<sub>2</sub>, (C):H<sub>2</sub>O, (D):COCl<sub>2</sub>, (E):NH<sub>2</sub>CONH<sub>2</sub>.

**Q.11.** Identify the missing chemicals 'A' to T.

**Ans.**  $(A): O_2, (B): NO_2, (C): HNO_3, (D): NH_4Cl, (E): NH_3,$ 

 $(F): NH_4NO_3, (G): NH_4OH, (H): AgCl, (I): Fe(OH)_3.$ 

#### Q.12. How will you obtain:

- (a) Anhydrous aluminium chloride from alumina.
- (b) Aluminium sulphate from common alum.
- (c) Ammonium sulphate from ammonium chloride.
- (d) Phosphorus from bone ash.
- (e) Orthophosphoric acid (pyrophosphoric acid/metaphosphoric acid) from phosphorus.
- (f) Sulphur from  $H_2S$  or  $SO_2$ .
- (g) HBr from bromine.
- (h) Ferric sulphate from ferrous sulphate.
- (i) Ferric chloride from ferrous sulphate.
- (i) Ferrous sulphate from Mohr's salt.

Ans. (a) By heating a mixture of alumina and carbon in an atmosphere of chlorine, anhydrous aluminium chloride is obtained.

$$Al_2O_3 + 3C + 3Cl_2 \longrightarrow 2AlCl_3 + 3CO$$
 $Vapours$ 
 $Cooled$  Solid

(b) NH<sub>4</sub>OH is added to alum solution when aluminium hydroxide gets precipitated. The precipitate is dissolved in dilute H<sub>2</sub>SO<sub>4</sub>. The solution on crystallisation gives crystals of aluminium sulphate.

- (c) Ammonium chloride is treated with NaOH. NH<sub>3</sub> is evolved which is absorbed in dilute H<sub>2</sub>SO<sub>4</sub>. The solution on evaporation gives crystals of ammonium sulphate.
- (d) Bone ash on heating with coke and sand in an electric furnace at 1500°C gives vapours of phosphorus which are condensed in water.

$$Ca_3(PO_4)_2 + 3SiO_2 + 5C \longrightarrow 3CaSiO_3 + 2P + 5CO$$

(e) Phosphorus on heating with conc. HNO<sub>3</sub> forms orthophosphoric acid. Orthophosphoric acid when heated at specific temperature forms other oxy acids.

(f) H<sub>2</sub>S by oxidation gives sulphur.

$$H_2S + Cl_2 \longrightarrow 2HCl + S$$
  
 $H_2S + 2HNO_3 \longrightarrow 2NO_2 + 2H_2O + S$ 

On burning magnesium in SO2, S is obtained.

$$2Mg + SO_2 \longrightarrow 2MgO + S$$

$$\downarrow HCI$$

$$MgCl_2 \text{ (soluble)}$$
 $2H_2S + SO_2 \longrightarrow 2H_2O + 3S$ 

(g) Bromine combines with red phosphorus kept in water.

$$2P + 3Br_2 \longrightarrow 2PBr_3$$

Phosphorus bromide immediately undergoes hydrolysis giving HBr.

$$PBr_3 + 3H_2O \longrightarrow H_3PO_3 + 3HBr$$

(h) Ferrous sulphate is heated with concentrated sulphuric acid. The solution on concentration gives ferric sulphate crystals.

$$\frac{\text{H}_2\text{SO}_4 \longrightarrow \text{H}_2\text{O} + \text{SO}_2 + [\text{O}]}{2\text{FeSO}_4 + \text{H}_2\text{SO}_4 + [\text{O}] \longrightarrow \text{Fe}_2(\text{SO}_4)_3 + \text{H}_2\text{O}}{2\text{FeSO}_4 + 2\text{H}_2\text{SO}_4 \longrightarrow \text{Fe}_2(\text{SO}_4)_3 + \text{SO}_2 + 2\text{H}_2\text{O}}$$

(i) Ferrous sulphate is first converted into ferric sulphate. Ammonium hydroxide is added to ferric sulphate solution when a brown precipitate of ferric hydroxide is obtained. The precipitate is dissolved in dilute HCl and the solution on crystallisation gives ferric chloride crystals.

$$Fe_2(SO_4)_3 + 6NH_4OH \longrightarrow 2Fe(OH)_3 + 3(NH_4)_2SO_4$$

$$Fe(OH)_3 + 3HCl \longrightarrow FeCl_3 + 3H_2O$$

(j) Mohr's salt solution is treated with NaOH solution. A precipitate of ferrous hydroxide is formed. The precipitate is dissolved in dilute  $\rm H_2SO_4$  and the solution is put to crystallisation when crystals of ferrous sulphate are obtained.

$$\begin{split} \text{FeSO}_4 \cdot (\text{NH}_4)_2 &\text{SO}_4 \cdot 6\text{H}_2\text{O} + 2\text{NaOH} \longrightarrow &\text{Fe}(\text{OH})_2 \\ &+ \text{Na}_2 \text{SO}_4 + (\text{NH}_4)_2 \text{SO}_4 + 6\text{H}_2\text{O} \\ \text{Fe}(\text{OH})_2 + \text{H}_2 \text{SO}_4 \longrightarrow &\text{FeSO}_4 + 2\dot{\text{H}}_2\text{O} \end{split}$$

Q.13. Identify the following:

$$Na_2CO_3 \xrightarrow{SO_2} A \xrightarrow{Na_2CO_3} B \xrightarrow{S} C \xrightarrow{I_2} D$$

[HT 2003]

$$\begin{array}{c} \text{Na}_2\text{CO}_3 + 2\text{SO}_2 + \text{H}_2\text{O} \longrightarrow 2\text{NaHSO}_3 + \text{CO}_2 \\ \text{2NaHSO}_3 + \text{Na}_2\text{CO}_3 \longrightarrow 2\text{Na}_2\text{SO}_3 + \text{H}_2\text{O} + \text{CO}_2 \\ \text{(B)} \\ \text{Na}_2\text{SO}_3 + \text{S} \longrightarrow \text{Na}_2\text{S}_2\text{O}_3 \text{ (Hypo)} \\ \text{(C)} \\ \text{2Na}_2\text{S}_2\text{O}_3 + \text{I}_2 \longrightarrow \text{Na}_2\text{S}_4\text{O}_6 + 2\text{NaI} \\ \text{(D)} \end{array}$$

Q.14. Identify the following:

$$Si + CH_3Cl \xrightarrow{Cu \text{ powder} \atop 570 \text{ K}} (A) \xrightarrow{H_2O} (B) \xrightarrow{Polymerisation} Silicon$$

$$\downarrow O_2$$

(C) 
$$\xrightarrow{\text{Excess of coke}}$$
 (D)

Ans. Si + 2CH<sub>3</sub>Cl 
$$\xrightarrow{\text{Cu powder}}$$
 (CH<sub>3</sub>)<sub>2</sub>SiCl<sub>2</sub>
(A)

Polymeri- $(CH_3)_2SiCl_2 + H_2O \longrightarrow (CH_3)_2Si(OH)_2 \xrightarrow{sation} Silicon$ (B) Dimethyl silandiol

$$Si + O_2 \xrightarrow{Burns} SiO_2$$
(C)

$$SiO_2 + 3C \xrightarrow{Arc} SiC + 2CO$$

$$Carborundum$$

**Q.15.** On the basis of following reactions, identify (A), (B), (C)and (D) and write down their chemical formulae.

(i) 
$$(A) + Zn \xrightarrow{\text{Heat}} (B)$$
 gas

(ii) 
$$(A) + (C) \xrightarrow{\text{Heat}} PH_3$$

(iii) 
$$(A) + NH_4Cl \xrightarrow{Heat} (D)$$
 gas

(i) (A) is sodium hydroxide.

$$2NaOH + Zn \longrightarrow Na_2ZnO_2 + H_2$$
(B)

(ii) (C) is phosphorus.

$$3NaOH + 4P + 3H_2O \longrightarrow 3NaH_2PO_2 + PH_3$$

(iii) (D) is ammonia gas.

$$NH_4Cl + NaOH \longrightarrow NH_3 + NaCl + H_2O$$

Q.16. Explain the following reactions:

(a) Metal (M) 
$$\xrightarrow{\text{Dissolves}}$$
 Pale green soln.  $\xrightarrow{\text{Add}}$ 

Whitish precipitate quickly turning brown  $\xrightarrow{HCl}$ 

dissolves giving yellow soln.

(b) Black substance 
$$\xrightarrow{\text{Heated in} \atop \text{air with Na}_2\text{CO}_3}$$
 dark mass  $\xrightarrow{\text{Extracted} \atop \text{with water}}$  green soln.  $\xrightarrow{\text{Chlorine} \atop \text{Water}}$  pink soln.

Ans. (a) Metal (M) is iron. Fe + 
$$H_2SO_4 \longrightarrow FeSO_4$$
,  
 $FeSO_4 + NaOH \longrightarrow Fe(OH)_2 \longrightarrow Fe(OH)_3 \xrightarrow{HCl} FeCl_3$   
Yellow soln.

(b) 
$$MnO_2 + Na_2CO_3 + O_2 \xrightarrow{H_2O} Na_2MnO_4 \xrightarrow{Cl_2} NaMnO_4$$
Black
Black
Substance

Green soln.

Pink soln.

#### Type 4: Assertion-Reason type

The following questions consist of two statements each printed as Assertion (A) and Reason (R). Use the following key to choose the correct answer.

- (a) If both (A) and (R) are correct and (R) is the correct explanation of (A).
- (b) If both (A) and (R) are correct but (R) is not the correct explanation of (A).
- (c) If (A) is correct but (R) is incorrect.
- (d) If (A) is incorrect but (R) is correct.
- (e) If both (A) and (R) are incorrect.
- 1. (A) Photochemical smog is produced by nitrogen oxides.
  - (R) Vehicular pollution is a major source of nitrogen oxides.
- (A) Lead tetraiodide (PbI<sub>4</sub>) is a stable compound.
  - (R) Iodide stabilizes higher oxidation state.

- 3. (A) HClO<sub>4</sub> is a stronger acid than HClO<sub>3</sub>.
  - (R) Oxidation states of Cl in  $HClO_4$  is + 7 and in  $HClO_3$ , it is + 5.
- 4. (A) The free gaseous chromium atom has six unpaired electrons.
  - (R) Half filled s-orbital has greater stability.
- 5. (A) Density of magnesium is less than of calcium.
  - (R) It is due to the presence of 3d-orbital.
- 6. (A) The first ionisation energy of Be is greater than that of B.
  - (R) 2p-orbital is lower in energy than 2s-orbital.
- 7. (A) F-atom has a less electron affinity than Cl-atom.
  - (R) Additional electrons are repelled more effectively by 3p electrons in Cl than by 2p electrons in F-atom.
- 3. (A) Sigma ( $\sigma$ ) is a strong bond while pi ( $\pi$ ) is a weak bond.
  - (R) Atoms rotate freely about pi  $(\pi)$  bond.
- (A) Stannous chloride is a powerful oxidising agent which oxidises mercuric chloride to metallic mercury.

- (R) Stannous chloride gives grey precipitate with mercuric chloride but stannic chloride does not do so.
- 10. (A) The fluorine has lower reactivity.
  - (R) F—F bond has low bond dissociation energy.
- 11. (A) Potassium and caesium are used in photoelectric cells.
  - (R) Potassium and caesium emit electrons on exposure to light.
- 12. (A) Diamond is a bad conductor.
  - (R) Graphite is a good conductor.
- 13. (A) Carbon tetrachloride is resistant towards hydrolysis, whereas silicon tetrachloride is readily hydrolysed.
  - (R) Silicon has bigger size and can accommodate large number of water molecules around itself.
- 14. (A) Diborane is an electron deficient.
  - (R) There are no enough valence electrons to form expected number of covalent bonds.
- 15. (A) The bond order in a molecule can have any value, positive or negative, integral or fractional or zero.
  - (R) The bond order of a molecule depends upon the number of electrons in the bonding and antibonding molecular orbitals.
- 16. (A) Chlorine and sulphur dioxide both are bleaching agents.
  - (R) The bleaching action of chlorine and sulphur dioxide is performed through the process of oxidation.
- (A) Copper reacts with hydrochloric acid and liberates hydrogen from the solution of dilute hydrochloric acid.
  - (R) Hydrogen is below copper in electrochemical series.
- 18. (A) Bond order can assume any value including zero.
  - (R) Higher the bond order, shorter is the bond length and greater is the bond energy.
- 19. (A) Beryllium and magnesium impart colour to the flame.
  - (R) Beryllium and magnesium both have big size and lower ionisation energies.
- (A) Carbon forms covalent compounds whereas lead forms ionic compounds.
  - (R) Carbon can lose electrons to form C4+ while lead cannot.
- 21. (A) The melting and boiling points of alkali metals are very high.
  - (R) Alkali metals have large size molecules.
- 22. (A) Molecular weight of oxygen is 16.
  - (R) Atomic weight of oxygen is 16.
- (A) Copper sulphate solution on reacting with excess of potassium cyanide solution gives K<sub>3</sub>[Cu(CN)<sub>4</sub>].
  - (R) Cupric state of copper is more stable than cuprous state in the complex.
- 24. (A) Alkali metals impart colour to the flame.
  - (R) Their ionisation energies are low.
- 25. (A) Bond angle in H<sub>2</sub>O is more than in NH<sub>3</sub>.
  - (R) Lone pair-lone pair repulsion > lone pair-bond pair repulsion.
- 26. (A) Bond dissociation energy of fluorine is less than that of chlorine.
  - (R) Electronegativity of fluorine is much higher than chlorine.
- (A) Potassium carbonate cannot be manufactured by a process similar to Solvay's process.
  - (R) Potassium hydrogen carbonate is soluble in water.
- 28. (A) Dioxygen is paramagnetic in nature.
  - (R) Oxygen is found in free state only.
- 29. (A) NO<sub>3</sub> is planar while NH<sub>3</sub> is pyramidal.
  - (R) N in NO<sub>3</sub> has  $sp^2$  and in NH<sub>3</sub> has  $sp^3$  hybridisation.
- 30. (A) Carbonates and hydroxides are concentrated by froth floatation
  - (R) In froth floatation process pine oil is used because it preferentially wets the ore particles.
- 31. (A) D<sub>2</sub>O is called hard water.
  - (R) It's degree of dissociation is high.
- (A) The alkali metals can form ionic hydrides which contain the hydride ion, H<sup>-</sup>.

- chloride (R) The alkali metals have low electronegativity. Their hydrides conduct electricity when fused and liberate hydrogen at the anode.
  - 33. (A) Na<sub>2</sub>SO<sub>4</sub> is soluble in water while BaSO<sub>4</sub> is insoluble.
    - (R) Lattice energy of barium sulphate exceeds its hydration energy.
  - 34. (A) H<sub>2</sub>O is the only hydride of chalcogens which is liquid at ordinary temperature.
    - (R) In ice each O-atom is surrounded by two covalent bonds and two H-bonds.
  - 35. (A) Xenon forms fluorides.
    - (R) Because 5d-orbitals are available for valence shell expansion.
  - 36. (A) Pb<sup>4+</sup>can be reduced easily to Pb<sup>2+</sup>.
    - (R) The size of Pb2+ is bigger than Pb4+ as a second of the size of Pb2+ is bigger than Pb4+ as a second of the size of Pb2+ is bigger than Pb4+ as a second of the size of Pb2+ is bigger than Pb4+ as a second of the size of Pb2+ is bigger than Pb4+ as a second of the size of Pb2+ is bigger than Pb4+ as a second of the size of Pb2+ is bigger than Pb4+ as a second of the size o
  - 37. (A) CO<sub>2</sub> and SiO<sub>2</sub> have same physical state at room temperature.
    - (R) CO₂ contains C=O bonds but SiO₂ does not contain S=O bonds.
  - 38. (A) Tungsten has a very high melting point.
    - (R) Tungsten is a covalent compound.
  - 39. (A) Iron compounds are paramagnetic and coloured.
    - (R) Iron in Fe<sup>2+</sup> or Fe<sup>3+</sup> does not contain unpaired electrons.
  - 40. (A) Every d-block series consists ten elements.
    - (R) Because, the maximum capacity of d-subshell is of ten electrons, d-subshell is gradually filled up.
  - 41. (A) Sulphuric acid is more viscous than water.
    - (R) In H<sub>2</sub>SO<sub>4</sub>, the S-atom exhibits its highest oxidation state.
  - 42. (A) Sulphur dioxide can act as oxidising as well as reducing agent.
    - (R) In sulphur dioxide S assumes  $sp^3d$  hybrid states.
  - 43. (A) H<sub>3</sub>PO<sub>3</sub> is a monobasic acid.
    - (R) Two H-atoms are directly attached to P.
  - 44. (A) Carbon monoxide reacts with nickel to form nickel carbonyl.
    - (R) Carbon monoxide is an acidic oxide.
  - 45. (A) Zinc, cadmium and mercury do not show characteristic properties of transition metals.
    - (R) In these metals outermost shell is completely filled.
  - 46. (A) FeS<sub>2</sub> is known as fool's gold.
    - (R) FeS<sub>2</sub> has yellow metallic appearance.
  - 47. (A) Lanthanides are generally diamagnetic.
    - (R) Lanthanides have the tendency to attain +3 oxidation state.
  - 48. (A) EAN of Fe in its complexes is always 36.
    - (R) Oxidation state of Fe in Fe(CO)<sub>5</sub> is +2.
  - 49. (A) Chelates are less stable than ordinary coordination compounds.
    - (R) Chelates can be formed by bidentate ligands.
  - 50. (A) Ionic compounds tend to be non-volatile.
    - (R) Ionic compounds are bad conductors in solid state.
  - (A) Reaction of SO<sub>2</sub> and H<sub>2</sub>S in presence of Fe<sub>2</sub>O<sub>3</sub> catalyst gives elemental sulphur.
    - (R) SO<sub>2</sub> is a reducing agent.
  - 52. (A) Addition of NH<sub>4</sub>OH to an aqueous solution of BaCl<sub>2</sub> in presence of NH<sub>4</sub>Cl(excess) precipitates Ba(OH)<sub>2</sub>.
    - (R) Ba(OH)<sub>2</sub> is insoluble in water.
  - 53. (A) First ionisation energy of fluorine is lower than oxygen.
    - (R) Across a period effective nuclear charge decreases.
  - 54. (A) Borax bead test is not suitable for Al(III).
    - (R) Al<sub>2</sub>O<sub>3</sub> is insoluble in water.
  - 55. (A) Potassium ferricyanide is paramagnetic while potassium ferrocyanide is diamagnetic.
    - (R) Crystal field splitting in ferrocyanide ion is greater than in ferricyanide ion.
  - 56. (A) Molecular nitrogen is less reactive than molecular oxygen.
    - (R) The bond length of N<sub>2</sub> is shorter than that of oxygen.
  - 57. (A) K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> is used as primary standard in volumetric analysis.
    - (R) It has a good solubility in water.

Type 5: Thought Type Questions

#### Thought 1

In the modern periodic table, the elements are placed in order of increasing atomic number. The long form of periodic table shows all the elements in numerical order. The start of a new period always corresponds to the introduction of the first electron into the s-orbital of a new principal quantum number. The number of elements in each period corresponds to the number of electrons required to fill the orbitals according to aufbau principle.

1s, 2s2p, 3s3p, 4s3d4p, 5s4d5p, 6s4f5d6p, 7s5f6d7p.

The main groups correspond to elements in which s and p orbitals are being filled. The transition elements are those in which d-orbitals are being filled. Each group contains elements of similar electronic configuration. According to the recommendations of IUPAC, the groups of elements are numbered from 1 to 18. The elements corresponding to filling of 4f-orbitals are called lanthanons and those corresponding to the filling of 5f-orbitals are called actinons. These elements are accommodated into two separate horizontal rows below the table.

There are only 81 stable elements known. For these elements, one or more isotopes do not undergo spontaneous radioactive decay. No stable isotope exists for any element above bismuth. Two elements, uranium and thorium, for which only radioactive isotopes exist, are found quite abundantly on earth because the half-lives of some of their isotopes are almost as great as the age of earth.

- ..... periods and ..... groups are there in the long form of the periodic table.
  - (a) 7 and 16
- (b) 7 and 9
- (c) 7 and 18
- (d) 9 and 9
- Configuration of the final elements of 3d, 4d, 5d series respectively are:
  - (a)  $3d^54s^2$ ,  $4d^{10}5s^2$ ,  $5d^{10}6s^2$
  - (b)  $3d^{10}4s^2$ ,  $4d^{10}5s^2$ ,  $5d^{10}6s^2$
  - (c)  $3d^{10}4s^2$ ,  $4d^{10}5s^1$ ,  $5d^{10}6s^1$
  - (d)  $3d^94s^2$ ,  $4d^{10}5s^2$ ,  $5d^{10}6s^1$
- Two elements, one belonging to 4d series and other to lanthanon series, which are not stable and not found in nature and have been discovered by artificial means are:
  - (a) Tc and Eu
- (b) Nb and Gd
- (c) Y and Dy
- (d) Tc and Pm
- Outermost configuration of two p-block elements A and B are  $ns^2np^1$  and  $ns^2np^6$  respectively. The elements are if n=4:

- (a) A = Ga, B = Xe
- (b) A = In, B = Xe
- (c) A = Ga, B = Kr
- (d) A = Zn, B = Kr
- General outermost electronic configuration of the elements situated above and below X (Atomic number = 50) would
  - (a)  $ns^2np^2$
- (c)  $ns^2np^4$
- (b)  $ns^2np^3$ (d)  $ns^2np^5$

#### Thought 2

Quantum mechanical calculations show that mathematical mixing of certain combinations of orbitals in a given atom gives rise to new atomic orbitals. The spatial orientations of these new orbitals lead to more stable bonds and are consistent with the observed molecular shapes. The process of orbital mixing is called hybridization and the new atomic orbitals are called hybrid orbitals. Two key points about the number and type of the hybrid orbitals are that:

- (i) The number of hybrid orbitals obtained equals the number of atomic orbitals mixed.
- (ii) The type of hybrid orbitals obtained varies with the type of atomic orbitals mixed.

The following two methods are used to know about the type of hybridization in the molecule.

Method 1: Count number of atoms directly attached to central atom + lone pairs + single electrons

Method 2 : Count  $\sigma$  bonds + coordinate bonds + lone pairs + single electrons

If the number comes out to be:

- $5 \longrightarrow sp^3d$  hybridization  $2 \longrightarrow sp$  hybridization
- $3 \longrightarrow sp^2 \text{ hybridization}$   $3 \longrightarrow sp^2 \text{ hybridization}$   $4 \longrightarrow sp^3d^2 \text{ hybridization}$  $d^2sp^3$  hybridization  $4 \longrightarrow sp^3$  hybridization

dsp<sup>2</sup> hybridization

1. The hybridization scheme for central atom includes a d-orbital contribution in:

(a)  $I_3^-$ 

(b) PCl<sub>3</sub>

(c)  $NO_3$ 

- (d) H<sub>2</sub>Se
- 2. Hybrid states of Xe in XeF<sub>2</sub>, XeF<sub>4</sub> and XeF<sub>6</sub> respectively are: (b)  $sp^3d$ ,  $sp^3d^2$ ,  $sp^3d^3$ 
  - (a)  $sp^2$ ,  $sp^3d$ ,  $sp^3d^2$ (c)  $sp^3d^2$ ,  $sp^3d$ ,  $sp^3d^3$
- (d)  $sp^2$ ,  $sp^3$ ,  $sp^3d$
- 3. Phosphorus pentachloride in gaseous state exists as a monomer. In solid state, it exists as PCl<sub>4</sub> and PCl<sub>6</sub> ions. The hybrid state of P atom in PCl<sub>5</sub> is  $sp^3d$ . The hybrid states of P atoms in PCl<sub>4</sub> and PCl<sub>6</sub> will be respectively:

#### Miscellaneous

- (a)  $sp^3d$ ,  $sp^3d^2$ (c)  $sp^3$ ,  $sp^3d^2$
- (b)  $sp^{3}$ ,  $sp^{3}d$ (d)  $sp^{3}d^{2}$ ,  $sp^{3}d$

- 4. The hybrid states of central atoms in NO<sub>2</sub>, NO<sub>2</sub> and NH<sub>4</sub>
  - (a)  $sp^3$ ,  $sp^2$ ,  $sp^3d$  respectively (b)  $sp^3$ ,  $sp^2$ ,  $sp^3$  respectively (c)  $sp^2$ ,  $sp^3$ ,  $sp^3$  respectively (d) sp,  $sp^2$ ,  $sp^3$  respectively
- 5. The hybrid states of carbon in diamond, graphite and acetylene respectively are:
  - (a)  $sp^2$ , sp,  $sp^3$ (c)  $sp^3$ ,  $sp^2$ , sp
- (b) sp,  $sp^2$ ,  $sp^3$ (d)  $sp^2$ ,  $sp^3$ , sp

## Thought 3

 $CuSO_4 \cdot 5H_2O + KCN (excess) \longrightarrow A (cyano complex)$  $CuSO_4.5H_2O + NH_4OH (excess) \longrightarrow B (ammine complex)$ 

- 1. The formulae of A and B are :
  - (a) K<sub>2</sub>[Cu(CN)<sub>4</sub>], [Cu(NH<sub>3</sub>)<sub>4</sub>]SO<sub>4</sub>
  - (b) K<sub>3</sub>[Cu(CN)<sub>4</sub>], [Cu(NH<sub>3</sub>)<sub>4</sub>]SO<sub>4</sub>
  - (c) K[Cu(CN)<sub>2</sub>], [Cu(NH<sub>3</sub>)<sub>6</sub>]SO<sub>4</sub>
  - (d) K<sub>3</sub>[Cu(CN)<sub>6</sub>], [Cu(NH<sub>3</sub>)<sub>6</sub>]SO<sub>4</sub>
- **2.** The IUPAC name of A and B are:
  - (a) potassium cupro cyanide, tetraammine cupric sulphate
  - (b) tetracyanopotassium cuprate(I), hexaammine copper(II) sulphate
  - (c) potassium tetracyano cuprate(I), tetraammine copper(II)
  - (d) potassium tetracyanocopper(I), tetraammine cuprate(II) sulphate
- 3. The hybridized state of copper in A and B are:
  - (a)  $sp^3$ ,  $dsp^2$ (c)  $dsp^2$ ,  $dsp^2$
- (b)  $sp^{3}$ ,  $sp^{3}$
- (d)  $sp^3d^2$ ,  $d^2sp^3$
- 4. Predict the magnetic nature of A and B:
  - (a) Both are diamagnetic
- (b) Both are paramagnetic
- (c) A is paramagnetic and B is diamagnetic
- (d) A is diamagnetic and B is paramagnetic
- 5. In the formation of complex A, which gas is evolved?
  - (a)  $H_2$
- (b) O<sub>2</sub>
- (c) HCN
- (d)  $(CN)_2$

## Thought 4

Colemanite + (A) 
$$\longrightarrow$$
 Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>  
Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub> + (B)  $\longrightarrow$  H<sub>3</sub>BO<sub>3</sub>  
H<sub>3</sub>BO<sub>3</sub>  $\xrightarrow{\text{Strongly} \atop \text{heated}}$  (C)

- 1. The formula of the colemanite mineral is:
  - (a) Ca<sub>2</sub>B<sub>6</sub>O<sub>11</sub>·5H<sub>2</sub>O
- (b) CaB<sub>4</sub>O<sub>7</sub>·NaBO<sub>2</sub>·8H<sub>2</sub>O
- (c) 2Mg<sub>3</sub>B<sub>8</sub>O<sub>15</sub>·MgCl<sub>2</sub>
- (d) Ca<sub>2</sub>B<sub>6</sub>O<sub>11</sub>·3H<sub>2</sub>O

- **2.** The compound (A) is:
  - (a) sodium carbonate
- (b) sodium oxide
- (c) sodium sulphate
- (d) carbon dioxide
- **3.** The compound (B) is:
  - (a) concentrated HCl
- (b) concentrated H<sub>2</sub>SO<sub>4</sub> (d) neither (a) nor (b)
- (c) either (a) or (b) **4.** The compound (C) is:
  - (a) B

(b)  $B_2O_3$ 

(c) BO<sub>2</sub>

- (d) BO<sub>3</sub>
- **5.** (*D*) and (*E*) are :
  - (a)  $H_2B_4O_7$ ,  $HBO_2$
- (b) HBO<sub>2</sub>, H<sub>2</sub>B<sub>4</sub>O<sub>7</sub>
- (c)  $H_4B_2O_5, H_2B_4O_7$
- (d)  $HBO_2$ ,  $H_5B_3O_7$
- 6. HBO3 is:
  - (a) Monobasic and weak Lewis acid
  - (b) Monobasic and weak Bronsted acid
  - (c) Monobasic and strong Lewis acid
  - (d) Tribasic and weak Bronsted acid

#### Thought 5

Potassium permanganate is the most important and well known salt of permanganic acid. It is prepared from pyrolusite ore. It is an oxidising agent in alkaline, neutral or acidic solutions. It is a purple coloured crystalline compound and fairly soluble in water.

- 1. Pyrolusite + KOH or  $K_2CO_3 = \frac{Fuscum an}{+ a little KNO_3}$ the product (A) is:
  - (a)  $Mn_3O_4$
- (b)  $Mn_2O_7$
- (c)  $K_2MnO_4$
- (d) KMnO<sub>4</sub>
- 2. The molecular mass of KMnO<sub>4</sub> is M. Its equivalent mass in acidic medium will be:
  - (a) M
- (b) M/2
- (c) M/3
- (d) M/5

3. For the redox reaction,

 $MnO_4^- + C_2O_4^{2-} + H^+ \longrightarrow Mn^{2+} + CO_2 + H_2O_3$ the correct coefficients of the reactants for the balanced reaction are:

]	$MnO_4^-$	$C_2O_4^{2-}$	$H^+$
(a)	2.	5	16
(b)	16	5	2
(c)	5	16	2
(d)	2	16	5

- 4. If equal volumes of 1M KMnO<sub>4</sub> and 1M K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> solutions are allowed to oxidise Fe(II) to Fe(III), then Fe(II) oxidised will be:
  - (a) more by KMnO<sub>4</sub>
- (b) more by K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub>
- (c) equal in both cases
- (d) cannot be compared
- 5. KMnO<sub>4</sub> is used as an oxidising agent in volumetric analysis in acidic medium. The acidic medium is maintained by the use of:
  - (a) dilute HCl
- (b) dilute HNO<sub>3</sub>
- (c) dilute H<sub>2</sub>SO<sub>4</sub>
- (d) concentrated H<sub>2</sub>SO<sub>4</sub>

## ANSWERS

#### **SECTION: 3**

#### Assertion-Reason Type Questions .....

Each question in this section contains Assertion (A) and **Reason** (R). Each question has four choices, out of which only one is correct. Mark your choice from the following options.

- (a) Both (A) and (R) are true and (R) is the correct explanation
- (b) Both (A) and (R) are true but (R) is not the correct explanation of (A).
- (c) (A) is correct but (R) is false.
- (d) (A) is false but (R) is ture.
- 16. (A) Halogens have maximum negative electron gain enthalpy in respective periods of the periodic table.
  - (R) Halogens have high effective nuclear charge.
- 17. (A) Between SiCl<sub>4</sub> and CCl<sub>4</sub>, only SiCl<sub>4</sub> reacts with water.
  - (R) SiCl<sub>4</sub> is ionic while CCl<sub>4</sub> is covalent.
- 18. (A) Smaller the size of an atom greater is its electronegativity.
  - (R) Electronegativity refers to the tendency of the atom to share electrons with the other atom.
- 19. (A) CaH<sub>2</sub> is known as hydrolith.
  - (R) It is an ionic hydride and on hydrolysis it evolves hydrogen.
- 20. (A) All noble gases are monoatomic.
  - (R) The electronic configuration of noble gases is either  $ns^2np^6$  or  $1s^2$  (helium).

#### **SECTION: 4**

#### Linked Comprehension Type Questions .....

This section contains a paragraph. Based upon paragraph, multiple choice questions have been given. Each question has 4 choices. Out of which only one is correct.

Molecular orbitals are formed by linear combination of atomic orbitals (LCAO). Two atomic orbitals can overlap forming two molecular orbitals, one of which lies at lower energy called bonding molecular orbital and other at higher energy called antibonding molecular orbitals. Pauli exclusion principle and Hund's rule are applicable for the filling of molecular orbitals. Molecules are said to be stable if number of electrons in bonding molecular orbitals are more than in the antibonding molecular orbitals. Molecular orbital theory can explain the magnetic behaviour of the molecules

21.	In a molecule, number of	of el	ectrons in bonding molecu	lar					
			electrons in the antibondi						
	molecular orbitals, hence:		ciculons in the unitodial	6					
	(a) a bond will be formed			П					
	(b) no bond will be formed								
	(c) information is not sufficient								
	(d) none of the above								
22.	Molecular orbital theory is	pref	erred over valence bond the	ory					
	as it can explain:								
	(a) bond strength		(b) geometry of molecule						
	(c) magnetic nature		(d) none of these						
23.	In which set of molecules	s, all	the species are paramagnet	ic?					
	(a) $B_2, O_2, N_2$		(b) $B_2$ , $O_2$ , $NO$						
	(c) $B_2, F_2, O_2$		(d) $B_2, O_2, Li_2$

	SECT		N:5						

#### Matrix-Match Type Questions .....

Each question contains statements given in two columns, which have to be matched.

24. Match List-II with List-II:

#### List-I List-II (Metal) (Procedure of extraction) (a) Iron (p) Carbon/carbon monoxide reduction method (b) Lead (a) Self reduction (c) Copper (r) Thermite process (d) Chromium (s) Hydrometallurgical process 25. Match Column-II with Column-II: Column-II

#### Column-I

- (a) Orthophosphorus acid
- (b) Sulphurous acid
- (c) Sulphuric acid
- (d) Perchloric acid
- (p) Monobasic acid
- (q) Dibasic acid
- (r) Oxidising agent
- (s) Reducing agent

## Practice Paper: 1 ....

1. (b)

$$\begin{array}{c} \text{CaCO}_{3} \longrightarrow \text{CaO} + \text{CO}_{2} \\ \text{(A)} \qquad \text{(B)} \\ \text{CaO} + \text{H}_{2}\text{O} \longrightarrow \text{Ca}(\text{OH})_{2} \\ \text{(C)} \\ \text{Ca}(\text{OH})_{2} + \text{CO}_{2} \longrightarrow \text{CaCO}_{3} + \text{H}_{2}\text{O} \\ \text{Milkiness} \\ \text{Ca}(\text{OH})_{2} + 2\text{NH}_{4}\text{Cl} \longrightarrow 2\text{NH}_{3} + \text{CaCl}_{2} + 2\text{H}_{2}\text{O} \\ \text{(D)} \\ \text{NH}_{3} + \text{H}_{2}\text{O} + \text{CO}_{2} \longrightarrow \text{NH}_{4}\text{HCO}_{3} \\ \text{(E)} \\ \text{NH}_{4}\text{HCO}_{3} + \text{NaCl} \longrightarrow \text{NaHCO}_{3} + \text{NH}_{4}\text{Cl} \\ \text{(F)} \\ 2\text{NaHCO}_{3} \longrightarrow \text{Na}_{2}\text{CO}_{3} + \text{CO}_{2} + \text{H}_{2}\text{O} \\ \end{array}$$

2. (c)

> Na<sub>2</sub>O<sub>2</sub> reacts with water and forms NaOH and H<sub>2</sub>O<sub>2</sub>. Sulphates of iron, aluminium and chromium are converted into corresponding hydroxides. Fe(OH)<sub>2</sub> is oxidised to Fe(OH)<sub>3</sub>, i.e., a brown insoluble precipitate. Al(OH)<sub>3</sub> dissolves forming NaAlO<sub>2</sub> (colourless) while Cr(OH)<sub>3</sub> is converted into Na<sub>2</sub>CrO<sub>4</sub> (yellow solution).

$$2Cr(OH)_3 + 4NaOH + 3O \longrightarrow 2Na_2CrO_4 + 5H_2O$$

3. (d)

> Bond angles in BeCl<sub>2</sub>, NH<sub>3</sub>, H<sub>2</sub>O and SnCl<sub>2</sub> are 180°, 106.5°, 104.5° and 119° respectively. O, S and Se belong to the same group and in their hydrides, there is  $sp^3$  hybridisation and bond angles of hydrides decrease down the group.

4. **(b)** 

$$O^{2-} + H_2O \longrightarrow 2OH^-$$
  
 $2O_2^{2-} + 2H_2O \longrightarrow 4OH^- + O_2$   
 $2O_2^- + 2H_2O \longrightarrow 2OH^- + H_2O_2 + O_2$ 

5. (a)

> B(OH)<sub>3</sub> does not act as a proton donor but behaves as a Lewis acid, i.e., it accepts a pair of electrons from OH ion.

$$B(OH)_3 + H \longrightarrow [B(OH)_4]^- + H^+$$

So, B(OH)<sub>3</sub> is not a protonic acid.

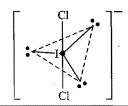

6.

HgI<sub>2</sub> dissolves in presence of KI forming a soluble complex.

$$\begin{array}{ccc} 2KI + HgI_2 & \longrightarrow & K_2HgI_4 \\ & & HgI_2 & \stackrel{Heat}{\longrightarrow} & Hg & + & I_2 \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & \\ & & & \\ & & \\ & & & \\ &$$

7.

 $ICl_2^-$  has linear shape. Iodine undergoes  $sp^3d$  hybridisation.

8. (a)

 $XeF_2$  is linear, xenon undergoes  $sp^3d$  hybridisation.

9.

The configuration of Cr is

$$1s^2$$
,  $2s^22p^6$ ,  $3s^23p^63d^5$ ,  $4s^1$ 

The Cr<sup>+</sup> ion has stable configuration and hence, requires more energy to remove an electron. Thus, the ionisation energy of Cr is highest amongst V, Mn and Fe.

10.

Greater the unpaired electrons, higher will be the paramagnetic character.

 $[MnCl_4]^{2-}$  5 unpaired electrons  $sp^3$ -hybridisation.  $[CoCl_4]^{2-}$  3 unpaired electrons  $sp^3$ -hybridisation.

 $[Fe(CN)_6]^{4-}$  no unpaired electron  $d^2sp^3$ -hybridisation.

11. (b, c, d)

XeO<sub>3</sub> has three  $\sigma$  and three  $\pi$ -bonds. Hence, this alternative is wrong.

12. (a, c)

13. (a, b, d)

	Hybridization	Structure
IF <sub>4</sub>	$sp^3d^2$	square planar
$[Cu(NH_3)_4]^{2+}$	$dsp^2$	square planar
XeF <sub>4</sub>	$sp^3d^2$	square planar
BF <sub>4</sub>	$sp^3$	Tetrahedral
$[Ni(CN)_4]^{2-}$	$dsp^2$	square planar

14. (b, c)

(a, d)

$$BaO_2 + H_2SO_4 \longrightarrow BaSO_4 + H_2O_2$$
  
 $Na_2O_2 + H_2SO_4 \longrightarrow Na_2SO_4 + H_2O_2$ 

MnO<sub>2</sub> and PbO<sub>2</sub> are not peroxides but dioxides.

20. (a)

16. (a) 17. (c) 18. (c) 19. (b)

21. (a)

If bond order is +ve, the bond will be formed.

22.

Molecular orbital theory explains the magnetic nature of the molecules and ions.

23. B<sub>2</sub> KK  $\sigma(2s)^2$ ,  $\overset{*}{\sigma}(2s)^2$ ,  $\pi(2p_x)^1$ ,  $\pi(2p_y)^1$  $O_2 \ KK \ \sigma(2s)^2, \ {}^*\sigma(2s)^2, \ (\sigma(2p_x)^2, \ \pi(2p_x)^2, \ \pi(2p_x)^2, \ \pi(2p_x)^1, \ \pi(2p_x)^1$ Paramagnetic NO KK  $\sigma(2s)^2$ ,  $\mathring{\sigma}(2s)^2$ ,  $\sigma(2p_z)^2$ ,  $\pi(2p_x)^2$ ,  $\pi(2p_y)^2$ ,  $\mathring{\pi}(2p_x)^1$ 

Paramagnetic

  - (R) Among the oxyacids of the same element, acidic nature increases with increase in the oxidation state of the element.

#### **SECTION: 4**

#### Linked Comprehension Type Questions .....

This section contains a paragraph. Based on this paragraph, multiple choice questions have been given. Each question has 4 choices. Out of which only one is correct.

Valence bond theory describes the bonding in complexes in terms of two electron coordinate covalent bonds resulting from the overlap of filled ligand orbitals with vacant metal hybrid orbitals that point in the direction of the ligands. This theory explains with reasonable success the formation, magnetic behaviour and geometrical shapes of coordination compounds. It, however, fails to provide a quantitative interpretation of

magnetic behaviour and explanation about optical properties of coordination compounds.

- 21. The correct order of magnetic moments (spin only value in BM) among the following is:
  - (a)  $[Fe(CN)_6]^{4-} > [CoCl_4]^{2-} > [MnCl_4]^{2-}$
  - (b)  $[MnCl_4]^{2-} > [Fe(CN)_6]^{4-} > [CoCl_4]^{2-}$
  - (c)  $[Fe(CN)_6]^{4-} > [MnCl_4]^{2-} > [CoCl_4]^{2-}$
- (d)  $[MnCl_4]^{2-} > [CoCl_4]^{2-} > [Fe(CN)_6]^{4-}$
- 22. The geometry of  $[Ni(CN)_4]^{2-}$  and  $[NiCl_4]^{2-}$  are:
  - (a) both square planar
  - (b) both tetrahedral □
    (c) tetrahedral and square planar respectively □
  - (d) square planar and tetrahedral respectively
- 23.  $[Fe(H_2O)_6]^{2+}$  and  $[Fe(CN)_6]^{4-}$  differ in:
  - (a) geometry, magnetic moment ☐
    (b) magnetic moment, colour ☐
  - (c) geometry, hybridisation
  - (d) hybridisation, number of unpaired electrons

## **SECTION: 5**

## Matrix-Match Type Questions .....

Each question contains statements given in two columns, which have to be matched.

24. Match List-I with List-II:

#### List-I

## List-II

- (a) Linear shape
- (p) CO<sub>2</sub>
- (b) sp-hybridisation
- (q)  $I_3^-$
- (c)  $sp^3d$ -hybridisation
- (r) C<sub>2</sub>H<sub>2</sub>
- (d) CS<sub>2</sub> is isostructural to
- (s) NCO
- 25. Match Column-II with Column-II:

#### Column-I

## Column-II

- (a) Ammonium nitrate
- (p) Fertilizer
- (b) Sodium thiosulphate
- (q) Purgative
- (c) Mercurous chloride

## Solwelon

## Practice Paper: 2 ....

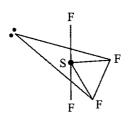

1. (c)

One lone pair

No lone pair

Three lone pairs

One lone pair

2. (b)

3. (a)

$$2MnO_4^- + 5C_2O_4^{2-} + 16H^+ \longrightarrow 2Mn^{2+} + 10CO_2 + 8H_2O_3$$

4. (d)

The degree of hydration depends on the size of the ion. The size of Mg<sup>2+</sup> ion is less than Na<sup>+</sup> ion and more than Be<sup>2+</sup>, Al<sup>3+</sup> and Li<sup>+</sup> ions. Hence, Hydration energy of Mg<sup>2+</sup> ion is greater than that of Na<sup>+</sup> ion.

5. (a)

$$\begin{split} I_2 + 10 \text{HNO}_3 &\longrightarrow 2 \text{HIO}_3 + 10 \text{NO}_2 + 4 \text{H}_2 \text{O} \\ \text{S} + 6 \text{HNO}_3 &\longrightarrow \text{H}_2 \text{SO}_4 + 6 \text{NO}_2 + 2 \text{H}_2 \text{O} \\ \text{P} + 10 \text{HNO}_3 &\longrightarrow 2 \text{H}_3 \text{PO}_4 + 10 \text{NO}_2 + 2 \text{H}_2 \text{O} \\ \text{C} + 4 \text{HNO}_3 &\longrightarrow \text{CO}_2 + 4 \text{NO}_2 + 2 \text{H}_2 \text{O} \end{split}$$

6. (d)

Bond order of 
$$O_2 = 2$$
,  $O_2^+ = 2.5$ ,  $O_2^- = 1.5$ ,  $N_2 = 3$ ,  $N_2^+ = 2.5$   
 $O_2^{2-} =$  no unpaired electrons, hence diamagnetic  
 $O_2^- =$  one unpaired electron, hence paramagnetic

7. (a)

$$2XeF_4 + 3H_2O \longrightarrow Xe + XeO_3 + F_2 + 6HF$$
  
 $CaCN_2 + 5H_2O \longrightarrow CaCO_3 + 2NH_4OH$ 

8. (b)

(D) is sodium hexametaphosphate, (NaPO<sub>3</sub>)<sub>6</sub>, which is called Graham's salt.

9. (c)

 $SiO_2$  is three dimensional giant. Silicon undergoes  $sp^3$  hybridisation.

10. (d)

$$\begin{split} 2\text{CuSO}_4 + 4\text{KI} & \longrightarrow \text{Cu}_2\text{I}_2 + 2\text{K}_2\text{SO}_4 + \text{I}_2 \\ & \text{White} \\ \text{HgI}_2 + 2\text{KI} & \longrightarrow \text{K}_2\text{HgI}_4 \\ \text{Pb(NO}_3)_2 + 2\text{KI} & \longrightarrow \text{PbI}_2 + 2\text{KNO}_3 \\ & \text{Yellow} \end{split}$$

11. (a, b, c)

Due to lanthanide contraction, the atomic radii of Zr and Hf, Mo and W are almost similar. In case of Co and Ni, increase in nuclear charge is almost balanced by shielding effect and as a result, both have nearly the same atomic radii.

12. (b, d)

NH<sub>3</sub> and H<sub>2</sub>O contain sp<sup>3</sup>-hybridised N and O atoms respectively.

13. (a, b, c)

 $NO_3^-$  has  $sp^2$  hybridisation. The bond angle is 120°.

 $NO_2$  and  $NO_2^-$  have  $sp^2$  hybridisation. Due to presence of one electron pair on  $NO_2^-$ , the repulsion on the bond pairs is more and thus, the angle is less, *i.e.*, 115° while in  $NO_2$ , one unshared electron is present on N-atom, the bond angle is more, *i.e.*, 132°.

NO<sub>2</sub><sup>+</sup> has sp-hybridisation, hence bond angle is 180°.

14. (c, d)

In contact process, either platinum or V<sub>2</sub>O<sub>5</sub> can be used as catalysts.

15. (b, c, d)

16. (c)

MgCl<sub>2</sub>·6H<sub>2</sub>O undergoes hydrolysis on heating.

$$MgCl_2 \cdot 6H_2O \longrightarrow Mg(OH)Cl + HCl + 5H_2O$$

17. (c)

In the solution, the following equilibria exists.

$$Cr_2O_7^{2-} + H_2O \Longrightarrow 2CrO_4^{2-} + 2H^+$$

In acidic medium,  $Cr_2Q_7^2$  ions exist which have orange colour while in basic medium,  $CrQ_4^2$  ions exist which have yellow colour.

18. (ď

The order of electron affinity is

Fluorine being the most electronegative always shows -1 oxidation state only.

19. (a)

Alkali metal atoms lose electrons which combine with ammonia molecules

$$M + (x + y)NH_3 \longrightarrow [M(NH_3)_x]^+ + e(NH_3)_y$$
Solvated

Solvated electron is responsible for blue colour.

20. (a)

21. (d)

[MnCl<sub>4</sub>]<sup>2-</sup> has tetrahedral geometry, *i.e.*, 5 unpaired electrons are present.

$$Mn^{2+}$$
  $\uparrow \uparrow \uparrow \uparrow \uparrow \uparrow \uparrow$   $\downarrow g$   $\downarrow g$  hybridisation

 $[Fe(CN)_6]^{4-}$  has octahedral geometry, i.e., it has no unpaired electron.

[CoCl<sub>4</sub>]<sup>2-</sup> has tetrahedral geometry, i.e., it has 3 unpaired electrons.

22. (d)

CN<sup>-</sup> is a strong ligand. Electrons in rearranged in 3d-orbitals of Ni<sup>2+</sup> ion. It undergoes  $dsp^2$  hybridisation in forming [Ni(CN)<sub>4</sub>]<sup>2-</sup> complex.

Cl<sup>-</sup> is a weak ligand. Electrons are not rearranged in 3d-orbitals of Ni<sup>2+</sup> ion. It undergoes  $sp^3$  hybridisation in forming [NiCl<sub>4</sub>]<sup>2-</sup> complex.

23. (b)

 $[Fe(H_2O)_6]^{2+}$  is paramagnetic while  $[Fe(CN)_6]^{4-}$  is diamagnetic.  $[Fe(H_2O)_6]^{2+}$  has pale green colour while  $[Fe(CN)_6]^{4-}$  has yellow colour

**24.** (a-p, q, r, s); (b-p, r, s); (c-q); (d-p)

25. (a-p, t); (b-r, s); (c-q); (d-s); (e-t)

# Practice Paper —3 ....

## **SECTION: 1**

## Straight Objective Type Questions .....

This section contains 10 multiple choice questions. Each question has 4 choices (a), (b), (c) and (d). Out of which only one is correct.

1.

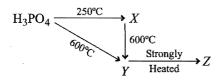

atom is:

(a)  $[Co(NH_3)_6]^{3+}$ 

(c)  $[Cr(H_2O)_6]^{3\nu}$ 

(a)  $Al^{3+} + 3Cl^{-}$ 

When dissolved in water, it gives:

	X, $Y$ and $Z$ are :				
	•				
	(a) $H_4P_2O_7$ , $HPO_3$ and $P_4O_{10}$ respectively	느			
	(b) HPO <sub>3</sub> , H <sub>4</sub> P <sub>2</sub> O <sub>7</sub> and P <sub>4</sub> O <sub>10</sub> respectively				
	(c) H <sub>4</sub> P <sub>2</sub> O <sub>7</sub> , H <sub>3</sub> PO <sub>3</sub> and P <sub>4</sub> O <sub>6</sub> respectively				
	(d) H <sub>4</sub> P <sub>2</sub> O <sub>7</sub> , HPO <sub>3</sub> and P <sub>4</sub> O <sub>6</sub> respectively				
2.	The types of bonds present in CuSO <sub>4</sub> ·5H <sub>2</sub> O are:				
	(a) electrovalent and covalent				
	(b) electrovalent and coordinate covalent				
	(c) electrovalent, covalent, coordinate and hydrogen bonds				
	(d) covalent and coordinate covalent				
3.	For $A + KOH + Air \xrightarrow{Heat} B$				
	$B + O_3 + H_2O \longrightarrow C$ (Pink)				
	Which of the following is correct?				
	(a) A is black (MnO <sub>2</sub> ), B is blue ( $K_2MnO_4$ ) and C is	pink			
	(KMnO <sub>4</sub> )				
	(b) A is black (MnO <sub>2</sub> ), B is green (K <sub>2</sub> MnO <sub>4</sub> ) and C is	pink			
	(KMnO <sub>4</sub> )				
	(c) A is colourless (MnO <sub>2</sub> ), B is blue ( $K_2MnO_4$ ) and C is	pink			
	(KMnO <sub>4</sub> )				
	(d) A is green (MnO <sub>2</sub> ), B is green (K <sub>2</sub> MnO <sub>4</sub> ) and C is	pink			
	(KMnO <sub>4</sub> )				
4.	The complex ion which has no d-electrons in the central n	netal			

 $\Box$  (b)  $[Fe(CN)_6]^{3-}$ 

 $\Box$  (b)  $[Al(H_2O)_6]^{3+} + 3Cl^{-}$ 

☐ (d) [MnO<sub>4</sub>]

5. Aluminium chloride exists as dimer, Al<sub>2</sub>Cl<sub>6</sub> in solid state as well as in solution of non-polar solvents such as benzene.

(c)  $[Al(OH)_6]^{3-} + 3HCl \square$  (d)  $Al_2O_3 + 6HCl$ 

are correct?

	(a) Fe(CO) <sub>5</sub>	L	(b) [FeCl <sub>4</sub> ]	L
	(c) $Fe_4[Fe(CN)_6]_3$		(d) $[Fe(H_2O)_5NO]^{2+}$	
7.	Consider the following	ng compl	ex	
	[Co(NH <sub>3</sub> ) <sub>5</sub> CO <sub>3</sub> ]ClO <sub>4</sub>			٠
	The coordination number, oxidation number, number of			her of
		•	paired $d$ -electrons on the	
	are respectively:	oci oi un	paried a-electrons on the	. metai

6. Iron exhibits the +1 oxidation state in:

	<ul> <li>(a) Hydration energy of Sr<sup>2+</sup> is greater than that of Be<sup>2+</sup>□</li> <li>(b) CaCO<sub>3</sub> decomposes at a higher temperature than BaCO<sub>3</sub></li> </ul>	SEC	TION: 4	
	(c) Ba(OH) <sub>2</sub> is stronger base than Mg(OH) <sub>2</sub>	Linked Comprehension Type Questions  This section contains a paragraph. Based on the paragraph, multiple choice questions have been given. Each question has 4 choices, out of which only one is correct.  When the halogen atom combines with an element of lesser electronegativity, it shows -1 oxidation state. On the other hand, when it combines with an element having higher electronegativity it exhibits +1 oxidation state. Chlorine and higher halogens show positive oxidation states as the electrons in the valency shell can be promoted to vacant d-orbitals. These elements can show +3.		
	SECTION: 3	_	show positive oxidation state?	_

# Solution

#### Practice Paper: 3....

1. (a) 
$$2H_{3}PO_{4} \xrightarrow{250^{\circ}C} H_{4}P_{2}O_{7} + H_{2}O$$

$$(X)$$

$$H_{3}PO_{4} \xrightarrow{600^{\circ}C} HPO_{3} + H_{2}O$$

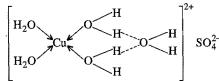

$$(Y)$$

$$H_{4}P_{2}O_{7} \xrightarrow{600^{\circ}C} 2HPO_{3} + H_{2}O$$

$$(Y)$$

$$4HPO_{3} \xrightarrow{Strongly} P_{4}O_{10} + 2H_{2}O$$

2. (c) CuSO<sub>4</sub>·5H<sub>2</sub>O can be represented as :

3. (b) 
$$2\text{MnO}_2 + 4\text{KOH} + \text{O}_2 \longrightarrow 2\text{K}_2\text{MnO}_4 + 2\text{H}_2\text{O}$$

$$(A) \qquad (air) \qquad (B) \qquad Green$$
 $2\text{K}_2\text{MnO}_4 + \text{O}_3 + \text{H}_2\text{O} \longrightarrow 2\text{KMnO}_4 + 2\text{KOH} + \text{O}_2$ 

$$(C) \qquad Pink$$

- **4.** (d) In  $[MnO_4]^-$ ,  $Mn^{7+}$  ion has the configuration [Ar]  $3d^04s^0$ , *i.e.*, all the 3d electrons and 4s electrons have been lost.
- 5. **(b)**  $Al_2Cl_6 + 12H_2O \rightleftharpoons 2[Al(H_2O)_6]^{3+} + 6Cl^{-1}$
- 6. (d)

#### Oxidation number

 $\begin{aligned} &\text{Fe(CO)}_5 & & 0 \\ &[\text{FeCl}_4]^\top & +3 \\ &\text{Fe}_4[\text{Fe(CN)}_6]_3 & +3, +2 \text{ respectively} \\ &[\text{Fe(H}_2\text{O)}_5\text{NO}]^{2+} & +1 \end{aligned}$ 

 $x + 5 \times 0 + 1 = +2$  or x = +1

- 7. (a)
  - Coordination number

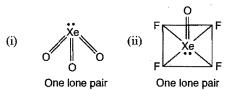

Oxidation number 3  $\frac{3d}{3} + \frac{4s}{3} + \frac{4s}{3}$ 

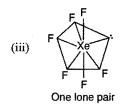

No. of *d*-electrons 6 No. of unpaired electrons 0

8. (a)

6

9. (d)

10. (c)  $\begin{array}{c} \operatorname{Cl}_2 + \operatorname{H}_2\operatorname{O} \longrightarrow \operatorname{HCl} + \operatorname{HClO} \\ (X) \\ \operatorname{HCl} + \operatorname{AgNO}_3 \longrightarrow \operatorname{AgCl} + \operatorname{HNO}_3 \\ \operatorname{White ppt.} \\ \operatorname{2HCl} + \operatorname{Mg} \longrightarrow \operatorname{MgCl}_2 + \operatorname{H}_2 \\ (Y) \end{array}$ 

11. (a, d)  $I_3$ —Linear;  $[Ni(CN)_4]^2$ —square planar

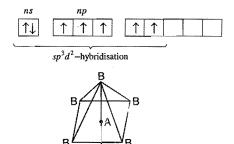

- 12. (a, b)
- 13. (c, d)
- 14. (a, b, c) CO<sub>2</sub> and SO<sub>2</sub> turn lime water milky.
- 15. (a, b, c)
- 16. (d) LiCl is less ionic than NaCl as Li<sup>+</sup> ion is smaller than Na<sup>+</sup> ion. Hence, it has more polarising power than Na<sup>+</sup> ion.
- 17. (a)
- 18. (b) Both statements are correct.

$$N_2^+$$
, B.O. =  $\frac{9-4}{2}$  = 2.5  
 $N_2^-$ , B.O. =  $\frac{10-5}{2}$  = 2.5

 $N_2^+$  is more stable than  $N_2^-$  as it contains less number of antibonding electrons.

- 19. (b) Both the statements are correct.
- 20. (a) Presence of unpaired electron in superoxides of alkali metals make them paramagnetic.
- (b) Fluorine being highest electronegative element shows only -1 oxidation state.
- 22. (c)  $HIO_4$ , +1+x-8=0or x=+7
- 23. (a)

Second excited state

	his section contains 9 multiple choice questions. Each tion has 4 choices (a), (b), (c) and (d). Out of which only one orrect.  An inorganic compound liberates oxygen when heated, turns an acid solution of KI brown and decolourises acidified KMnO4 solution. The substance is:  (a) H2O2	sight Objective Type Questions

$$K_{2}MnO_{4} \xrightarrow{H_{2}SO_{4}} KMnO_{4}$$

$$(B)$$
Purple
$$2KMnO_{4} + H_{2}SO_{4} \longrightarrow Mn_{2}O_{7} + H_{2}O + K_{2}SO_{4}$$

$$(conc.) \qquad (C)$$

$$2Mn_{2}O_{7} \longrightarrow 4MnO_{2} + 3O_{2}$$

$$(D)$$

The cation in (D) is  $M^{4+}$ . E.C. of  $M^{4+} = [Ar]3d^3$ 

Thus, number of unpaired electrons in  $M^{4+} = 3$ .

16. (1) 
$$Xe + 3F_2 \xrightarrow{\text{High Press.}} XeF_6$$
  
 $1:20 \xrightarrow{\text{Ni-tube}} XeO_3 + 6HF$   
 $(X)$ 

	58	5 <i>p</i>	·	5 <i>d</i>	
E.C. of Xe in ground state	ŤΨ	11 11 11	,		
E.C. of Xe in excited state	11	$\uparrow$ $\uparrow$ $\uparrow$	1 1	1	
	$sp^3$ hyb.				

In XeO<sub>3</sub>, Xenon undergoes sp<sup>3</sup> hybridisation giving tetrahedral configuration. There are three sigma bonds with three hybrid orbitals and three  $\pi$ -bonds along with one lone pair of electrons.

17. (4) 
$$MCl_x + xAgNO_3 \longrightarrow xAgCl + M(NO_3)_x$$

Number of moles of AgNO3 used for 0.1 mole of MCl<sub>x</sub>  $=\frac{500}{1000} \times 0.8 = 0.4 \text{ mol.}$ 

Thus, 1 mole of MClx requires 4 moles of AgNO<sub>3</sub>

Calcium carbide on hydrolysis gives acetylene.

#### 19. (a)

**(b)** 20.

#### 21. (c)

NaCl and CaCl2 are added to make the fused mass as good conductor and also to lower the fusion temperature of anhydrous MgCl<sub>2</sub>.

**22.** 
$$(a-q, s), (b-r), (c-q, s), (d-p, s)$$

#### 25. (c)

#### 26. (a)

On heating polyhalide, the smallest halogen remains attached with the metal because this forms a salt with higher lattice energy.

#### 27. (c)

Iodine undergoes  $sp^3d^2$  hybridization giving octahedral configuration having three hybrid orbitals with single electron each, one vacant hybrid orbital and two hybrid orbitals have paired electrons each. The ion consists three covalent bonds, one coordinate bond and two lone pairs.

Yb: 70 [Xe] 
$$4f^{14}$$
,  $6s^2$   
Lu: 71 [Xe]  $4f^{14}$ ,  $5d^1$ ,  $6s^2$ 

Lu: 71 [Xe] 
$$4f^{14}$$
,  $5d^1$ ,  $6s^2$ 

#### 30. (d)

Lu3+ is the smallest in size.

Stre	aight Objective Type Questions	(d) no unpaired electron and is diamagnetic.		
	his section contains 9 multiple choice questions. Each	SECTION: 2		
ques	stion has 4 choices (a), (b), (c) and (d). Out of which only one			
is co	orrect.	Straight Multiple Choice Objective Type Questions		
1.	HNO <sub>3</sub> acid solutions A and B have concentrations 0.5 N and			
	0.1 N respectively. The volume of solutions A and B required	This section contains 4 multiple choice questions. Each		
	to make 2 L of 0.2 N HNO <sub>3</sub> acid solution is:	question has 4 choices. Out of which one or more than one may		
	(a) $0.5 \text{ L of } A \text{ and } 1.5 \text{ L of } B$	be correct.		
	(b) 1.5 L of A and 0.5 L of B	10. Which of the following are correct statements?		
	(c) 1.0 L of A and 1.0 L of B	(a) Solid PCl <sub>5</sub> exists as [PCl <sub>4</sub> ] <sup>+</sup> [PCl <sub>6</sub> ] <sup>-</sup>		
	(d) 0.75 L of A and 1.25 L of B	(b) Solid PBr <sub>5</sub> exists as [PBr <sub>4</sub> ] <sup>+</sup> Br \qquad \qquad		
2.	The purity of H <sub>2</sub> O <sub>2</sub> in a given sample is 85%. The weight of	(c) Solid N <sub>2</sub> O <sub>5</sub> exists as [NO <sub>2</sub> ] <sup>+</sup> [NO <sub>3</sub> ] <sup>-</sup>		
	impure sample of H <sub>2</sub> O <sub>2</sub> which requires 10 mL of 1N KMnO <sub>4</sub>	(d) Oxides of phosphorus P <sub>2</sub> O <sub>3</sub> and P <sub>2</sub> O <sub>5</sub> exist as monomers		
	in a titration in acidic medium is:			
	(a) $2g$ $\square$ (b) $0.2g$ $\square$	11. Which of the following isomerisms are shown by the complex		
	(c) $0.17  \mathrm{g}$	[CoCl <sub>2</sub> (OH) <sub>2</sub> (NH <sub>3</sub> ) <sub>2</sub> ]Br?		
3.	TlI <sub>3</sub> is an ionic compound which furnishes the following ions:	(a) Ionisation		
	(a) $TI^{3+}$ and $I_3^ \Box$ (b) $TI^{3+}$ and $I^ \Box$	(c) Geometrical		
	(c) $Tl^+$ and $I^ \Box$ (d) $Tl^+$ and $I_3^ \Box$	12. CS <sub>2</sub> is isostructural with :		
4.	$Be_2C + 4H_2O \longrightarrow 2X + CH_4$	(a) BeCl <sub>2</sub>		
	$X + 2$ NaOH $\longrightarrow Y + 2$ H <sub>2</sub> O	(a) $C_2H_2$ $\Box$ (b) $C_2H_2$ $\Box$ (c) $C_2H_2$ $\Box$ (d) $C_2H_2$ $\Box$		
	X and Y formed in the above two reactions are:	13. Which of the following represents the same element?		
	(a) BeCO <sub>3</sub> and Be(OH) <sub>2</sub> respectively $\Box$	(a) 106		
	(b) Be(OH) <sub>2</sub> and Na <sub>2</sub> BeO <sub>2</sub> respectively	(c) Ha		
	(c) $[Be(OH)_4]^{2-}$ and $Be(OH)_2$ respectively	(c) Im — — (d) of (sourcestum) —		
	(d) BeO and Be(OH) <sub>2</sub> respectively $\Box$			
5.	Which of the following species represents the example of	SECTION: 3		
	dsp <sup>2</sup> hybridization?			
:	(a) $[Fe(CN)_6]^3$	Integer Answer Type Questions		
	(c) $[Ag(CN)_2]^{-}$ $\Box$ (d) $[Co(CN)_6]^{3-}$ $\Box$			
6.	The fluoride of xenon with zero dipole moment is:	This section contains 4 questions. The answer to each of the		
	(a) $XeF_6$	questions is a single-digit integer ranging from 0 to 9.		
_	(c) $XeF_4$	14. An acid is formed by heating orthophosphoric acid at		
7.	A greenish yellow gas reacts with an alkali metal hydroxide	250-260°C. The number of series of salts formed by this acid		
	to form a halate which can be used in fireworks and safety	are:		
	matches. The gas and halate respectively are:	15. How many moles of carbon monoxide are obtained when		
	(a) $Cl_2$ , $KClO_3$	one mole of potassium ferrocyanide is heated with conc.		
_	(c) I <sub>2</sub> , KIO <sub>3</sub>	sulphuric acid?		
8.	In BF <sub>3</sub> , the B-F bond length is 1.30Å. When BF <sub>3</sub> is allowed	16. The ratio of lone pairs and the number of S-S bonds in S <sub>8</sub>		
•	to be treated with Me <sub>3</sub> N, it forms an adduct, Me <sub>3</sub> N $\rightarrow$ BF <sub>3</sub> ,	molecule is:		
	the bond length of B-F in the adduct is:	17. For the reaction,		
	(a) greater than 1.30 Å	$M^{x+} + \text{MnO}_{4}^{-} \longrightarrow MO_{3}^{-} + \text{Mn}^{2+} + 1/2 O_{2}$		
•	(c) equal to 1.30 Å	If one mole of $MnO_4^-$ oxidises 1.67 moles of $M^{x+}$ to $MO_3^-$ ,		
У.	Dinitrogen tetroxide (N <sub>2</sub> O <sub>4</sub> ) has:	then the value of $x$ in the reaction would be:		
	(a) two unpaired electrons and is paramagnetic			

#### **SECTION: 4**

#### Assertion-Reason Type Questions .....

Each question in this section contains Assertion (A) and Reason (R). Each question has four choices, out of which only one is correct. Mark your choice from the following options.

- (a) Both (A) and (R) are true and (R) is the correct explanation of (A).
- (b) Both (A) and (R) are true but (R) is not the correct explanation of (A).
- (c) (A) is true but (R) is false.
- (d) (A) is false but (R) is true.
- 18. (A) CO and  $O_2$  both combine with haemoglobin.
  - (R) CO has greater affinity for haemoglobin than O<sub>2</sub>.
- 19. (A) Normal hydrogen consists of a mixture of two forms, ortho (75%) and para (25%).
  - (R) Pure ortho form can be obtained at low temperature but pure para form can not be obtained.
- 20. (A) KCN gives K<sub>3</sub>Cu (CN)<sub>4</sub> complex compound with CuSO<sub>4</sub> solution.
  - (R) KCN reduces Cu<sup>2+</sup> to Cu<sup>+</sup> and then forms a complex compound.
- 21. (A) The first ionisation energy of Be is greater than that of B.
  - (R) 2p-orbital is lower in energy than 2s-orbital.

#### **SECTION: 5**

#### Matrix-Match Type Questions .....

This section contains 3 questions. Each question contains statements given in two columns, which have to be matched.

22. Match Column-I with Column-II.

## Column-I

#### Column-II

- (a) K<sub>4</sub>Fe(CN)<sub>6</sub>
- (p) Geometrical isomers
- (b)  $[Pt(NH_3)_4Cl_2]Br_2$
- (q) Paramagnetic
- (c)  $[Co(NH_3)_3Cl_3]$
- (r) Diamagnetic
- (d)  $[NiCl_4]^{2}$
- (s) Metal ion with +2 oxidation state
- 23. Match Column-I with Column-II.

#### Column-I

#### Column-II

(a) Brass

- (p) Copper
- (b) Bronze
- (q) Zinc
- (c) German silver
- (r) Nickel
- (d) Constantan
- (s) Tin
- 24. Match Column-I with Column-II.

#### Column-I

#### Column-II

- (a)  $4s^2 4p^6$
- (p) Metal
- (b)  $6s^1 4f^{14} 5d^{10}$
- (q) Non-metal

(c)  $4f^1 5s^2 5p^6 5d^1 6s^2$ (d)  $4s^2 3d^{10} 4p^5$ 

在一時間的事物也們將經過學在一個

- (r) Noble gas
- (s) Lanthanide

 $\Box$ 

#### **SECTION: 6**

#### Linked Comprehension Type Questions .....

This section contains 2 paragraphs. Based on each paragraphs, 3 multiple choice questions have to be answered. Each question has four choices, out of which only one is correct.

#### Comprehension: 1

Xenon having nearly the same ionisation energy as oxygen forms a large number of compounds like xenon fluorides, oxyfluorides, oxides and perxenates. Xenon exhibits various oxidation states from +2 to +8. Perxenates are powerful oxidants and  $XeO_3$  is a powerful explosive.

- **25.** The hybridization of Xe in XeO<sub>2</sub>F<sub>2</sub> and its shape are : (a)  $sp^3d^2$ , T-shaped  $\Box$  (b)  $sp^3d$ , see-saw  $\Box$ 
  - (c)  $sp^3$ , tetrahedral  $\Box$  (d)  $sp^3d$ , V-shape
- **26.** The number of lone pairs of electrons in XeF<sub>2</sub>, XeF<sub>4</sub>, XeF<sub>6</sub> and XeOF<sub>2</sub> are respectively:
- 27. The wrong statement is:
  - (a) Perxenates are  $[XeO_6]^{4-}$
  - (b) Perxenates are coloured and strong reductants
  - (c) Oxidation number of Xe in perxenates is + 8
  - (d) Perxenates are formed by hydrolysis of xenon hexafluoride with strong alkalies.

#### Comprehension: 2

Metal nitrate (A) on heating decomposes, leaving a solid residue (B) which goes into solution with dilute HCl. The solution of (B) gives a white precipitate with ammonium carbonate solution. The precipitate is dissolved in dilute HCl and the solution is treated with K<sub>2</sub>CrO<sub>4</sub> solution to give a yellow precipitate (C). The solution (B) reacts with dil. H<sub>2</sub>SO<sub>4</sub> also gives a white precipitate (D), insoluble in dilute HCl and HNO<sub>3</sub>. The precipitate (D) is a part of a white pigment lithopone.

- 28. The compound (D) is :

  (a) PbSO<sub>4</sub> □ (b) ZnSO<sub>4</sub> □

  (c) MgSO<sub>4</sub> □ (d) BaSO<sub>4</sub> □
- - (c)  $CaCrO_4$   $\Box$  (d) none of these  $\Box$ 1. The metal nitrate (A) is:
    - (a)  $Ba(NO_3)_2$   $\Box$  (b)  $Pb(NO_3)_2$   $\Box$  (c)  $Ca(NO_3)_2$   $\Box$  (d)  $KNO_3$   $\Box$

# Solution

121

## Practice Paper: 5 ....

1. (a)

Let xL of A and yL of B be mixed to form 2L of 0.2 N HNO<sub>3</sub> solution

$$x + y = 2$$
 ... (i)  
 $y \times 0.1 = 2 \times 0.2$  ... (ii)

 $x \times 0.5 + y \times 0.1 = 2 \times 0.2$ 

Solving both the equations, we get y = 1.5 L and x = 0.5 L

2. (b)

$$1 \text{ N KMnO}_4 = 10 \text{ mL } 1 \text{ N H}_2\text{O}_2$$

Mass of 
$$H_2O_2 = \frac{17 \times 10}{1000} = 0.17 \text{ g}$$

Mass of impure  $H_2O_2$  soln. =  $\frac{1000}{85} \times 0.17 = 0.2$  g

3. (d)

$$TII_3 \Longrightarrow TI^+ + I_3^-$$

4. (b)

5. (b)

Ni<sup>2+</sup>

$$[Ag(CN)_2]^- - sp$$
 hyb.  
 $[Co(CN)_6]^{3-} - d^2sp^3$  hyb.

6. (c)

 $XeF_4$  is symmetrical with square planar shape, so the resultant dipole moment is zero.

XeF<sub>4</sub>

KClO<sub>3</sub> is used in fireworks and safety matches.

8. (

In BF<sub>3</sub>, there is back bonding in between boron and fluorine which imparts double bond character.

As BF<sub>3</sub> forms an adduct, the back bonding disappears and hence, double bond character disappears and the bond length between boron and fluorine increases a bit.

9. (d)

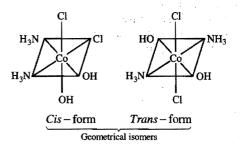

nakoni kunasan Kabi Islani kunak

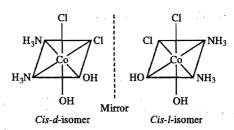

10. (a, b, c)

Oxides of phosphorus are dimeric in nature, P<sub>4</sub>O<sub>6</sub> and P<sub>2</sub>O<sub>10</sub>.

11. (a, c, d

[CoCl<sub>2</sub>(OH)<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>]Br and [CoClBr(OH)<sub>2</sub>(NH<sub>3</sub>)<sub>2</sub>]Cl are ionisation isomers.

12. (a, c)

The structure of  $CS_2$  is linear S=C=S, similarly the structures of  $HgCl_2$  and  $C_2H_2$  are linear, Cl-Hg-Cl,  $HC\equiv CH$ .  $SnCl_2$  and  $NO_2$  have angular structures.

13. (a, b, d)

14. (4)

H<sub>4</sub>P<sub>2</sub>O<sub>7</sub> (Pyrophosphoric acid) is formed when H<sub>3</sub>PO<sub>4</sub> is heated at 250-260°C.

$$2H_3PO_4 \xrightarrow{250-260^{\circ}C} H_4P_2O_7 + H_2O_7$$

This acid contains 4-OH groups i.e., 4 ionisable hydrogen atoms, thus it can form four series of salts.

15. (6)

$$K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O \longrightarrow 2K_2SO_4 + FeSO_4 + 6CO + 3(NH_4)_2SO_4$$

16. (2)

 $S_8$  molecule has the following structure. Each sulphur atom is in  $sp^3$  hybridized state.

Ratio = 16/8 = 2

Number of lone pairs = 16 Number of S—S bonds = 8 17. (2)

$$MnO_4^- + 5e \longrightarrow Mn^{2+}$$

Since 1 mole of  $MnO_4^-$  accepts 5 moles of electrons, therefore, 5 moles of electrons are lost by 1.67 moles of  $M^{x+}$ 

:. 1 mole of  $M^{x+}$  will lose electrons =  $\frac{5}{1.67}$  = 3 mol (approx.)

Since  $M^{x+}$  changes to  $MO_3^-$  by losing three electrons.

$$x = 5-3 = 2$$

18. (b) 19. (c)

20. (a)

21. (c)

Be has fully filled  $2s^2$ -orbital which gives a relatively more stable electronic configuration.

**22.** (a-r, s); (b-p, r); (c-p, r); (d-q, s)

23. (a-p, q); (b-p, s); (c-p, q, r); (d-p, r)

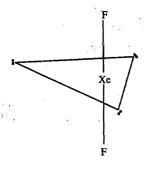

24. (a-q, r); (b-p); (c-p, s); (d-q)

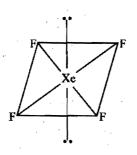

25. (b)

sp<sup>3</sup>d hybridization—See-saw shape

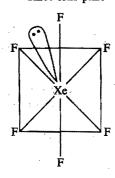

26. (a)

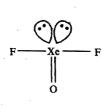

Three lone pairs

Two lone pairs

One lone pair

Two lone pairs

27. (b)

28. (d) 29. (b) 30. (a)

#### For Comprehension: 2
